NOVEL ANTI-INFLAMMATORY AGENTS

[001] This application claims the benefit of U.S. Provisional Application No. 61/161,089, filed March 18, 2009, which is incorporated by reference in its entirety.

[002] The present invention relates to novel compounds that are useful in regulating the expression of interleukin-6 (IL-6) and/or vascular cell adhesion molecule-1 (VCAM-1), and their use in the treatment and/or prevention of cardiovascular and inflammatory diseases and related disease states, such as, for example, atherosclerosis, asthma, arthritis, cancer, multiple sclerosis, psoriasis, and inflammatory bowel diseases, and autoimmune disease(s). The invention also includes pharmaceutical compositions comprising the novel compounds, as well as methods for their preparation.

[003] Coronary heart disease (CHD) remains a leading cause of death in industrialized nations. A primary cause of CHD is atherosclerosis, a disease characterized by the deposition of lipids in the arterial vessel wall, resulting in a narrowing of the vessel passages and, ultimately leading to hardening of the vascular system.

[004] It is generally accepted that atherosclerosis can begin with local injury to the arterial endothelium, followed by proliferation of arterial smooth muscle cells from the medial layer to the intimal layer, along with the deposition of lipids and the accumulation of foam cells in the lesion. As the atherosclerotic plaque develops, it progressively occludes more of the affected blood vessel and can eventually lead to ischemia or infarction. Thus, there is a continued effort to develop treatments to inhibit or prevent the progression of atherosclerosis in patients in need thereof.

[005] Cardiovascular disease has been linked to several causative factors, including hypercholesterolemia, hyperlipidemia, and the expression of vascular cell adhesion molecule-1 (VCAM-1) in vascular endothelial cells. VCAM-1 promotes the adhesion of lymphocytes, monocytes, eosinophils, and basophils. Certain melanoma cells can use VCAM-1 to adhere to the endothelium, and VCAM-1 may participate in monocyte recruitment to atherosclerotic sites. As a result, VCAM-1 is of interest as a drug target.
[006] The VCAM-1 gene is a member of the immunoglobulin (Ig) superfamily and encodes a cell-surface sialoglycoprotein expressed by cytokine-activated endothelial cells. This type-1 membrane protein mediates leukocyte-endothelial cell adhesion and signal transduction, and may play a role in the development of atherosclerosis and rheumatoid arthritis. VCAM-1, also known as CD106, has several roles in the immune system. The VCAM-1 protein contains six or seven immunoglobulin domains, and is expressed in both large and small vessels only after endothelial cells are stimulated by cytokines.

[007] Adhesion of leukocytes to the endothelium represents a fundamental, early event in many inflammatory conditions, including atherosclerosis, autoimmune disorders, and bacterial and viral infections. Leukocyte recruitment to the endothelium begins when inducible adhesion molecule receptors on the surface of endothelial cells interact with their counter-receptors on immune cells. Vascular endothelial cells determine which type(s) of leukocyte(s) (e.g., monocytes, lymphocytes, neutrophils) are recruited, by selectively expressing specific adhesion molecules, such as VCAM-1, intracellular adhesion molecule-1 (ICAM-1), and E-selectin.

[008] In the early stage of the atherosclerotic lesion, there is localized endothelial expression of VCAM-1 and selective recruitment of mononuclear leukocytes that express the integrin counter-receptor VLA-4. Because of the selective expression of VLA-4 on monocytes and lymphocytes, but not neutrophils, VCAM-1 is important in mediating the selective adhesion of mononuclear leukocytes. Subsequent conversion of leucocytes to foamy macrophages results in the synthesis of a wide variety of inflammatory cytokines, growth factors, and chemoattractants that help expand leukocyte and platelet recruitment, smooth muscle cell proliferation, endothelial cell activation, and the extracellular matrix synthesis characteristic of maturing atherosclerotic plaques.

