## CHOLANE DERIVATIVES FOR USE IN THE TREATMENT AND/OR PREVENTION OF FXR AND TGR5/GPBAR1 MEDIATED DISEASES

### FIELD OF THE INVENTION

5 The present invention relates to compounds having cholane scaffolds, said compounds for use in the treatment and/or prevention of FXR and TGR5/GPBAR1 mediated diseases.

### STATE OF THE ART

Bile acids (BAs) are signaling molecules interacting with two type of dedicated

10 cellular receptors, intracellular nuclear receptors and cell-surface receptors. Nuclear receptors include farnesoid X receptor (FXR), identified as the endogenous bile acid sensor (Makishima et al *Science* 1999, 284, 1362; Parks et al. *Science* 1999, 284, 1365).

Highly expressed in entero-hepatic tissues (liver and intestine), FXR regulates bile

15 acid homeostasis, metabolic pathways also including lipid and glucose homeostasis (Zhang et al. *Proc. Natl. Acad. Sci. USA* 2006, 103, 1006). Additionally FXR agonists provides anti-inflammatory and anti-fibrotic and anticancer effects (Renga et al. *FASEB J.* 2012, 26, 3021-3031).

Bile acid cell-surface receptor (GPBAR1, M-BAR1, GP-BAR1, TGR5) belongs to the

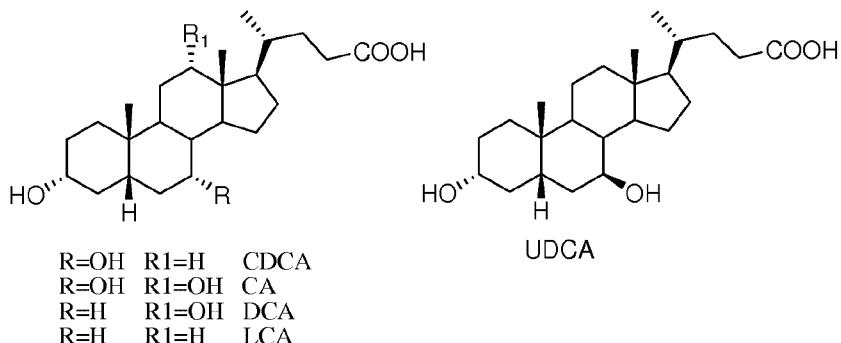

20 rhodopsin-like superfamily of G protein coupled receptors (Takeda et al. *FEBS Lett.* 2002, 520, 97; Kawamata et al. *J. Biol. Chem.* 2003, 278, 9435).

Ligand binding to TGR5/GPBAR1 results in elevation of intracellular cAMP levels

with consequently activation of a signaling cascade. GPBAR1 is highly expressed

in the liver and in the intestine but also muscles, brain, adipose tissue, macrophages

25 and endothelial cells. In muscle and brown adipose tissue, TGR5/GPBAR1 increases energy expenditure and oxygen consumption (Watanabe et al. *Nature* 2006, 439, 484) in entero-endocrine L cells, TGR5/GPBAR1 activation stimulates the secretion of glucagon-like peptide (GLP)-1, an incretin that improves pancreas insulin release, thus regulating glucose blood levels, gastrointestinal motility and appetite (Thomas, et al. *Cell. Metab.* 2009, 10, 167).

Chemically BAs are truncated cholesterol side chain derivatives. Their molecular repertoire is generated firstly in the liver with the production of primary bile acids, cholic acid (CA) and chenodeoxycholic acid (CDCA). Microbio-transformation in the intestine generates secondary bile acids, deoxycholic acid (DCA) and lithocholic acid (LCA), In human body bile acids are conjugated to glycine and taurine. The activity towards the two BA receptors is structure dependent with CDCA the most potent endogenous FXR activator, and LCA and TLCA the strongest natural agonists of TGR5/GPBAR1.

