Title: MEDICATION DELIVERY SYSTEM

Abstract: A medication delivery system (20) having features of the present invention comprises a medical container (26) holding a prescribed medication (27) to be delivered to a patient, a tag 24 adapted to be worn by the patient, a handheld computing device (22), and an electronic medication delivery device (30). Data on the medication (27) is contained in a first label (28) on the medication container (27). The first label (28) also contains the instruction on how the medication is delivered to the patient, including the appropriate settings for an electronic medication delivery device for delivering the medication to the patient. Patient data is contained in a second label (29) on the tag (24) worn by the patient. The medication data, medication delivery instruction, and patient data are provided in machine readable formats. The handheld computing device (22) reads the medication data and the medication delivery instruction on the medication container (26) and the patient data on the patient tag (24). The handheld computing device (22) stores the information obtained and performs a matching check to confirm that the medication data matches with the patient data. Upon a confirmed match, it transmits the medication delivery instruction to the electronic medication delivery device (30), which downloads the instruction, programs the delivery device 30, and prompts an operator to begin delivering the medication (27) to the patient according to the downloaded instruction.
MEDICATION DELIVERY SYSTEM

DESCRIPTION

Technical Field

The present invention is directed to a medication delivery system and in particular, a medication delivery system that reduces potential medication errors by delivering the right dose to the right patient with the right drug at the right time and by the right route.

Background of the Invention

According to a 1999 Institute of Medicine Report, human error contributes to approximately 70,000-100,000 deaths per year caused by "medical errors." As a designation, medical errors are associated with a multitude of circumstances and causes. However, studies show that a significant percentage of serious errors are associated with the administration of intravenous (IV) medication.

A patient’s response to drugs delivered intravenously is rapid because the gastrointestinal system is bypassed. Thus, if an error is made, there is little time to compensate. Most critical drugs are delivered intravenously. Correct administration is a process that often involves several individuals for delivering an accurate dose of a drug to a particular patient at a prescribed time and through a particular administration route. It is not difficult to comprehend the potential for error, as well as the undesirable probability that the occurrence of an error can result in one or more detrimental effects to the patient.

An intravenous error may be induced at any time throughout the process of ordering, transcribing, dispensing, and administering a drug. For example, an ordering error may occur because an order is illegible, incomplete, or entered on the wrong patient’s chart, because a decimal is misplaced or inappropriate, or unacceptable prescription abbreviations are used, or because an inappropriate drug is selected or a patient’s allergies are not properly identified. Transcription errors may occur because an order was not transcribed, not completely signed off, or incorrectly transcribed onto the Medication Administration Record (MAR). Also, on occasion a patient’s allergies are not transcribed or a transcription is illegible. Dispensing errors may occur with respect to the dose, or the identification of the medication or patient. An administration error may occur at any time during the course of a patient’s care and may
concern the patient or drug identification, or the time, dose, or route of drug administration. It is notable that research indicates that 60-80% of intravenous errors are attributed to humans. It follows then that one way to reduce the potential for error is to automate as much as possible the process of drug ordering, transcribing, dispensing, and administering.

Information technology may be utilized for automating portions of the drug ordering, transcribing, dispensing, and administration process. For example, the potential for error may be reduced by cross referencing infusion data used to program a pump and also by reviewing data programmed into a pump prior to enabling the pump to operate and also by detecting if programmed data is changed.

One system for collecting data and managing patient care is disclosed in U.S. Patent No. 5,781,442 issued to Engleson et al. The system may include a pharmacy computer, a nursing station computer, and bedside computers that may be connected to clinical devices such as infusion pumps. The various computers are connected together via a local area network. The computers have memory for storing certain information relating to a patient’s care and information can be inputted into the computers. The pharmacy computer will compare information communicated from the bedside computer to information stored in the pharmacy computer. If the comparison satisfies a predetermined condition, the pharmacy computer downloads clinical device operating parameters to the bedside computer. The bedside computer, in turn, programs the clinical device to operate in accordance with the downloaded operating parameters. The comparison of data is only performed by the pharmacy computer. This system requires several computers as a computer is required at each bedside in order to program the clinical device.

Another system for automatically entering into an infusion pump patient identification and drug data is disclosed in U.S. Patent 5,317,506 (Coutré et al.), entitled “Infusion Fluid Management System.” The ‘506 patent is directed at a pharmacy management system and an infusion pumping system in combination for managing and analyzing prescribed infusion programs. In this system, patient and IV container information is provided in machine readable format. This information is read by a bar code reader attached to the pump. The pump has a processor that is programmed to compare the patient information to the IV container information. This system requires, therefore, that each pump be programmed (or reprogrammed) to compare the patient data to medication data. Also, if an allergy check is
desired, the pump must also be programmed with a patient’s allergies. Other encumbrances to such a system stem from the requirement that the pump must be able to read the patient code and the IV container code. Because pumps are mobilized frequently, disconnecting them from power and wired data communication, as well as programming the pumps with prescription data and verifying the prescription data in a mobile environment is important. The physical location of the patient code (which is usually attached to the patient) and IV container code in relation to the pump is an important, and potentially limiting, consideration. Also, changes made to data formats, such as from 1-dimensional bar code to 2-dimensional bar code, must be reprogrammed into each pump, as well as patient allergies and any other data that is or may be desirable for administering patient therapy. Further, the system of the ‘506 patent does not provide for an ancillary check on the pump programming data and operational instructions. Information is input into the pump without any prior check for accuracy or completeness and there is no separate system in place for reviewing programmed and operational information to ensure that it is not inaccurate, imprecise, and/or improper.

Accordingly, a need remains for a system that provides a check on patient and pump data prior to pump programming, automatically transmits checked infusion data to the pump, is easily configurable, reconfigurable, and mobile in application, and can verify and check that data programmed into the pump and pump operational data remain correct and unchanged.

The present invention is provided to solve these and other problems.

Summary of the Invention

The present invention is directed to a medication delivery system, in particular, a medication delivery system that reduces potential medication errors by delivering the right dose to the right patient with the right drug at the right time and by the right route. The system can also be configured for solely monitoring.