[009] VCAM-1 is also a mediator in inflammatory diseases. For example, it is known that the expression of VCAM-1 and ICAM-1 are increased in asthmatics (Pilewski et al. (1995) Am. J. Respir. Cell Mol. Biol. 12, 1-3; Ohkawara et al. (1995) Am J. Respir. Cell Mol. Biol. 12, 4-12). Further examples of non-cardiovascular inflammatory diseases mediated by VCAM-1 include rheumatoid and osteoarthritis, asthma, dermatitis, and multiple sclerosis. Blocking
the integrin receptors for VCAM-1 and ICAM-1 (VLA-4 and LFA-1, respectively) suppresses both early- and late-phase responses in an ovalbumin-sensitized rat model of allergic airway responses (Rabb et al. (1994) Am. J. Respir. Care Med. 149, 1186-1191). There is also increased expression of endothelial adhesion molecules, including VCAM-1, in the microvasculature of rheumatoid synovium (Koch et al. (1991) Lab. Invest. 64, 313-322; Morales-Ducret et al. (1992) Immunol. 149, 1421-31).

[010] Neutralizing antibodies directed against VCAM-1 or its counter receptor, VLA-4, can delay the onset of diabetes in a mouse model (NOD mice), which spontaneously develop the disease (Yang et al. (1993) Proc. Natl. Acad. Sci. USA 90, 10494-10498; Burkly et al. (1994) Diabetes 43, 523-534; Baron et al. (1994) J. Clin. Invest. 93, 1700-1708). Monoclonal antibodies to VCAM-1 can also have beneficial effects in animal models of allograft rejection, suggesting that inhibitors of VCAM-1 expression may also have utility in preventing transplant rejection (Oroz et al. (1992) Immunol. Lett. 32, 7-12).

[011] VCAM-1 is expressed by cells in both a membrane-bound and soluble form. The soluble form has been shown to induce chemotaxis of vascular endothelial cells in vitro and to stimulate an angiogenic response in rat cornea (Koch et al. (1995) Nature 376, 517-519). Inhibitors of the expression of soluble VCAM-1 have potential therapeutic value in treating diseases with an angiogenic component, including tumor growth and metastasis (Folkman & Shing (1992) Biol. Chem. 10931-10934).

[012] Because cardiovascular and inflammatory diseases are currently a leading cause of death and disability in the developed world, there is a strong need to identify new methods and pharmaceutical agents for its treatment. Thus, there is a need to identify and manipulate synthetic compounds that can affect the expression of mediators of the inflammatory process, such as, for example, VCAM-1.

[013] Interleukin-6 (IL-6) is a 22-27-kDa secreted glycoprotein that exhibits growth stimulatory and pro-inflammatory activities. IL-6 has also been called interferon-2 (IFN-2), IL-1-inducible 26-kDa protein, hepatocyte-stimulating factor, cytotoxic T-cell differentiation factor, and B-cell stimulatory factor (Trikha et
al. (2003) Clin. Cancer Res. 9, 4653-4665). IL-6 was originally identified in monocytes / macrophages, fibroblasts, and endothelial cells.

[014] IL-6 is secreted by various cell types and exerts its activities by binding to a high-affinity receptor complex, consisting of two membrane glycoproteins, an 80-kDa component receptor that binds IL-6 with low affinity (IL-6R) and a signal-transducing component of 130 kDa (also known as gp130) that does not bind IL-6 itself, but is required for high-affinity binding of IL-6 by the complex. The IL-6R can be cleaved by a transmembrane metalloproteinase to yield a soluble IL-6R.

[016] Generally, it is known that IL-6 is abnormally produced in some inflammatory, autoimmune, and neoplastic diseases. It has been proposed that abnormal production of IL-6 is an aspect of the mechanisms of these diseases (Hirano et al. (1990) Immunol. Today, 11, 443-449; Sehgal (1990) Proc. Soc. Exp. Biol. Med. 195, 183-191; Grau (1990) Eur. Cytokine NeM, 203-210; Bauer et al.

[017] Interleukin-6 is secreted by many advanced cancers, such as hormone-independent prostate cancer, and is believed to be a growth factor for such cancers. Additionally, the secretion of IL-6 by cancer cells is believed to
cause cachexia, the wasting syndrome characteristic of advanced cancers. Thus, reducing the level of IL-6 would be useful in treating such cancers. IL-6 also plays a key role in B cell development. Autoimmune diseases with a significant antibody component, such as rheumatoid arthritis, could be treated by decreasing IL-6 levels. Disorders involving B cell proliferation, such as multiple myeloma and B cell lymphoma, could also be treated by reducing IL-6 activity. Additionally, IL-6 plays an important role in bone remodeling by promoting bone resorption. Reducing IL-6 activity would have the effect of reducing bone resorption and could be used to treat osteoporosis.