Cholestatic pruritus has been noted as a severe side-effect associated with the use of FXR agonists in PBC and a recent study indicated TGR5/GPBAR1 as the molecular target involved in the development of this side effect (Alemi et al. *J. Clin. Invest.* 2013, 123, 1513–1530).

WO2013192097 describes 6-alpha-ethyl-chenodeoxycholic acid (6-ECDCA), a potent and selective FXR agonist endowed with anticholestatic effect.

WO2008002573 describes bile acid derivatives as FXR ligands for the prevention or treatment of FXR-mediated diseases or conditions.

WO2010014836 and Sato H. (*J. Med. Chem.* 2008, 51, 4849) describes TGR5 modulators.

D'Amore C. et al. (*J. Med. Chem.* 2014, 57, 937) describes Design, synthesis, and biological evaluation of GP-BAR1/FXR dual agonists. D'Amore et al. describes compounds BAR502 and BAR504 as synthesis intermediates.

Iguchi Y. et al. (*J. Lipid Res.* 2010, 51, 1432) describes bile alcohols function as the ligands of TGR5.

Compounds BAR107 is disclosed as synthesis intermediate by Kihira K. et al. (Steroids 1992, 57(4), 193-198).

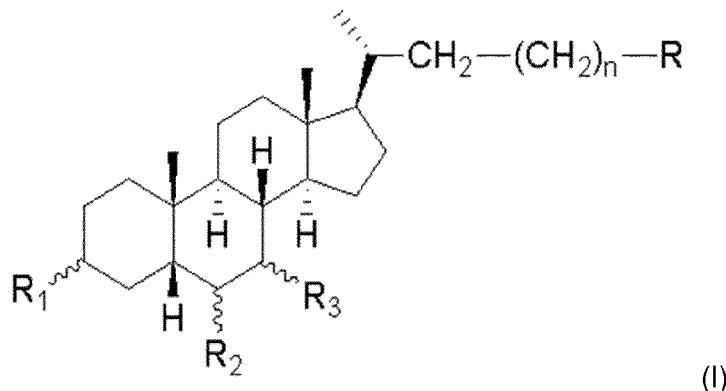

Swaan P. W. et al. (J. Comp.-Aid. Mol. Des. 1997, 11, 581-588) in a molecular modeling of the intestinal bile acid carrier tested ursodeoxycholate (therein compound 15, herein BARn406) among a set of bile acid-conjugates. BARn406 resulted to have an undetectable ability to inhibit taurocholic acid transport in CaCo-2 cells.

5 Burns et al. (Steroids 2011, 76(3), 291-300) describes synthesis and olfactory activity of unnatural, sulfated 5-bile acid derivatives in the sea lamprey (*Petromyzon marinus*). Therein disclosed compound 9e (herein compound BAR407) did not elicit an olfactory response.

Aim of the present invention is the identification of novel compounds containing the 10 cholane chemical scaffold and that modulate FXR and/or TGR5/GPBAR1.

For one aspect, the present invention relates to compounds of formula (I) wherein the compounds are FXR and TGR5/GPBAR1 dual agonists. A selected example in this group is BAR502. Surprisingly, BAR502 does not induce itching when administered to animals rendered cholestatic by administration of ANIT or Estrogen. In cholestatic syndromes, body accumulation of bile acids is thought to cause itching. Recently, TGR5/GPBAR1 shown to mediate itching caused by intradermal administration of DCA and LCA (Alemi et al. J. Clin. Invest. 2013, 123, 1513–1530). In clinical trials, administration of patients suffering from primary biliary cirrhosis (PBC) with obeticholic acid has resulted in severe itching in approximately 80% of patients. One specific and surprising advantage of BAR502 is that this agent do not induce itching when administered to animals rendered cholestatic by administration of  $\alpha$ -naphthyl-isothiocyanate (ANIT) or  $17\alpha$ -ethynodiol (two validated model of cholestasis). In these experimental setting BAR502 administration increases survival, attenuates serum alkaline phosphatase levels and robustly modulates the

liver expression of canonical FXR target genes including OSTα, BSEP, SHP and MDR1, without inducing pruritus. In the 17 $\alpha$ -ethynylestradiol model, BAR502 attenuates cholestasis and reshapes bile acid pool without inducing itching, demonstrating that in models of non-obstructive cholestasis, BAR502 attenuates 5 liver injury without causing itching.