A medication delivery system having features of the present invention comprises a medical container holding a prescribed medication to be delivered to a patient, a tag adapted to be worn by the patient, a handheld computing device, and an electronic medication delivery device. Data on the medication is contained in a first label on the medication container. The first label also contains the instruction on how the medication is delivered to the patient, including the appropriate settings for an electronic medication delivery device for delivering the
medication to the patient. Patient data is contained in a second label on the tag worn by the patient. The medication data, medication delivery instruction, and patient data are provided in machine readable formats. The handheld computing device reads the medication data and the medication delivery instruction on the medication container and the patient data on the patient tag. The handheld computing device stores the information obtained and performs a matching check to confirm that the medication data matches with the patient data. Upon a confirmed match, it transmits the medication delivery instruction to the electronic medication delivery device, which downloads the instruction, programs the delivery device, and prompts an operator to begin delivering the medication to the patient according to the downloaded instruction. In an alternative form of the invention, the medication delivery device can be a general medical device such as a device for monitoring data.

In a preferred embodiment of the present invention, the medication container is an IV bag, the prescribed medication is an IV drug, the patient tag is a bracelet worn by the patient, the handheld computing device is a personal digital assistant (PDA), and the electronic medication delivery device is a programmable infusion pump. The medication data, medication delivery instruction, and the patient data are provided as two-dimensional bar codes to be read by a bar code scanner incorporated into the personal digital assistant. The communication between the personal digital assistant to the electronic infusion pump is via infrared transmission. The programmable pump may further comprise an adapter which facilitates the communication between the PDA and the infusion pump, and reviews data programmed into the pump and pump operational parameters.

The system of the present invention may also be configured to deliver multiple medications.

The present invention is also directed to a method of medication delivery to reduce medication errors according to the features disclosed in the invention.

Other features and advantages of the invention will become apparent from the following description taken in conjunction with the following drawings.

**Brief Description of the Drawings**

FIG. 1 is a schematic view disclosing functional relationships between components of one embodiment of the present invention;
FIGS. 2-34 are examples of displays provided on a computing device in accord with one embodiment of the present invention;

FIG. 35 is a flow chart showing several steps for scanning a single medication;

FIGS. 36(a) - 36(c) are flow charts showing several steps for scanning two medications;

and

FIGS. 37-39 are additional examples of displays provided on a computing device in accord with one embodiment of the present invention.

**Detailed Description**

While this invention is susceptible of embodiments in many different forms, there is shown in the drawings and will herein be described in detail a preferred embodiment of the invention with the understanding that the present disclosure is to be considered as an exemplification of the principles of the invention and is not intended to limit the broad aspect of the invention to the embodiments illustrated.

Referring to the drawings, FIG. 1 shows a schematic view disclosing functional relationships between components of one embodiment of the present invention. A medication delivery system is generally disclosed and referred to with the reference numeral 20. The medication delivery system 20 generally comprises a medication container 26, a tag 24 adapted to be worn by a patient, a handheld computing device 22, and a medical device 30, which in one preferred embodiment, is a medication delivery device 30. The medication delivery system 20 can be configured to deliver medication in several different arrangements including parenteral and intravenous (e.g., non-oral) delivery.

The medication container 26 holds a prescribed medication 27. Information regarding the medication, which includes data on the medication and the specific instruction of delivering the medication to the patient is contained in a first label 28 on the medication container 26. The information is provided in machine readable format. Patient data is contained in a second label 29 on the tag 24 which is worn by the patient. This is typically in the form of a patient identification bracelet.

The handheld computing device 22 reads the medication data, medication delivery instruction, and patient data through a first information input device 36 integrated into the handheld computing device 22. The handheld computing device 22 stores the information and
performs a matching check to confirm that the medication data match with the patient data, and that the medication is intended for the patient as prescribed. If the matching is confirmed, the handheld computing device 22 prompts the operator to manually confirm the match and to transmit and download the medication delivery instruction, via a first communication device 32, to the electronic medication delivery device 30, which receives the information by a second communication device 38 integrated with or connected to the medication delivery device 30. The medication delivery device 30 then prompts the operator to start delivering the medication 27 according to the instruction downloaded from the handheld computing device 22. The medication 27 is delivered to the patient via a catheter 37. The catheter 37 contains a label 39 to uniquely identify the catheter 37. The label 39 of the catheter 37, preferably a bar code label, also contains information regarding the catheter such as the type of catheter (e.g. central venous catheter, peripheral catheter, or epidural catheter).

The prescribed medication 27 in the present invention is typically a fluid, which includes both liquid formulations and gases. A preferred liquid formulation is an intravenous parenteral formulation. Examples of other parenteral liquid formulations suitable in the present invention are intrathecal, epidural, intra-arterial and the like. Examples of gas medications include the inhaled anesthetic gases such as sevoflurane, halothane, and enflurane. More than one medication may be delivered at the same time with the system 20. If more than one medication is being delivered, the medications may be held in the same container or separate containers. In intravenous infusions, it is common that additional medication(s) may be delivered as a piggyback. When multiple containers are used, each container is connected to a separate pump channel 33 on the delivery pump 30. Each pump channel 33 contains a label 31 with information to uniquely identify the channel. The label 31 for the pump channel 33 is preferably a bar code label. The handheld device will communicate the information read from the channel label 31 to the pump 30 so that the appropriate channel is activated. Alternatively, each pump channel 33 also has its own second communication device 38 to receive information from the handheld computing device 22. Any information to be downloaded to a particular pump channel 33 from the handheld device 22 has to match with the unique pump channel identification so that only the appropriate information is downloaded to the correct pump channel 33.
The medication container 26 in the present invention depends on the prescribed medication 27. Each medication has its own requirements on the specific container in which it is packaged. Examples of the container 26 include but are not limited to flexible plastic IV bags, plastic bottles, glass bottles, plastic syringes, glass syringes, and glass vials, and elastomeric devices.