[018] Accordingly, there have been various attempts to reduce the levels of IL-6, which are believed to be associated with the pathogenic mechanisms of these various diseases and conditions. A steroid formulation has been used for suppressing the cytokines in the art, but such medicines may causes severe side-effects, such as peptic ulcers, if administered for an extended period.

[019] Anti-IL-6 antibodies have been shown to be effective in treating several diseases and disorders. For example, anti-IL-6 monoclonal antibodies have been shown to block the proliferation of myeloma cells both in vivo and in vitro (Rossi et al. (2005) Bone Marrow Transplantation 36, 771-779). Administration of anti-IL-6 antibodies to chronic rheumatoid arthritis patients was found to alleviate the symptoms of the disease (Wendling et al. (1993) J. Rheumatol. 20, 259-262). Anti-IL-6 antibodies have also been shown to be effective in treating AIDS-associated lymphoma (Emilie et al. (1994) Blood 84, 2472-2479), and metastatic renal cell carcinoma (Blay et al. (1997) Int. J. Cancer 72, 424-430). Clinical results involving the administration of anti-IL-6 antibodies to treat various other diseases and disorders are summarized in Trikha et al. (2003) Clin. Cancer Res. 9, 4653-4665.

[020] Thus, the present invention provides non-naturally occurring compounds that are useful for regulating the expression of interleukin-6 (IL-6) and vascular cell adhesion molecule-1 (VCAM-1), as well as the use of such compounds for the treatment and prevention of cardiovascular and inflammatory diseases, such as, for example, atherosclerosis, asthma, arthritis, cancer, multiple sclerosis, psoriasis, inflammatory bowel diseases, and autoimmune disease(s).
[021] Without wishing to be bound to theory, it is believed that the compounds of the invention act by inhibiting expression of IL-6 and/or VCAM-1 in the subject receiving the compound. However, regardless of the mechanism of action, administration of one or more compounds of the present invention will reduce the levels of IL-6 and/or VCAM-1 in the subject and as a result treat or reduce the incidence of cardiovascular and/or inflammatory diseases.

[022] One aspect of the invention provides a method for inhibiting the expression of, or reducing IL-6 and/or VCAM-1 in a subject comprising administering to the subject in need thereof, a therapeutically effective amount of at least one compound of Formula I:

Pharmaceutical Compositions

[0141] Pharmaceutical compositions of the invention comprise at least one compound of Formula I, II, III, IV, V, or tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof formulated together with one or more pharmaceutically acceptable carriers. These formulations include those suitable for oral, rectal, topical, buccal and parenteral (e.g., subcutaneous, intramuscular, intradermal, or intravenous) administration. The most suitable form of administration in any given case will depend on the degree and severity of the condition being treated and on the nature of the particular compound being used.

[0142] Formulations suitable for oral administration may be presented in discrete units, such as capsules, cachets, lozenges, or tablets, each containing a predetermined amount of a compound of the invention as powder or granules; as a solution or a suspension in an aqueous or non-aqueous liquid; or as an oil-in-water or water-in-oil emulsion. As indicated, such formulations may be prepared by any suitable method of pharmacy which includes the step of bringing into
association at least one compound of the invention as the active compound and a carrier or excipient (which may constitute one or more accessory ingredients). The carrier must be acceptable in the sense of being compatible with the other ingredients of the formulation and must not be deleterious to the recipient. The carrier may be a solid or a liquid, or both, and may be formulated with at least one compound described herein as the active compound in a unit-dose formulation, for example, a tablet, which may contain from about 0.05% to about 95% by weight of the at least one active compound. Other pharmacologically active substances may also be present including other compounds. The formulations of the invention may be prepared by any of the well known techniques of pharmacy consisting essentially of admixing the components.

[0143] For solid compositions, conventional nontoxic solid carriers include, for example, pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharin, talc, cellulose, glucose, sucrose, magnesium carbonate, and the like. Liquid pharmacologically administrable compositions can, for example, be prepared by, for example, dissolving or dispersing, at least one active compound of the invention as described herein and optional pharmaceutical adjuvants in an excipient, such as, for example, water, saline, aqueous dextrose, glycerol, ethanol, and the like, to thereby form a solution or suspension. In general, suitable formulations may be prepared by uniformly and intimately admixing the at least one active compound of the invention with a liquid or finely divided solid carrier, or both, and then, if necessary, shaping the product. For example, a tablet may be prepared by compressing or molding a powder or granules of at least one compound of the invention, which may be optionally combined with one or more accessory ingredients. Compressed tablets may be prepared by compressing, in a suitable machine, at least one compound of the invention in a free-flowing form, such as a powder or granules, which may be optionally mixed with a binder, lubricant, inert diluent and/or surface active/dispersing agent(s). Molded tablets may be made by molding, in a suitable machine, where the powdered form of at least one compound of the invention is moistened with an inert liquid diluent.