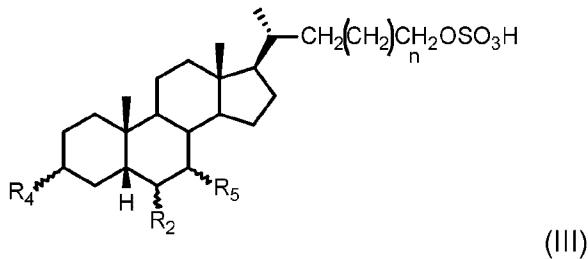

In one aspect, the present invention relates to compounds of formula (I) wherein the compounds are high selective FXR agonists without effects on GPBAR1 when administered alone but effective in inhibiting GPBAR1 activation caused by TLCA (10  $\mu$ M), thus behaving as GPBAR1 antagonists. 15 **Biological Activities.** Activity of selected compounds was tested in vitro using a whole cell model transfected with a reporter genes to establish selectivity of compounds shown in table 1 toward FXR and TGR5/GPBAR1 in comparison with chenodeoxycholic acid (CDCA) and TLCA. CDCA is a primary bile acid that functions as an endogenous ligand for FXR, while TLCA is a physiological ligand for

20 TGR5/GPBAR1. In this assay, HepG2 cells (a liver-derived cell line) were cultured at 37 °C in minimum essential medium with Earl's salts containing 10% fetal bovine serum (FBS), 1% L-glutamine, and 1% penicillin/streptomycin. HEK-293T cells were cultured at 37 °C in D-MEM containing 10% fetal bovine serum (FBS), 1% L-glutamine, and 1% penicillin/streptomycin. The transfection experiments were

25 performed using Fugene HD according to manufactured specifications. Cells were plated in a 24-well plate at 5 × 10<sup>4</sup> cells/well. For FXR mediated transactivation, HepG2 cells were transfected with 100 ng of pSG5-FXR, 100 ng of pSG5-RXR, 100 ng of pGL4.70 a vector encoding the human Renilla gene and 250 ng of the reporter vector p(hsp27)-TK-LUC containing the FXR response element IR1 cloned from the promoter of heat shock protein 27 (hsp27).

30 For GPBAR1 mediated transactivation, HEK-293T cells were transfected with 200 ng of pGL4.29, a reporter vector containing a cAMP response element (CRE) that

drives the transcription of the luciferase reporter gene luc2P, with 100 ng of pCMVSPORT6-human GPBAR1, and with 100 ng of pGL4.70 a vector encoding the human Renilla gene. In control experiments HEK-293T cells were transfected only with vectors pGL4.29 and pGL4.70 to exclude any possibility that compounds could 5 activate the CRE in a GPBAR1 independent manner. At 24 h post-transfection, cells were stimulated for 18 h with 10 µM TLCA as a control agent or putative GPBAR1 agonists as the same concentration. After treatments, cells were lysed in 100 µL of lysis buffer (25 mM Tris-phosphate, pH 7.8; 2 mM DTT; 10% glycerol; 1% Triton X-100), and 20 µL of cellular lysate was assayed for luciferase activity using the 10 luciferase assay system. Luminescence was measured using Glomax 20/20 luminometer. Luciferase activities were normalized against Renilla activities. Antagonism against FXR of GPBAR1/TGR5 was measured as percent of activity in transactivation assay suing activity of TLCA as example of agonism.