Information regarding the prescribed medication 27 is contained in the first label 28 on the medication container 26. The first label 28 is preferably generated by the pharmacist preparing the medication who also attaches the first label 28 onto the medication container 26. Alternatively, the first label 28 can be generated by a drug manufacturer, such as the National Data Corporation (NDC) in the form of a NDC label. The information includes data on the medication 27 and instruction on how the medication 27 is to be delivered by the medication delivery device 30. The medication data may include but is not limited to: patient name, patient identification number, physician name, order number, date, drug name, drug amount, diluent amount, and route of administration. The delivery instruction which is to be transmitted and downloaded to the medication delivery device 30 may include but is not limited to: delivery rate, delivery volume, dose, dose time, duration of delivery, and duration of therapy. For an IV infusion pump, the medication delivery instruction may further include: primary rate, primary volume-to-be-infused (VTBI), piggyback VTBI, piggyback rate or time, primary dose mode, and pump channel identification. Optional text information may also be included in the first label 28, such as: patient name, patient identification number, physician name, drug name, diluent name, cautions, expiry, delivery time, location, prepared date, prepared time, and preparer identification. The pharmacy that generates the first label preferably includes a pharmacy information system (not shown) having a printer port. In one embodiment, the printer is connected directly to the printer port. In this configuration, the pharmacy information system may also be set-up to generate a print stream that will print a text label that may contain the medication data and delivery instruction. In one embodiment, the bar code label may be generated with the data derived from the generated print stream wherein the data is encoded onto the bar code label. This can be accomplished using a separate software application. In an alternate embodiment, the pharmacy information is configured to also communicate the actual medication information to the handheld computing device 22.
Patient data is contained in the second label 29 on the patient tag 24 adapted to be worn by the patient. The patient tag 24 is worn by the patient before the administration of the medication 27. In a preferred embodiment, the tag 24 is a bracelet to be worn by the patient on the wrist. The second label 29 is preferably generated by a hospital administrator based upon information in the hospital administration database. Patient data may include but is not limited to: patient name, patient identification number, and allergies. Optional text information may also be included in the second label 29, such as: patient name, patient identification number, medical record number, patient type, date of birth, age, sex, date of admit, and allergies.

In one embodiment, the second label 29 contains only the patient identification number.

Other detailed patient information is stored in the handheld computing device 22. When the patient identification number is downloaded from the second label 29 into the handheld computing device 22, the detailed patient information is displayed on the handheld computing device 22.

As discussed, non-text medication information and patient data in the present invention is provided in machine readable formats. Examples of machine readable formats are: linear bar codes, two-dimensional bar codes such as the two-dimensional data matrix bar codes, other two-dimensional bar code symbologies, other printed data encoding techniques, smart tag or Radio Frequency Identification (RFID) technology, magnetic stripe or tape, Optical Character Recognition (OCR), optical hologram, and the like. The preferred format is the two-dimensional (2D) bar code, such as a 2D data matrix bar code, which provides a large amount of data in a condensed space with a very high readability. The 2D bar code is preferably generated by a software interface application that utilizes the print data stream from a pharmacy information system (PIS) and incorporates the appropriate data fields into the 2D bar code. A key benefit is the ability to generate bar code labels integrated with text without the support of the pharmacy system vendor. For economic and convenience reasons, it is preferred that the same format be used with both the first label 28 and second label 29 so that the information can be read by the same first information input device 36 on the handheld computing device 22. It is quite possible, however, to combine different machine readable formats in this design. For example, a first label 28 on the container 26 can be an RFID label and the second label 29 on the patient tag 24 can be a bar code label.
The handheld computing device 22 is equipped with: means for reading the prescribed medication data, the medication delivery instruction, and the patient data; means for storing information, and means to communicate with other electronic devices. It reads the medication data, medication delivery instruction, and patient data through the first information input device 36 integrated into the handheld computing device 22. It stores the information and performs a matching check to confirm that the medication data match with the patient data, and that the medication is intended for the patient as prescribed. The handheld computing device 22 may also display all or selected information stored. Suitable handheld computing devices include but are not limited to laptop or palmtop computers and personal digital assistants (PDA’s). The preferred handheld computing device is a PDA such as a Palm™ Handheld, various handheld devices from Handspring™, and Pocket PC models from Compaq and Hewlett-Packard. Other brands are also possible. One major advantage of using a PDA is that it can be easily and inexpensively configured to meet the needs of the present invention. An added advantage is that the PDA may be used to provide additional software applications for use by the operator.

The first information input device 36 is integrated into the handheld computing device 22. The device 36 will correspond to the machine readable format selected for the medication information and patient data. Such device includes bar code readers, smart tag readers, magnetic stripe or tape readers, and optical readers. In a preferred embodiment in which the two-dimensional bar codes are employed, the appropriate information input device is a two-dimensional data matrix bar code scanner, such as Symbol’s model 2740 bar code scanner. This bar code scanner is equipped with a charge coupled device (CCD) imager which can capture signatures or other photographic evidence electronically. An example of a CCD imager is a complimentary metal oxide semiconductor (CMOS) device. Once the medication information and patient data are captured by the handheld computing device 22 via the first information input device 36, the information is stored in the handheld computing device 22. The means for storing data within the handheld device 22 includes, for example, various types of memories, cache, magnetic storage, compact disc, optical storage, and the like. A software application is utilized to guide the nurse clinician through the process of checking the prescription against the patient and the handheld computing device 22 displays whether the data is incompatible, unreadable, incomplete, or amiss for some other reason. If the data is complete and compatible, the handheld computing device 22 is programmed to prompt the operator to
transmit and download the medication delivery instruction to the medication delivery device 30. The transmission and downloading is via the first communication device 32 integrated into the handheld computing device 22 for reception by the second communication device 38 integrated into or connected to the medication delivery device 30. The preferred technology for such transmission is infrared transmission in which the first communication device 32 is an infrared transceiver and the pump adapter 34 and second communication device 38 are infrared transceivers in communication with the medication delivery device 30. Alternate methods of communication include wireless communication such as IEEE 802.11, Bluetooth® communication, radio frequency communication, optical communication or wired communication.

The medical device 30 can be a number of different devices. For example, the medical device 30 can be a monitoring device programmed with alarm limits etc. In a preferred embodiment, the medication device 30 is a medication delivery device 30. The medication delivery device 30 also depends on the prescribed medication 27 being administered to the patient. For example, electronic IV infusion pumps or syringe pumps are suitable for intravenous parenteral drugs while inhaled gases can be administered via a ventilator or respirator. The delivery device 30 includes a main processor for controlling operation, including a display and user interface. It is programmable automatically and remotely through a remote input device, such as the handheld computing device 22 of this invention.

