COAXIAL LASER ASSISTED COLD SPRAY NOZZLE

CROSS-REFERENCE TO RELATED APPLICATIONS

[0002]

FIELD

[0003] The present disclosure relates to thermal spray coating and, particularly, to a coaxial laser assisted cold spray nozzle.

BACKGROUND

[0004] This section provides background information related to the present disclosure which is not necessarily prior art.

[0005] Thermal spraying is a technique used for coating a substrate, for instance, to protect the substrate against corrosion. Cold spraying is a type of thermal spraying in which a stream of solid particles is accelerated to high speeds by a carrier gas through a nozzle toward the substrate. The particles have enough kinetic energy upon impact with the substrate to deform plastically and bond metallurgically/mechanically to the substrate to form a coating.

[0006] The particles are accelerated to a critical velocity such that the coating can be created. This critical velocity can depend on the properties of the particles and the substrate (i.e., deformability, shape, size, temperature, etc.).

[0007] The particles can also be heated by the carrier gas in order to make the particles more plastic to deform upon impact. The amount of heat
supplied from the gas can depend on the properties of the particles and the substrate.

[0008] Excessively hard substrates (e.g., tool steel) can be difficult to coat by cold spraying. This is because the substrate may not deform enough to allow the particles to bond and form the coating. The impact of the particles can also cause cracking of the substrate.

[0009] In addition, excessively soft substrates (e.g., polymers) can also be difficult to coat using cold spraying techniques. For instance, these substrates may be damaged by impact of the particles and/or the high temperatures of the gas used to accelerate the particles.

[0010] Furthermore, some particles may not be suitable for cold spraying. For instance, excessively hard particles (e.g., ceramics) may not deform sufficiently upon impact with the substrate to bond and coat the substrate.

SUMMARY

[0011] This section provides a general summary of the disclosure, and is not a comprehensive disclosure of its full scope or all of its features.

[0012] A cold spray nozzle assembly for applying a coating of particles to a substrate is disclosed. The nozzle assembly includes a nozzle defining an inner passage with a nozzle exit. The nozzle assembly also includes a particle supply member in communication with the inner passage. The particle supply member supplies the particles to flow and accelerate through the inner passage and out of the nozzle via the nozzle exit toward the substrate to be coated thereon. Furthermore, the nozzle assembly includes a laser that emits a laser beam that is transmitted through the inner passage. The laser heats at least one of the particles and the substrate to promote coating of the substrate with the particles.

[0013] Additionally, a method of applying a coating of particles to a substrate is disclosed. The method includes supplying the particles to flow and accelerate through an inner passage of a nozzle and out of the nozzle via a nozzle exit toward the substrate. The method further includes transmitting a
laser beam through the inner passage to heat at least one of the particles and the substrate to promote coating of the substrate with the particles.

[0014] A cold spray nozzle assembly for applying a coating of particles to a substrate is also disclosed. The nozzle assembly includes a nozzle defining an inner passage with a nozzle entrance, a nozzle exit, and a substantially straight longitudinal axis that extends through both the nozzle entrance and the nozzle exit. The inner passage is rectangular in a cross section taken perpendicular to the longitudinal axis, and the cross section remains rectangular along the entire nozzle from the nozzle entrance to the nozzle exit. The inner passage also includes a convergent section adjacent the nozzle entrance and a divergent section adjacent the nozzle exit. The nozzle also includes a particle supply inlet that is in communication with the divergent section and that extends transverse to the longitudinal axis of the inner passage. The nozzle assembly also includes a particle supply member in communication with the particle supply inlet. The particle supply member supplies the particles to flow and accelerate through the inner passage and out of the nozzle via the nozzle exit toward the substrate to be coated thereon. Moreover, the nozzle assembly includes a gas supply member that supplies a gas to the inner passage to flow through the inner passage of the nozzle to accelerate the particles. Additionally, the nozzle assembly includes a laser that emits a laser beam that is transmitted into the nozzle via the nozzle entrance, through the inner passage, and out of the nozzle via the nozzle exit. The laser heats both the particles and the substrate to promote coating of the substrate with the particles. Furthermore, the nozzle assembly includes a handling device that moves at least one of the nozzle and the substrate relative to the other.