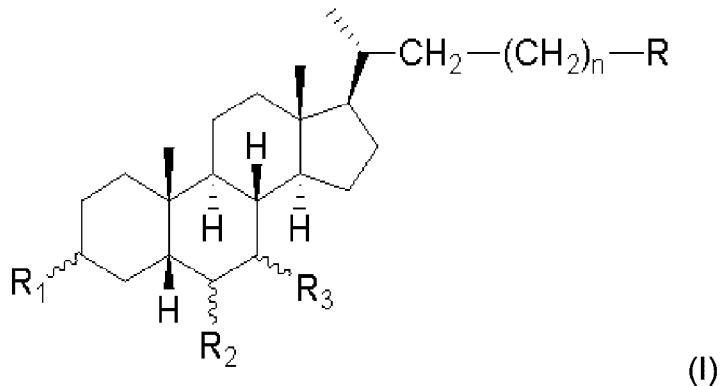

**Animals and protocols.** GPBAR1 null mice (GPBAR1-B6=GPBAR12/2 mice, 15 generated directly into C57BL/6NCrl background), and congenic littermates on C57BL/6NCrl were housed under controlled temperatures (22 °C) and photoperiods (12:12-hour light/dark cycle), allowed unrestricted access to standard mouse chow and tap water and allowed to acclimate to these conditions for at least 5 days before inclusion in an experiment.

**20 Scratching test.** Male GPBAR1<sup>-/-</sup> mice and their congenic littermates (8–12 weeks of age) were used for this studies. The fur at the base of the neck was shaved, and mice were placed in individual cylinders on a glass shelf. A circumference of approx. 0.5 cm of diameter was drawn in the neck and test agents injected in this area. Mice were acclimatized to the experimental room, restraint apparatus and investigators 25 for 2 h periods on 2 successive days before experiments. Scratching behavior was quantified by 2 observers unaware of tested agents or genotypes. A scratch was defined as lifting the hind limb to the injection site and then a placing of the paw on the floor, regardless of the number of strokes. If counts differed by greater than 5 scratches over a 30-minute period, both observers reevaluated the records. Results 30 were expressed as the number of scratching events during 30 or 60 min of observation. Tested agents were: DCA (25 µg), TLCA (25 µg), UDCA (25 µg), and BAR502 (25 µg), or with betulinic acid (50 µg), oleanolic acid (50 µg). LCA and DCA

were dissolved in DMSO and the other agents in 0.9% NaCl (10  $\mu$ L). In another experimental setting GPBAR1 $^{-/-}$  mice and their congenic littermates were administered alpha-naphthylisothiocyanate (ANIT) (25 mg/kg, *per os*) dissolved in olive oil or olive oil alone (control mice) or with the combination of ANIT plus BAR502 (15 mg/Kg once a day, *per os*) for 10 days. At day 5 spontaneous scratching was evaluated for 60 min and after subcutaneous injection of 25  $\mu$ g DCA. Serum levels of total bilirubin, aspartate aminotransferase (AST) and alkaline phosphatase were measured by routine clinical chemistry testing performed on a Hitachi 717 automatic analyzer. For the estrogen model, wild type C57BL6 mice were administered 10 mg/Kg i.p. with 17 $\alpha$ -Ethynylestradiol (17 $\alpha$ E<sub>2</sub>) dissolved in PEG or PEG alone (control mice) or the combination of 17 $\alpha$ E<sub>2</sub> and BAR502 (15 mg/Kg daily, *per os*) for 8 days. At the end of the study the spontaneous scratching and scratching induced by s.c. injection of 25  $\mu$ g DCA was recorded. Gallbladder weight and serum levels of bilirubin and alkaline phosphatase were also measured. Throughout the studies animals were visually assessed at least twice a day from Monday to Friday and once a day over the week end by investigators and by highly trained animal facility personnel's including animal facility's veterinarian. Animals were weighted daily and sacrificed at indicated time points or when their clinical conditions become critical as assessed by a reduction of body weight higher than 25% of basal body weight in 7 days. In addition, animals were sacrificed when at the daily evaluation they demonstrate inability to rise or ambulate. Mice were euthanized by an overdose of sodium pentobarbital (>100 mg/kg i.p.).