In one embodiment in which the delivery device 30 has limited programming and communicating capabilities, the delivery device 30 further comprises a programmable adapter 34 for facilitating the communication, preferably via an infrared transceiver, between the handheld computing device 22 and the medication delivery device 30. The adapter 34 is programmed for reviewing delivery device programming data. The adapter 34 includes hardware and a processor programmed for receiving the prescription data from the handheld computing device 22, determining whether the received prescription data is consistent with operational data input directly to the medication delivery device 30, and enabling the delivery device 30 for operation. In this embodiment, the adapter processor is programmed to guard against incorrect initial programming of the delivery device 30 or incorrect changes in delivery device settings by monitoring the operation of the delivery device 30 and determining whether there is a rate, dose, or drug mismatch or whether the drug is of an incorrect concentration. If
the adapter 34 detects an incorrect parameter at the delivery device 30, either at the start or
during the operation of the delivery device, it sends an alarm signal to alert the operator of the
incorrect parameter. In one embodiment, the alarm signal is sent to the handheld computing
device 22. The adapter 34 may be further programmed to transmit delivery device
configuration data and manually programmed delivery device operation data to and receive
delivery rate information from the handheld computing device 22. It is understood that a
delivery device may have integrated programming and communicating capabilities wherein the
adapter 34 is unnecessary.

In one embodiment, the delivery device 30 determines either a STOP or RUN delivery
status signal based upon the operational data of delivery device 30. If the status signal is RUN
(i.e., the data matches), the delivery device 30 periodically compares delivery device operational
data, including delivery rate data, with the medication delivery instruction contained in the first
label 28 on the medical container 26 during the drug delivery process. In this embodiment, the
device 30 or adapter 34 is programmed to provide an alarm signal if the operational data
changes during the process to a point where the data does not match the delivery device control
data provided by the handheld computing device 22. If the status signal is STOP, the adapter 34
provides an alarm signal. If the adapter 34 receives a STOP status signal, it does not compare
delivery device and patient data. If the adapter 34 determines that the delivery device and
patient data match, a green light signal is preferably provided and the adapter 34 continues to
run. If the adapter 34 determines that the delivery device and patient data do not match, a red
light and alarm are activated. In one embodiment, the adapter 34 sends the alarm signal to the
PDA 22.

The system discussed above, including the handheld computing device 22 and the
adapter 34, can be programmed to include Neofax information, drug facts and comparisons,
American Society of Health-System Pharmacists, and other features such as a dose calculator.
Further, a log file of actual infusion data may be kept by the delivery device 30, the adapter 34,
or the handheld computing device 22.

Further embodiments may include incorporating oral medications into the patient
information data read by the handheld computing device 22, electronic charting (Medication
Administration), inputting outcome analysis (e.g., actual pump delivered data, pain scaling,
infusion timing data), electronic image capture (e.g., such as for wound care and catheter care),
and remote alarm notification to a nurse (via wireless communication). The handheld computing device 22 may be programmed to maintain a log file of patient infusion regimens and communicate the log files through its docking station to an information management system for reporting to the Medication Administration Record (MAR). Other data, which can be captured from the first label 28 on the medication container 26 containing medication information and transferred to the MAR includes container identification, dates of preparation and expiration of the medication, cautions, ordering physician, and prescribed administration route.

The handheld computing device 22 may further be programmed with patient allergy data and drug compatibility charts. In this embodiment, the handheld computing device 22 determines whether the patient is allergic to the prescribed medication or has been administered a medication previously which is not compatible with the present prescribed medication. As shown in FIG. 39, the handheld computing device 22 is programmed to provide an appropriate warning or discontinue the programming routine if warranted.

Detailed operation of one of many possible embodiments for a series of screen displays on the handheld computing device 22 is shown in FIGS. 2 to 34. In this embodiment, the prescribed medication 27 is an IV drug, the medication container 26 is an IV bag, the patient tag 24 is a bracelet worn at the wrist of the patient, the handheld computing device 22 is a PDA, and the medication delivery device 30 is a programmable electronic IV infusion pump equipped with a programmable adapter 34 (see e.g. FIG. 1). The medication data, medication delivery instruction, and the patient data are provided as two-dimensional data matrix bar codes to be read by a bar code scanner incorporated into the personal digital assistant 22. The communication between the PDA 22 and the electronic infusion pump 30 is via infrared transmission from an infrared transceiver integrated into the PDA 22 and an infrared transceiver 38 connected to the infusion pump 30 via an RS-232 connection.

In accord with the present embodiment, FIG. 2 shows an initialization screen of a PDA display 40 having a patient icon 42, an IV icon 44, and a pump icon 46. The initialization screen is generally the first screen displayed on the PDA 22 for programming the system 20 with new patient and medication data. Using a stylus in a manner well known in the art, an operator may enter a patient information mode by tapping or touching the patient icon 42, an IV
information mode by tapping or touching the IV icon 44, or a pump mode by tapping or touching the pump icon 46.

If the patient icon 42 is selected, a patient information screen (FIG. 3) is displayed. The patient information screen may include a numerical screen identifier field 50 (a field that may be present on all screens). For example, the numerical screen identifier 001 corresponds to the patient information screen. The patient information screen includes a patient information summary field 48 and a patient icon 42 for proceeding to screen 002.

Screen 002 is illustrated in FIG. 4, and includes a display for patient ID bracelet scan soft-key display 52(a) and 52(b). To initiate a bracelet scan, an operator positions the PDA 22 appropriately and depresses either button associated with soft-key 52(a) or 52(b). Screen 002 also includes a help icon and a cancel button. Touching the cancel button returns a user to the patient information screen of FIG. 3. Touching the help icon presents an operator with a bracelet scan help screen (numerical identifier 015), an example of which is shown in FIG. 17.

If the patient bracelet scan was successful, the PDA 22 provides a bracelet scan display as shown in FIG. 5, which includes a scan information section 58. The scan information in this display includes the patient identification number, patient name, patient location, medical record number, date of birth, age, date of admission, sex, and the name of the primary physician. Other information can be displayed as desired. The bracelet scan display also includes an IV icon 60 for proceeding to the IV scan page.

In one embodiment, the patient label 29 on the patient bracelet 24 only contains the patient identification number. Detailed patient information is stored in the PDA 22. The PDA 22 scans the label 29 and retrieves and displays the detailed patient information on the PDA 22 as shown in FIG. 5.