[0014a] In some embodiments, there is provided a cold spray nozzle assembly for applying a coating of particles to a substrate comprising: a nozzle defining an inner passage extending in a flow direction from a convergent section adjacent a nozzle entrance through a throat to a divergent section adjacent a nozzle exit, each of the convergent section, the throat, and the divergent section of the inner passage is substantially rectangular in cross sectional planes that intersect perpendicularly and transversely to a longitudinal axis of the inner passage thereby having opposing minor side faces and major side faces; a gas supply member supplying a gas to the inner passage of the nozzle to flow through the inner passage of the nozzle and accelerate through the inner passage by passage through the convergent section, the throat, and the divergent section; a particle supply member in direct communication with only the minor side face of the divergent section of the inner passage,
the particle supply member supplying the particles to flow in the gas supplied by the
gas supply member, accelerate within the divergent section, and out of the nozzle via the
nozzle exit toward the substrate to coat the substrate; and a laser that emits a laser beam
that is transmitted through the inner passage containing the supplied gas, the laser heats the
particles below the particles’ melting point only in and downstream of the divergent passage
and heats the substrate to promote cold spray coating of the substrate with the particles.

[0014b] In some embodiments, there is provided a cold spray nozzle assembly for
applying a coating of particles to a substrate comprising: a nozzle defining an inner passage
with a nozzle entrance, a nozzle exit, and a substantially straight longitudinal axis that
extends through both the nozzle entrance and the nozzle exit, the inner passage being
substantially rectangular in cross sectional planes that intersect perpendicularly and
transversely to the longitudinal axis along its entirety thereby having opposing minor side
faces and major side faces, the inner passage also including a convergent section adjacent
the nozzle entrance and a divergent section downstream of the convergent section and
adjacent the nozzle exit, the nozzle also including a particle supply inlet that is in direct
communication with only the minor side face of the divergent section; a particle supply
member in communication with the particle supply inlet, the particle supply member supplying
the particles to flow and accelerate within the divergent section, and out of the nozzle via the
nozzle exit toward the substrate to be coated thereon; a gas supply member that supplies a
gas to the inner passage to flow through the inner passage of the nozzle to accelerate the
particles; a laser that emits a laser beam that is transmitted into the nozzle via the nozzle
entrance, through the inner passage containing the supplied gas, and out of the nozzle via
the nozzle exit, the laser heating both the particles below their melting point only in and
downstream of the divergent passage and the substrate to promote cold spray coating of the
substrate with the particles; and a handling device that moves at least one of the nozzle and
the substrate relative to the other.

[0015] Further areas of applicability will become apparent from the description
provided herein. The description and specific examples in this summary are intended for
purposes of illustration only and are not intended to limit the scope of the present disclosure.
DRAWINGS

[0016] The drawings described herein are for illustrative purposes only of selected embodiments and not all possible implementations, and are not intended to limit the scope of the present disclosure.

DETAILED DESCRIPTION

[0024] Example embodiments will now be described more fully with reference to the accompanying drawings.

[0025] Referring initially to FIGS. 1-4, a cold spray nozzle assembly is illustrated according to various exemplary embodiments of the present disclosure. The cold spray nozzle assembly can be used for applying a coating of particles to a substrate (FIGS. 1, 5, and 6) as will be described in greater detail below.

[0026] The assembly can include a nozzle having a substantially straight longitudinal axis X. As shown in FIGS. 2-4, the nozzle can define an inner passage that extends parallel to the axis X. The inner passage can also include a nozzle entrance and a nozzle exit at opposite ends thereof (FIGS. 2-4). As best shown in FIG. 4, the inner passage can include a
convergent section 24 adjacent the nozzle entrance 20 and a divergent section 26 adjacent the nozzle exit 22. More specifically, both the convergent and divergent sections 24, 26 can be tapered. The convergent section 24 narrows moving away from the entrance 20, and the divergent section 26 widens moving toward the exit 22. The convergent section 24 is connected to the divergent section 26 to define a shoulder 27 (FIG. 4). As will be discussed, the particles 12 flow through the inner passage 18, and the convergent and divergent sections 24, 26 ensure an appropriate flow field in the passage 18 such that the particles 12 move at a sufficient velocity to coat the substrate 14.