[0144] Formulations suitable for buccal (sub-lingual) administration include lozenges comprising at least one compound of the invention in a flavored base,
usually sucrose and acacia or tragacanth, and pastilles comprising the at least one compound in an inert base such as gelatin and glycerin or sucrose and acacia.

[0145] Formulations of the invention suitable for parenteral administration comprise sterile aqueous preparations of at least one compound of Formula I, II, III, IV, V, or tautomers, stereoisomers, pharmaceutically acceptable salts, and hydrates thereof, which are approximately isotonic with the blood of the intended recipient. These preparations are administered intravenously, although administration may also be effected by means of subcutaneous, intramuscular, or intradermal injection. Such preparations may conveniently be prepared by admixing at least one compound described herein with water and rendering the resulting solution sterile and isotonic with the blood. Injectable compositions according to the invention may contain from about 0.1 to about 5% w/w of the active compound.

[0146] Formulations suitable for rectal administration are presented as unit-dose suppositories. These may be prepared by admixing at least one compound as described herein with one or more conventional solid carriers, for example, cocoa butter, and then shaping the resulting mixture.

[0147] Formulations suitable for topical application to the skin may take the form of an ointment, cream, lotion, paste, gel, spray, aerosol, or oil. Carriers and excipients which may be used include Vaseline, lanoline, polyethylene glycols, alcohols, and combinations of two or more thereof. The active compound (i.e., at least one compound of Formula I, II, III, IV, V, or tautomers, stereoisomers, pharmaceutically acceptable salts, and hydrates thereof) is generally present at a concentration of from about 0.1% to about 15% w/w of the composition, for example, from about 0.5 to about 2%.

[0148] The amount of active compound administered may be dependent on the subject being treated, the subject's weight, the manner of administration and the judgment of the prescribing physician. For example, a dosing schedule may involve the daily or semi-daily administration of the encapsulated compound at a perceived dosage of about 1 μg to about 1000 mg. In another embodiment, intermittent administration, such as on a monthly or yearly basis, of a dose of the
encapsulated compound may be employed. Encapsulation facilitates access to the site of action and allows the administration of the active ingredients simultaneously, in theory producing a synergistic effect. In accordance with standard dosing regimens, physicians will readily determine optimum dosages and will be able to readily modify administration to achieve such dosages.

[0149] A therapeutically effective amount of a compound or composition disclosed herein can be measured by the therapeutic effectiveness of the compound. The dosages, however, may be varied depending upon the requirements of the patient, the severity of the condition being treated, and the compound being used. In one embodiment, the therapeutically effective amount of a disclosed compound is sufficient to establish a maximal plasma concentration. Preliminary doses as, for example, determined according to animal tests, and the scaling of dosages for human administration is performed according to art-accepted practices.

[0150] Toxicity and therapeutic efficacy can be determined by standard pharmaceutical procedures in cell cultures or experimental animals, e.g., for determining the LD$_{50}$ (the dose lethal to 50% of the population) and the ED$_{50}$ (the dose therapeutically effective in 50% of the population). The dose ratio between toxic and therapeutic effects is the therapeutic index and it can be expressed as the ratio LD$_{50}$/ED$_{50}$. Compositions that exhibit large therapeutic indices are preferable.

[0151] Data obtained from the cell culture assays or animal studies can be used in formulating a range of dosage for use in humans. Therapeutically effective dosages achieved in one animal model may be converted for use in another animal, including humans, using conversion factors known in the art (see, e.g., Freireich et al., Cancer Chemother. Reports 50(4):219-244 (1966) and Table 1 for Equivalent Surface Area Dosage Factors).

The dosage of such compounds lies preferably within a range of circulating concentrations that include the ED\textsubscript{50} with little or no toxicity. The dosage may vary within this range depending upon the dosage form employed and the route of administration utilized. Generally, a therapeutically effective amount may vary with the subject's age, condition, and gender, as well as the severity of the medical condition in the subject. The dosage may be determined by a physician and adjusted, as necessary, to suit observed effects of the treatment.