If the bracelet scan was not successful, the PDA displays the screen as shown in FIG. 6. This screen includes a soft-key display 62(a) and 62(b) for reinitiating a scan, a help icon 64 for jumping to an unsuccessful scan help page such as that shown in FIG. 21, and a cancel button 66.

FIG. 7 shows an IV container scan initiation display. The display has a soft-key display 68(a) and 68(b), as well as a help icon 70 for jumping to an IV container information help display page, shown in FIG. 19. A cancel button 72 is also included for returning to the bracelet
scan successful display shown in FIG. 5. To initiate a container scan, the operator positions the PDA 22 appropriately and depresses either button associated with the soft-key 68(a) or 68(b).

If the IV scan was successful, the PDA 22 provides an IV scan display as shown in FIGS. 8(a) and 8(b), which includes a scan information section 74. The scan information in these display pages includes patient identification number, patient name, patient location, patient weight, order number, bag identification number, medication identification, volume, and rate, medication preparer’s name and the date and time the preparation was completed, the expiration time and date, the delivery time and date, the administration route. The display could also include an identification of the individual that hung the IV and the date and time the IV was hung. The IV scan display also includes a pump icon 76 for proceeding to the pump page.

If the IV scan was not successful, the PDA displays the screen as shown in FIG. 9. This screen includes a soft-key display 78(a) and 78(b) for reinitiating a scan. A help icon 80 for jumping to the unsuccessful IV scan display shown in FIG. 22, and a cancel button 82 are also included.

If the IV scan was successful, but either patient information or IV information is missing from the PDA database, the PDA 22 provides the display shown in FIG. 10 or FIG. 11. Both screens advise of the information that is missing and allow the operator to move back to the respective scan initiation page, jump to a respective help page or cancel the programming sequence. The respective help pages, shown in FIGS. 23 and 24, advise the operator of the problem and the manner of correction.

If the IV scan was successful, but the patient information does not match the IV information, the PDA 22 provides the display shown in FIG. 12, allowing the operator to jump back to the display for scanning the patient bracelet label 29 or the IV container label 28. This display also has an icon 81 for jumping to the help screen shown in FIG. 25, which explains that the information does not match and the bar codes 28 and 29 should be rescanned.

If a match between the medication data and patient data is confirmed, the PDA 22 displays a manual confirmation screen as shown in FIG. 13(a). After the operator confirms the data match, the operator, by pushing the button 91, can advance to the medication delivery information screen shown in FIG. 13(b). The medication delivery screen in FIG. 13(b) includes soft-keys 83(a) and 83(b). The operator positions the PDA 22 appropriately close to the pump 30 and depresses either button to initiate the transmission of the medication delivery
information from the PDA 22 to the pump 30 via the second communication device 38 integrated with or connected to the medication delivery device 30, or via the adapter 34 in embodiments with the adapter 34. The PDA medication delivery transmission display also includes a help icon 85 for jumping to the display shown in FIG. 26, which instructs the operator regarding the transmission of prescription information from the PDA 22 to the pump 30, and a cancel icon 87, which return to the IV container scan page as shown in FIG. 8(a).

If the medication delivery information was transmitted successfully, the display of FIG. 14 is shown on the PDA 22, and the operator may jump to screen 001 by pressing the continue display icon 93 on the touch-screen, and the PDA 22 will provide the display of FIG. 3, or a similar display depending on the application or other specifics, with information in each field. Examples of displays provided in response to successful transmission of prescription information are shown in FIGS. 16 and 18.

If the medication delivery information was not transmitted successfully, the PDA 22 will display one of a number of messages indicative of whether an error was detected, and if so the cause of the error. If the infrared transmission was incomplete, the display of FIG. 15(a) is shown on the PDA 22, and the operator may press the activation button 95(a) or 95(b) to retransmit. The display also includes a help icon 97 for jumping to the display shown in FIG. 27, which explains potential causes for the transmission error. The display further includes a cancel button 99 for returning to the display of FIG. 8.

If the PDA 22 transmitted the medication delivery information, but did not receive a confirmation from the pump, the display of FIG. 15(b) will be shown. The display of FIG. 15(b) includes a help button for jumping to the help display of FIG. 15(c). This help display 101 in the display of FIG. 15(b) informs the operator of potential problems that may cause the pump to be non-responsive. The operator may then correct the problem and return to the transmit screen by pressing the “OK” button 103.

If the medication delivery information includes data that is outside of the acceptable parameters for the pump, the display of FIG. 15(d) is shown on the PDA 22. A help screen is provided (FIG. 15(e)) for instructing the operator to correct a parameter when the help button 109 is depressed. The operator may jump back to the transmission page by pressing the “OK” button 107.
If the PDA 22 reviews the medication delivery information against the patient allergy data and finds that the medication contains an allergy discrepancy for the patient, the transmission error display of FIG. 15(f) will be shown. The operator may jump to the help screen shown in FIG. 15(g) by depressing the help button 113 for a further explanation of the allergy conflict or exit the present programming string by depressing the cancel button 115.

Additional reasons that may cause the PDA 22 to not immediately proceed with programming the pump are that the medication is being delivered too late and that the medication is being delivered too early. FIGS. 15(h) and 15(j) show the late and early medication delivery displays, respectively. Associated help pages (FIGS. 15(i) and 15(k)) may be accessed to display the specifics of the drug delivery attempt time with respect to the prescribed regimen.

As discussed above, the PDA 22 may also be configured for accessing a patient log. An example of a patient log display is shown in FIG. 20. This display includes a patient identification field 90 and a patient activity field 92. As shown, the patient activity field 92 includes the date and time of activities related to patient infusions listed sequentially. Scroll buttons are provided on the display for progressing to later or earlier times or dates, if applicable. Also, if multiple log pages are existent, an operator may navigate through log pages using previous and next navigation buttons 96(a) and 96(b). If additional log pages do not exist, the PDA displays such a message, as shown in FIG. 28.

The PDA 22 may also retain a record of daily transactions and download the record to an information system, locally at the nursing station or to the central pharmacy computer system, so as to maintain the MAR record electronically versus manually. In one embodiment, the PDA is equipped with a 2D bar code reader having a CCD imager and can capture signatures or other photographic evidence electronically. The PDA 22 may include software to provide the allergy database, drug compatibility charts, and drug handbooks.