[0027] As shown in FIG. 1, the exit 22 can be substantially rectangular in shape. More specifically, the inner passage 18 can have a substantially rectangular cross section taken perpendicular to the axis X adjacent the exit 22. The entire inner passage 18 can have a similar substantially rectangular cross section along the entire axis X of the passage 18; however, it will be apparent that the area of such a cross section will change along the axis X due to the tapering of the convergent and divergent sections 24, 26. It will also be appreciated that the inner passage 18 and the exit 22 can alternatively have any suitable (non-rectangular) shape.

[0028] Furthermore, as shown in Fig. 4, the nozzle 16 can include one or more particle supply inlets 28a, 28b. The nozzle 16 can include any number of inlets 28a, 28b, and the inlets 28a, 28b can be disposed in any suitable location. In the embodiment shown, there are two inlets 28a, 28b disposed symmetrically on opposite sides of the axis X. The particle supply inlets 28a, 28b can each extend transverse to the axis X. For instance, the particle supply inlets 28a, 28b can each be disposed at a positive acute angle relative to the axis X and generally toward the exit 22.

[0029] As shown in FIG. 1, the assembly 10 can include a particle supply member, shown schematically at 30. The particle supply member 30 can be in (fluid) communication with the inner passage 18 of the nozzle 16 via the inlets 28a, 28b. For instance, the particle supply member 30 can include one or more tubes 29a, 29b (FIGS. 1-3) that are received in and operably coupled to the inlets 28a, 28b, respectively. Thus, as will be discussed, the particles 12 can
be supplied from the tubes 29a, 29b of the supply member 30 to flow through the
inlets 28a, 28b, through the inner passage 18, and out of the nozzle exit 22
toward the substrate 14 to coat the substrate 14 with the particles 12.

[0030] It will be appreciated that the particles 12 can be of any suitable
type. For instance, the particles 12 can be metallic, polymeric, and/or ceramic
powderized particles 12. Also, the particles 12 can be a composite mixture of
metallic, polymeric, and/or ceramic particles 12.

[0031] Referring to FIGS. 1-3, the assembly 10 can further include a
pressure tube 32. The pressure tube 32 can include a first branch 34, a second
branch 36, and a third branch 38, each of which are hollow and that are in fluid
communication with each other. The first, second, and third branches 34, 36, 38
can also be in fluid communication with the nozzle entrance 20. The first branch
34 can be directly fixed to the nozzle 16 so as to be coaxial with the axis X. The
second branch 36 and the third branch 36, 38 can be disposed at an acute angle
relative to the axis X and can be directed generally toward the nozzle entrance
20. The third branch 38 can be disposed between the second branch 36 and the
nozzle entrance 20.

[0032] Moreover, as shown in FIG. 1, the assembly 10 can include a
gas supply member 31. The gas supply member 31 can be in fluid
communication with the second branch 36 of the pressure tube 32. The gas
supply member 31 can supply any suitable gas to pressurize the inner passage
18 of the nozzle 16.

[0033] Moreover, the assembly 10 can include a laser 40. The laser
40 can be of any suitable type, such as a diode laser of a known type. The laser
40 can include a fiber-optic cable 42 and at least one or more (e.g., three) lenses
44a, 44b, 44c (FIG. 2). The laser 40 can be operably coupled to the first branch
34 of the pressure tube 32 so as to be substantially coaxial with the axis X. As
will be discussed, the laser 40 can emit a laser beam 46 (FIGS. 1 and 3) that is
transmitted through the entrance 20 of the inner passage 18 of the nozzle 16
and out of the nozzle 16 via the exit 22 toward the substrate 14. The laser beam
46 can be directed substantially parallel to and coaxial to the axis X toward the
substrate 14, although some degree of spread of the beam 46 away from the
axis X can occur.

[0034] As shown in FIG. 1, the assembly 10 can further include a
platform 49 on which the pressure tube 32 and the laser 40 are mounted. The
assembly 10 can also include a handling device 50 that moves the platform 49
and/or the substrate 14 relative to each other. In the embodiment shown, the
handling device 50 is operably coupled to the platform 49 such that the platform
49 can move while the substrate 14 remains stationary; however, it will be
appreciated that the handling device 50 could move the substrate 14 while the
platform 49 remains stationary, or the handling device 50 could be configured to
move both the platform 49 and the substrate 14 relative to each other. The
handling device 50 can be of any suitable type, such as a robotic handling
device 50. When the handling device 50 moves the platform 49, the laser 40,
the pressure tube 32, and the nozzle 16 are moved as a unit relative to the
substrate 14.