In one embodiment, a compound of Formula I, II, III, IV, V or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof, is administered in combination with another therapeutic agent. The other therapeutic agent can provide additive or synergistic value relative to the administration of a compound of the invention alone. The therapeutic agent can be, for example, a statin; a PPAR agonist, e.g., a thiazolidinedione or fibrate; a niacin, a RVX, FXR or LXR agonist; a bile-acid reuptake inhibitor; a cholesterol absorption inhibitor; a cholesterol synthesis inhibitor; a cholesteryl ester transfer protein (CETP), an ion-exchange resin; an antioxidant; an inhibitor of AcylCoA cholesterol acyltransferase (ACAT inhibitor); a tyrophostine; a sulfonylurea-based drug; a biguanide; an alpha-glucosidase inhibitor; an apolipoprotein E regulator; a HMG-CoA reductase inhibitor, a microsomal triglyceride transfer protein; an LDL-lowering drug; an HDL-raising drug; an HDL enhancer; a regulator of the apolipoprotein A-IV and/or apolipoprotein genes; or any cardiovascular drug.

In another embodiment, a compound of Formula I, II, III, IV, V or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof, is administered in combination with one or more anti-inflammatory agents. Anti-inflammatory agents can include immunosuppressants, TNF inhibitors, corticosteroids, non-steroidal anti-inflammatory drugs (NSAIDs), disease-
modifying anti-rheumatic drugs (DMARDS), and the like. Exemplary anti-inflammatory agents include, for example, prednisone; methylprednisolone (Medrol®), triamcinolone, methotrexate (Rheumatrex®, Trexall®), hydroxychloroquine (Plaquenil®), sulfasalazine (Azulfidine®), leflunomide (Arava®), etanercept (Enbrel®), infliximab (Remicade®), adalimumab (Humira®), rituximab (Rituxan®), abatacept (Orencia®), interleukin-1, anakinra (Kineret™), ibuprofen, ketoprofen, fenoprofen, naproxen, aspirin, acetaminophen, indomethacin, sulindac, meloxicam, piroxicam, tenoxicam, lornoxicam, ketorolac, etodolac, mephenamic acid, meclofenamic acid, flufenamic acid, tolfenamic acid, diclofenac, oxaprozin, apazone, nimesulide, nabumetone, tenidap, etanercept, tolmetin, phenylbutazone, oxyphenbutazone, diflunisal, salsalate, olsalazine or sulfasalazine.

**Therapeutic Methods**

[0155] In one embodiment, a method of treating or preventing cardiovascular and inflammatory diseases and related disease states, characterized by altered expression of markers of inflammation such as IL-6 and/or VCAM-1 proliferation, comprises administering to a subject (e.g., a mammal, such as e.g., a human) a therapeutically effective amount of at least one compound of the invention, i.e., a compound of Formula I, II, III, IV, V, or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof. In another embodiment, at least one compound of the invention may be administered as a pharmaceutically acceptable composition, comprising one or more compounds of the invention and a pharmaceutically acceptable carrier.

[0156] In one embodiment, the inflammatory diseases and related disease states are those where inhibition of IL-6 and/or VCAM-1 proliferation is desirable.

[0157] In some embodiments, the methods of the invention comprise administering at least one compound of the invention to a subject, such as a human, as a preventative measure against cardiovascular and inflammatory diseases and related disease states, such as, for example, atherosclerosis, asthma, arthritis, cancer, multiple sclerosis, psoriasis, and inflammatory bowel diseases, and autoimmune disease(s).
In one embodiment, at least one compound of the invention is administered as a preventative measure to a subject, such as a human, having a genetic predisposition to cardiovascular and inflammatory diseases and related disease states, such as, for example, familial hypercholesterolemia, familial combined hyperlipidemia, atherosclerosis, a dyslipidemia, a dyslipoproteinemia, arthritis, cancer, multiple sclerosis, or Alzheimer's disease.

In another embodiment, at least one compound of the present invention is administered as a preventative measure to a subject, such as a human, having a non-genetic predisposition to a disease including a cardiovascular disease or an inflammatory disorder. Examples of such non-genetic predispositions include cardiac bypass surgery and PTCA (which can lead to restenosis), an accelerated form of atherosclerosis, diabetes in women, (which can lead to polycystic ovarian disease), and cardiovascular disease (which can lead to impotence). Accordingly, compositions of the invention may be used for the prevention of one disease or disorder and concurrently treating another (e.g., prevention of polycystic ovarian disease while treating diabetes; prevention of impotence while treating cardiovascular disease).