The PDA 22 may also include display for programming the pump to administer two or more medications simultaneously. Referring to FIG. 29(a), therein is shown page 1 of a secondary medication data page. FIG. 29(b) shows page 2 of a secondary medication data page. The secondary medication pages identify the patient and also include fields for displaying information regarding specifics of the secondary medication, as well as buttons for jumping to the displays that provide for reading the secondary IV label. FIGS. 37 and 38 show screen
displays associated with a multiple medication configuration. As shown in FIG. 37, the desired medications are selected. In FIG. 38, the primary and secondary medications are selected.

FIGS. 30(a), 30(b), 31(a), and 31(b) show the displays, and respective help displays, shown when the PDA 22 has not received all of the secondary or primary IV information. FIG. 32(a) shows the display provided if the primary and secondary IV information do not correspond to one another. FIG. 32(b) shows the corresponding help page.

FIG. 33 shows a display presented to allow an operator to change the flow rate or volume field data in the PDA 22. An operator taps the “PRI MED” button to jump to the primary medication verbal rate change display of FIG. 34(a) and taps the “SEC MED” button to jump to the secondary medication verbal rate change display of FIG. 34(b). FIG. 34(c) shows the help display provided for each verbal rate change display.

FIG. 35 is a flow chart for processing bar code information to a pump using the PDA 22 for programming the pump with one medication. FIGS. 36(a) - 36(c) show the flow charts for programming the pump with two medications. Referring to FIG. 36(a), the PDA 22 automatically prompts the operator after two medication bar codes have been scanned.

Referring to FIG. 36(c), if the operator does not wish to proceed with two medications, the PDA 22 displays a series of option menus for proceeding with either the first or second scanned medication, or returning to the initial screen. Referring to FIG. 36(b), if the operator wished to proceed with two medications, the PDA 22 prompts the operator to indicate which medication is to be the primary and which is to be the secondary. The operator may also cancel the programming of the pump at any time thorough appropriate button selection. In one embodiment, the operator may scan the bar code 39 on the catheter 37 by the scanning device 36 on the PDA 22 to confirm that the medication 27 is being delivered to the patient via the correct catheter 37. The operator may also scan the bar code 31 on the pump 30 by the scanning device 36 on the PDA 22 to confirm that the proper pump channel is being used if a multi-channel pump is utilized.

The system of the present invention provides a method generally comprising the following steps. First, a medical provider such as a nurse scans the patient bracelet 24 with the PDA 22 and captures the data listed above. The nurse then scans the IV bag label with the PDA 22 and captures the corresponding data listed above. Having received the data, the PDA 22 reports a match or mismatch of the patient bracelet 24 data with the IV bag 26 data. If a match is confirmed, the nurse then downloads the data received from the patient bracelet label 29 and
the IV bag label 28 to the infusion pump 30 via the second communication device 38 integrated with or connected to the medication delivery device 30, or via the adapter 34 in embodiments with the adapter 34. The infusion pump 30 is subsequently enabled to implement that program according to the instruction downloaded from the IV bag label 28. The pump 30 or the adapter 34 sounds an alarm if the delivery rate, drug dose, or drug is subsequently altered from the downloaded data.

The benefits of the medication delivery system in the present invention are significant. At the present time, medication delivery such as IV infusion is driven by a manual set up and verification process, resulting in a significant number of human errors reported each year. The described system reduces such errors by verifying that the right drug is given to the right patient, in the right dose at the right time. The system further prompts a clinician nurse to verify the right route of delivery, and can be further enabled to identify the correct route by using a bar code or RFID tag on the delivery catheter.

It is understood that, given the above description of the embodiments of the invention, various modifications may be made by one skilled in the art. Such modifications are intended to be encompassed by the claims below.
Claims

What is claimed is:

1. A medication delivery system capable of communicating and matching prescribed medication data from a first label on a medication container holding the medication and patient data from a second label on a tag adapted to be worn by a patient wherein the first label also containing instruction of delivering the medication, and the medication and patient data being provided in machine readable formats, the medication delivery system comprising:
   (a) a medical device in communication with the medication container, the medical device adapted to delivering the medication from the container to the patient, the medical device having a data port for receiving information; and
   (b) a handheld computing device having means for reading the prescribed medication data and the patient data and comparing the data to confirm a match between the medication data and patient data, the handheld computing device having a transmitter capable of transmitting the medication delivery instruction from the handheld computing device to the medical device wherein the medical device is adapted to deliver the medication to the patient according to the instructions.

2. The medication delivery system of Claim 1 wherein the handheld computing device is a personal digital assistant.

3. The medication delivery system of Claim 1 wherein the machine readable data of the prescribed medication and the instruction of delivering the prescribed medication are coded in a format selected from the group consisting of: linear bar codes, two-dimensional bar codes, printed data encoding technology, radio frequency identification technology, magnetic stripes or tapes, optical character recognition technology, and optical holograms.

4. The medication delivery system of Claim 1 wherein the machine readable prescribed medication data and medication delivery instruction are coded in two-dimensional bar codes.

5. The medication delivery system of Claim 1 wherein the machine readable patient data is coded in a format selected from the group consisting of: linear bar codes, two-dimensional bar codes, printed data encoding technology, radio frequency identification technology,
technology, magnetic stripes or tapes, optical character recognition technology, and optical holograms.

6. The medication delivery system of Claim 1 wherein the machine readable patient data is coded in two-dimensional bar codes.

7. The medication delivery system of Claim 1 wherein the first label of medication data is a two-dimensional bar code integrated with text.

8. The medication delivery system of Claim 1 wherein the second label of patient data is a two-dimensional bar code integrated with text.

9. The medication delivery system of Claim 1 wherein the first label of medication data is a radio frequency identification programming integrated with text.

10. The medication delivery system of Claim 1 wherein the second label of patient data is a radio frequency identification programming integrated with text.

11. The medication delivery system of Claim 1 wherein the means for reading the prescribed medication data, the medication delivery instruction, and patient data is selected from the group consisting of: bar code scanners, radio frequency identification readers, magnetic stripe or tape readers, and optical readers.

12. The medication delivery system of Claim 1 wherein the means of reading the prescribed medication data, the medical delivery instruction, and the patient data of the handheld computing device is a two-dimensional bar code scanner.