[0035] Additionally, the assembly 10 can include a controller 52. The
controller 52 can be of any suitable type, such as a programmable computer.
The controller 52 can be in communication with the laser 40, the handling device
50, the gas supply member 31, and the particle supply member 30 for operating
each. The controller 52 can also be in communication with the third branch 38
for receiving feedback regarding the pressure inside the pressure tube 32 and
the nozzle 16. For instance, a pressure sensor (not shown) can be operably
coupled to the third branch 38 to detect pressure inside the pressure tube 32 and
nozzle 16, and the pressure sensor can also provide correlative electronic
feedback signals to the controller 52 for controlling the assembly 10.

[0036] During operation, the controller 52 can move the assembly 10
into a desired position relative to the substrate 14 using the handling device 50.
When in proper position, the controller 52 can operate the laser 40 to emit the
laser beam 46 through the pressure tube 32, through the nozzle 16, and toward
the substrate 14. The energy of the laser beam 46 can heat the substrate 14 to
make the substrate 14 more amenable to plastic deformation and to prepare the
substrate 14 for coating. It will be appreciated that this “pre-treating” of the
substrate 14 can be skipped in some embodiments, depending on the type of material of the substrate 14.

[0037] Also, in some embodiments, the controller 52 can cause the gas supply member 31 to supply gas into the inner passage 18 and to the substrate 14 before and during operation of the laser 40. As such, the gas can reduce the likelihood of oxidation of the substrate 14.

[0038] After the laser 40 has begun operating, the controller 52 can cause the particle supply member 30 to supply the particles 12. The particles 12 can be accelerated by the gas up to or beyond a critical velocity within the inner passage 18 and directed toward the substrate 14. The energy of the laser beam 46 can heat the particles 12 during flight toward the substrate 14. Because the particles 12 are heated, the particles 12 can plastically deform more readily when the particles 12 impact the substrate 14.

[0039] Furthermore, the energy of the laser beam 46 can continue to heat the substrate 14 as the particles 12 are ejected toward the substrate 14. Thus, the substrate 14 can plastically deform more readily.

[0040] The handling device 50 can continuously move the assembly 10 to evenly coat the substrate 14 with the particles 12 on predetermined areas. An example of the coating 11 on a planar substrate 14 is shown in FIG. 5, and an example of the coating 11 on a tubular substrate 14 is shown in FIG. 6.

[0041] Accordingly, the assembly 10 can be used to coat a substrate 14 with particles 12. A wider variety of substrates 14 can be used (e.g., harder or softer substrates 14) as compared with substrates typically used in cold spray coating processes. Specifically, the particles 12 can be supplied at relatively low pressures because heating of the particles 12 is caused by the laser 40 instead of just the high pressure gas as in prior art systems. Likewise, the critical velocity of the particles 12 can be reduced for the same reasons. For these reasons, the impact of the particles 12 is less likely to damage the substrate 14. Accordingly, the substrate 14 can be softer or harder than substrates typically coated by cold spray coating processes.

[0042] Also, a wider variety of particles 12 can be used (e.g., harder or softer composite particles 12) as compared with particles typically used in cold
spray coating processes. This is because the laser 40 heats the particles 12 prior to impact with the substrate 14 and allows the particles 12 to more readily plasticly deform.

[0043] In addition, the substrate 14 does not necessarily need to be protected from oxidation (e.g., in a protected environmental chamber). This is because the area of the substrate 14 affected by the laser beam 46 remains within the stream of gas supplied by the gas supply member 31.

[0044] Additionally, because of the rectangular cross section of the inner passage 18 and because of the rectangular shape of the nozzle exit 22, the particles 12 can be deposited at a fairly even thickness on the substrate 14 (see FIGS. 5 and 6) as compared with prior art systems. Accordingly, the finished part can be more aesthetically pleasing, can fit better to other parts, and can have better corrosion resistance due to in-situ annealing.