Angioplasty and open heart surgery, such as coronary bypass surgery, may be required to treat cardiovascular diseases, such as atherosclerosis. These surgical procedures entail using invasive surgical devices and/or implants, and are associated with a high risk of restenosis and thrombosis. Accordingly, the compounds of the invention may be used as coatings on surgical devices (e.g., catheters) and implants (e.g., stents) to reduce the risk of restenosis and thrombosis associated with invasive procedures used in the treatment of cardiovascular diseases.

In another embodiment, the compounds of the invention may be used for the prevention of one disease or disorder while concurrently treating another (e.g., prevention of polycystic ovarian disease while treating diabetes; prevention of impotence while treating a cardiovascular disease).

Example 127. Quantification of hiL-6 mRNA

[0472] In this example, hiL-6 mRNA in tissue culture cells was quantitated to measure the transcriptional inhibition of hiL-6 when treated with a compound of the invention.

[0473] A human leukemic monocyte lymphoma cell line (U937) was plated (3.2 $\times$ 10$^5$ cells per well) in a 96-well plate in 100 µL RPMI-1640, and differentiated for 3 days prior to the addition of the compound of interest. The cells were pretreated for 1 h with the test compound prior to stimulation with lipopolysaccharide from Escherichia coli. The cells were incubated at 37°C for 3 h before the cells were harvested. At time of harvest, the spent media was removed from the cells and the cells were rinsed in 200 µL PBS. Cell lysis solution (70 µL) was added to the cells in each well and incubated for 5-10 min at room temperature, to allow for complete cell lysis and detachment. mRNA was then prepared using the "mRNA Catcher PLUS plate" (Invitrogen), according to the protocol supplied. After the last wash, as much wash buffer as possible was aspirated without allowing the wells to dry. Elution buffer (E3, 70 µL) was then added to each well. mRNA was then eluted by incubating the mRNA Catcher PLUS plate with Elution Buffer for 5 min at 68°C and then immediately placing the plate on ice.

[0474] The eluted mRNA isolated was then used in a one-step quantitative real-time PCR reaction, using components of the Ultra Sense Kit together with Applied Biosystems primer-probe mixes. Real-time PCR data was analyzed,
normalizing the Ct values for hIL-6 to an internal control, prior to determining the fold induction of each unknown sample, relative to the control.

[0475] In Table 2, an active compound is one that causes a ≥ 20% inhibition in IL-6 mRNA at a concentration less than or equal to 10 µM.

Example 128. Quantification of hVCAM mRNA

[0476] In this example, hIL-6 mRNA in tissue culture cells was quantitated to measure the transcriptional inhibition of hVCAM when treated with a compound of the invention.

[0477] Human umbilical vein endothelial cells (HUVECs) were plated in a 96-well plate (4.0x10^3 cells/well) in 100 μL EGM media and incubated for 24 h prior to the addition of the compound of interest. The cells were pretreated for 1 h with the test compound prior to stimulation with tumor necrosis factor-α. The cells were incubated for an additional 24 h before the cells were harvested. At time of harvest, the spent media was removed from the HUVECs and rinsed in 200 μL PBS. Cell lysis solution (70 μL) was then added the cells in each well and incubated for ~5-10 min at room temperature, to allow for complete cell lysis and detachment. mRNA was then prepared using the "mRNA Catcher PLUS plate" (Invitrogen), according to the protocol supplied. After the last wash, as much wash buffer as possible was aspirated without allowing the wells to dry. Elution buffer (E3, 70 μL) was then added to each well. mRNA was then eluted by incubating the mRNA Catcher PLUS plate with elution buffer for 5 min at 68°C and then immediately placing the plate on ice.

[0478] The eluted mRNA so isolated was then used in a one-step quantitative real-time PCR reaction, using components of the Ultra Sense Kit together with Applied Biosystems primer-probe mixes. Real-time PCR data was analyzed, normalizing the Ct values for hVCAM to an internal control, prior to determining the fold induction of each unknown sample, relative to the control.
In Table 3, an active compound is one that causes a \( \geq 20\% \) inhibition in VCAM-1 mRNA at a concentration less than or equal to 10 \( \mu \text{M} \).