13. The medication delivery system of Claim 1 wherein the transmitter of the handheld computing device is an infrared transceiver.

14. The medication delivery system of Claim 1 wherein the medical device is an electronic infusion pump.

15. The medication delivery system of Claim 1 wherein the medication delivery device further has an adapter to facilitate the communication between the handheld computing device and the medication delivery device.

16. A medication delivery system comprising:

(a) a container holding a medication, the container having a first bar code label in machine readable format containing medication data and a predetermined set of pump instructions for delivering the medication;

(b) a tag adapted to be worn by a patient, the tag having a second bar code label in machine readable format containing patient data;
(c) an infusion pump in communication with the medication container, the pump adapted to deliver the medication from the container to the patient via a catheter, the infusion pump having at least one delivery channel, and the pump having a data port for receiving information; and

(d) a personal digital assistant having a bar code scanner thereon and a data transmitter thereon, the personal digital assistant configured to scan the first bar code label and the second bar code label and compare data from the scanned labels to confirm a match between the medication data and patient data, the personal digital assistant transmitter capable of transmitting the predetermined set of pumping instructions from the personal digital assistant to the infusion pump wherein the pump is adapted to deliver the medication to the patient according to the instructions.

17. The medication delivery system of Claim 16 wherein in the container is an IV bag and the medication is an IV drug.

18. The medication delivery system of Claim 16 wherein the tag containing patient data is a bracelet adapted to be worn by the patient.

19. The medication delivery system of Claim 16 wherein the machine readable format of the first bar code is a two-dimensional bar code.

20. The medication delivery system of Claim 16 wherein the machine readable format of the second bar code is a two-dimensional bar code.

21. The medication delivery system of Claim 16 wherein the first label of medication data is a two-dimensional bar code integrated with text.

22. The medication delivery system of Claim 16 wherein the second label of patient data is a two-dimensional bar code integrated with text.

23. The medication delivery system of Claim 16 wherein the bar code scanner of the personal digital assistant is a two-dimensional bar code scanner.

24. The medication delivery system of Claim 16 wherein the data transmitter on the personal digital assistant is an infrared transceiver and the data port on the pump for receiving information is an infrared transceiver.

25. The medication delivery system of Claim 16 wherein the infusion pump further having an adapter to facilitate the communication between the personal digital assistant and the infusion pump.
26. The medication delivery system of Claim 25 wherein the adapter of the infusion pump further providing infrared data communication between the infusion pump and the personal digital assistant.

27. The medication delivery system of Claim 16 wherein the delivery channel of the infusion pump has a third label containing channel data identifying the channel, the channel data being in a machine readable format to be scanned by the bar code scanner of the personal digital assistant.

28. The medication delivery system of Claim 16 wherein a pharmacy information system generates a print stream containing the medication data and the predetermined set of pump instructions for delivering the medication, and wherein the first bar code label is encoded with the data and instruction derived from the print stream.

29. A medication delivery system comprising:

(a) a medication container containing a prescribed medication and a first label containing data on the prescribed medication, and instruction of delivering the prescribed medication, the medication data and medication delivery instruction being provided in machine readable format;

(b) a tag adapted to be worn by a patient, the tag having a second label containing data on the patient, the patient data being provided in machine readable format;

(c) a handheld computing device with:

means for reading the prescribed medication data, the medication delivery instruction, and the patient data;

means for storing the data; and

means for communicating with other electronic devices; and

(d) an electronic medication delivery device having the means for communicating with the handheld computing device to receive the medication delivery instruction from the handheld device to deliver the prescribed medication in the medication container to the patient via a catheter, the medication delivery device having at least one delivery channel;

wherein the handheld computing device reads and stores the prescribed medication data and the patient data, performs a matching check between the prescribed medication data and the patient data to confirm a match, and communicates the medication delivery instruction to the electronic medication delivery device to deliver the medication to the patient.
30. The medication delivery system of Claim 29 wherein the medication container is an IV bag, the prescribed medication is an IV drug.

31. The medication delivery system of Claim 29 wherein the medication delivery device is an infusion pump.

32. The medication delivery system of Claim 29 wherein the tag containing patient data is a bracelet adapted to be worn by the patient.

33. The medication delivery system of Claim 29 wherein the machine readable data of the prescribed medication and the instructions of delivering the prescribed medication are coded in a format selected from the group consisting of: linear bar codes, two-dimensional bar codes, printed data encoding technology, radio frequency identification technology, magnetic stripes or tapes, optical character recognition technology, and optical holograms.

34. The medication delivery system of Claim 29 wherein the machine readable prescribed medication data and medication delivery instruction are coded in two-dimensional bar codes.

35. The medication delivery system of Claim 29 wherein the machine readable patient data is coded in a format selected from the group consisting of: linear bar codes, two-dimensional bar codes, printed data encoding technology, radio frequency identification technology, magnetic stripes or tapes, optical character recognition technology, and optical holograms.

36. The medication delivery system of Claim 29 wherein the machine readable patient data is coded in two-dimensional bar codes.

37. The medication delivery system of Claim 29 wherein the first label and the second label are generated by a software interface application that utilizes the print data stream from a pharmacy information system.

38. The medication delivery system of Claim 29 wherein the means of reading the prescribed medication data, the medication delivery instruction, and the patient data of the handheld computing device is selected from the group consisting of: bar code scanners, radio frequency identification readers, magnetic stripe or tape readers, and optical readers.

39. The medication delivery system of Claim 29 wherein the means of reading the prescribed medication data, the medical delivery instruction, and the patient data of the handheld computing device is a two-dimensional bar code scanner.
40. The medication delivery system of Claim 29 wherein the first label containing medication data is a two-dimensional bar code with integrated text.

41. The medication delivery system of Claim 29 wherein the second label containing patient data is a two-dimensional bar code with integrated text.

42. The medication delivery system of Claim 29 wherein the first label containing medication data is a radio frequency identification programming with integrated text.

43. The medication delivery system of Claim 29 wherein the second label containing patient data is a radio frequency identification with integrated text.

44. The medication delivery system of Claim 29 wherein the means for communicating with other electronic devices is by infrared transmission.

45. The medication delivery system of Claim 29 wherein the handheld computing device is a personal digital assistant.

46. The medication delivery system of Claim 29 wherein the medication delivery device further comprising an adapter to facilitate the communication between the handheld computing device and the medication delivery device.