[0045] The foregoing description of the embodiments has been provided for purposes of illustration and description. It is not intended to be exhaustive or to limit the present disclosure. Individual elements or features of a particular embodiment are generally not limited to that particular embodiment, but, where applicable, are interchangeable and can be used in a selected embodiment, even if not specifically shown or described. The same may also be varied in many ways. Such variations are not to be regarded as a departure from the present disclosure, and all such modifications are intended to be included within the scope of the present disclosure.
CLAIMS:

1. A cold spray nozzle assembly for applying a coating of particles to a substrate comprising:
   - a nozzle defining an inner passage extending in a flow direction from a convergent section adjacent a nozzle entrance through a throat to a divergent section adjacent a nozzle exit, each of the convergent section, the throat, and the divergent section of the inner passage is substantially rectangular in cross sectional planes that intersect perpendicularly and transversely to a longitudinal axis of the inner passage thereby having opposing minor side faces and major side faces;
   - a gas supply member supplying a gas to the inner passage of the nozzle to flow through the inner passage of the nozzle and accelerate through the inner passage by passage through the convergent section, the throat, and the divergent section;
   - a particle supply member in direct communication with only the minor side face of the divergent section of the inner passage, the particle supply member supplying the particles to flow in the gas supplied by the gas supply member, accelerate within the divergent section, and out of the nozzle via the nozzle exit toward the substrate to coat the substrate; and
   - a laser that emits a laser beam that is transmitted through the inner passage containing the supplied gas, the laser heats the particles below the particles’ melting point only in and downstream of the divergent passage and heats the substrate to promote cold spray coating of the substrate with the particles.

2. The cold spray nozzle assembly of claim 1, wherein the inner passage has a substantially straight longitudinal axis, and wherein the laser beam is directed substantially parallel and coaxial to the longitudinal axis, out of the nozzle exit, and toward the substrate.

3. The cold spray nozzle assembly of claim 2, wherein the inner passage includes a nozzle entrance, wherein the longitudinal axis extends through both the nozzle entrance and the nozzle exit, and wherein the laser is operably coupled to the nozzle such that the laser beam is transmitted into the nozzle via the nozzle entrance.

4. The cold spray nozzle assembly of claim 1, further comprising a pressure tube that is disposed between the laser and the nozzle, the pressure tube being in fluid communication with the inner passage, and further comprising a gas supply member that
supplies a gas to the pressure tube to flow through the inner passage of the nozzle and out of the nozzle exit.

5. A cold spray nozzle assembly for applying a coating of particles to a substrate comprising:
   a nozzle defining an inner passage with a nozzle entrance, a nozzle exit, and a substantially straight longitudinal axis that extends through both the nozzle entrance and the nozzle exit, the inner passage being substantially rectangular in cross sectional planes that intersect perpendicularly and transversely to the longitudinal axis along its entirety thereby having opposing minor side faces and major side faces, the inner passage also including a convergent section adjacent the nozzle entrance and a divergent section downstream of the convergent section and adjacent the nozzle exit, the nozzle also including a particle supply inlet that is in direct communication with only the minor side face of the divergent section;
   a particle supply member in communication with the particle supply inlet, the particle supply member supplying the particles to flow and accelerate within the divergent section, and out of the nozzle via the nozzle exit toward the substrate to be coated thereon;
   a gas supply member that supplies a gas to the inner passage to flow through the inner passage of the nozzle to accelerate the particles;
   a laser that emits a laser beam that is transmitted into the nozzle via the nozzle entrance, through the inner passage containing the supplied gas, and out of the nozzle via the nozzle exit, the laser heating both the particles below their melting point only in and downstream of the divergent passage and the substrate to promote cold spray coating of the substrate with the particles; and
   a handling device that moves at least one of the nozzle and the substrate relative to the other.

6. The cold spray nozzle assembly of claim 1, wherein the divergent section is larger than the convergent section at the throat resulting in formation of a shoulder at the throat, the shoulder being a flat surface parallel to the vertical planes perpendicular to the longitudinal axis of the inner passage, and
   wherein the particle supply member in direct communication with the divergent section of the inner passage is downstream from the shoulder.