47. The medication delivery system of Claim 46 wherein the adapter of the medication delivery device further providing infrared data communication between the medication delivery device and the handheld computing device.

48. The medication delivery system of Claim 29 wherein the medication delivery device has multiple channels, each channel having a third label containing channel data identifying the channel, the channel data being in a machine readable format to be transmitted to the handheld computing device.

49. The medication delivery system of Claim 29 wherein the catheter having a fourth label containing catheter data identifying the catheter, the catheter data being in a machine readable format to be transmitted to the handheld computing device.

50. A medication delivery system capable of communicating and matching prescribed medication data from a first label on a medication container holding the medication and patient data from a second label on a tag adapted to be worn by a patient wherein the first label also containing instruction of delivering the medication, and the data and instruction being provided in machine readable formats, the medication delivery system comprising:

(a) a handheld computing device with:
means for reading the prescribed medication data, medication delivery
instruction, and patient data;
means for storing the data; and
means for communicating with other electronic devices; and

(b) an electronic medication delivery device to deliver the medication to the patient;
wherein the handheld computing device reads the prescribed medication data and the
patient data, performs a matching check to confirm a match between the prescribed medication
data and the patient data, and communicates the instruction of delivering the prescribed
medication to the medication delivery device to deliver the medication to the patient.

51. The medication delivery system of Claim 50 wherein the handheld computing
device is a personal digital assistant.

52. The medication delivery system of Claim 50 wherein the means for reading the
prescribed medication data, the medication delivery instruction, and patient data is selected
from the group consisting of: bar code scanners, radio frequency identification readers,
magnetic stripe or tape readers, and optical readers.

53. The medication delivery system of Claim 50 wherein the means of reading the
prescribed medication data, the medical delivery instruction, and the patient data of the
handheld computing device is a two-dimensional bar code scanner.

54. The medication delivery system of Claim 50 wherein the means for
communicating with other electronic devices is by infrared transmission.

55. The medication delivery system of Claim 50 wherein the medication delivery
device is an electronic infusion pump, the electronic infusion pump having at least one delivery
channel.

56. The medication delivery system of Claim 55 wherein the delivery channel of
the electronic infusion pump having a third label containing channel data identifying the
channel, the channel data being in a machine readable format to be transmitted to the handheld
computing device.

57. The medication delivery system of Claim 50 wherein the medication delivery
device further having an adapter to facilitate the communication between the handheld
computing device and the medication delivery device.
58. The medication delivery system of Claim 57 wherein the adapter of the medication delivery device further providing infrared data communication between the medication delivery device and the handheld computing device.

59. A method for medication delivery comprising the steps of:

(a) providing a medication container containing a prescribed medication and a first label containing data on the prescribed medication and instruction of delivering of the medication, the prescribed medication data and the instruction of delivering the medication being provided in machine readable format;

(b) providing a tag adapted to be worn by a patient, the tag having a second label containing data of the patient, the patient data being provided in machine readable format;

(c) providing a handheld computing device with:

means for reading the prescribed medication data and medication delivery instruction from the first label and patient data from the second label;

means for storing the data and instruction; and

(d) the handheld computing device reading the prescribed medication data and medication delivery instruction from the first label;

(e) the handheld computing device reading the patient data from the second label;

and

(f) the handheld computing device performing a matching check and confirming the match between the prescribed medication data and the patient data.

60. The method of Claim 59 further comprising the step of the handheld computing device communicating and downloading the medication delivery instruction to a medication delivery device to deliver the medication to the patient.

61. The method of Claim 60 further comprising the step of the medication delivery device performing periodic checks of the operating parameters of the medication delivery device against the medication delivery instruction downloaded from the handheld computing device to ensure the operating parameters are within the ranges set by the medication delivery instruction after starting the delivery of the medication.
62. The method of claim 60 wherein the first label is encoded with the prescribed medication data and the instruction of delivering the medication derived from a print stream generated from a pharmacy information system.

63. A method for medication delivery comprising the steps of:

(a) providing a medication container containing a prescribed medication and a first label containing data on the prescribed medication and instruction of delivering of the medication, the prescribed medication data and the instruction of delivering the medication being provided in machine readable format;

(b) providing a tag adapted to be worn by a patient, the tag having a second label containing data of the patient, the patient data being provided in machine readable format;

(c) providing a handheld computing device with:
   means for reading the prescribed medication data and medication delivery instruction from the first label and patient data from the second label;
   means for storing the data and instruction; and

(d) the handheld computing device reading the prescribed medication data and medication delivery instruction from the first label;

(e) the handheld computing device reading the patient data from the second label;

(f) the handheld computing device performing a matching check and confirming the match between the prescribed medication data and the patient data; and

(g) the handheld computing device communicating and downloading the medication delivery instruction to a medication delivery device to deliver the medication to the patient.

64. A method for medication delivery comprising the steps of:

(a) identifying medication data contained in a first label on a medication container containing a prescribed medication, the first label containing data on the prescribed medication and instruction of delivering of the medication, the prescribed medication data and the instruction of delivering the medication being provided in machine readable format;

(b) identifying patient data contained in a second label on a tag adapted to be worn by a patient, the second label containing data of the patient, the patient data being provided in machine readable format;

(c) performing a matching check between the medication data and the patient data by a handheld computing device wherein the handheld computing device having:
means for reading the prescribed medication data and medication delivery instruction from the first label and patient data from the second label; means for storing the data and instruction; and means for communicating data and instruction to other electronic devices; the handheld computing device confirming the data and downloading the instruction of delivering the medication to a medication delivery device.

FIG. 27
TRANSMIT TO PUMP
TRANSMISSION NOT SUCCESSFUL
THE TRANSMISSION FROM THE PALM PILOT TO THE PUMP WAS NOT SUCCESSFUL. THE POTENTIAL CAUSES OF THIS ERROR ARE:

- THE PALM PILOT IR WINDOW WAS NOT AIMED AT THE PUMP IR WINDOW.
- THE PALM PILOT IR WINDOW WAS TOO NEAR THE PUMP IR WINDOW.
- THE PALM PILOT IR WINDOW WAS TOO FAR FROM THE PUMP IR WINDOW.
- THE PUMP IR WINDOW WAS DIRTY.
