(54) Title: GRAFT SYSTEMS HAVING FILLING STRUCTURES SUPPORTED BY SCAFFOLDS AND METHODS FOR THEIR USE

(57) Abstract: Aneurysms are treated by filling at least one double-walled filling structure with a curable medium within the aneurysm. The filling structures may be delivered over balloon deployment mechanisms in order to shape and open tubular lumens therethrough. Scaffolds are placed into the tubular lumens in order to help maintain the shape, anchor the filling structures in place, and provide improved blood flow transition into and out of the tubular lumens.

## GRAFT SYSTEMS HAVING FILLING STRUCTURES SUPPORTED BY SCAFFOLDS AND METHODS FOR THEIR USE

### BACKGROUND OF THE INVENTION

5 [0001] 1. Field of the Invention. The present invention relates generally to medical apparatus and methods for treatment. More particularly, the present invention relates to expandable prosthesis and methods for treating abdominal and other aneurysms.

[0002] Aneurysms are enlargements or "bulges" in blood vessels which are often prone to rupture and which therefore present a serious risk to the patient. Aneurysms may occur in  
10 any blood vessel but are of particular concern when they occur in the cerebral vasculature or the patient's aorta.

[0003] The present invention is particularly concerned with aneurysms occurring in the aorta, particularly those referred to as aortic aneurysms. Abdominal aortic aneurysms (AAA's) are classified based on their location within the aorta as well as their shape and  
15 complexity. Aneurysms which are found below the renal arteries are referred to as infrarenal abdominal aortic aneurysms. Suprarenal abdominal aortic aneurysms occur above the renal arteries, while thoracic aortic aneurysms (TAA's) occur in the ascending, transverse, or descending part of the upper aorta.

[0004] Infrarenal aneurysms are the most common, representing about seventy percent  
20 (70%) of all aortic aneurysms. Suprarenal aneurysms are less common, representing about 20% of the aortic aneurysms. Thoracic aortic aneurysms are the least common and often the most difficult to treat. Most or all present endovascular systems are also too large (above 12F) for percutaneous introduction.

[0005] The most common form of aneurysm is "fusiform," where the enlargement extends  
25 about the entire aortic circumference. Less commonly, the aneurysms may be characterized by a bulge on one side of the blood vessel attached at a narrow neck. Thoracic aortic aneurysms are often dissecting aneurysms caused by hemorrhagic separation in the aortic wall, usually within the medial layer. The most common treatment for each of these types and forms of aneurysm is open surgical repair. Open surgical repair is quite successful in  
30 patients who are otherwise reasonably healthy and free from significant co-morbidities. Such

open surgical procedures are problematic, however, since access to the abdominal and thoracic aortas is difficult to obtain and because the aorta must be clamped off, placing significant strain on the patient's heart.

[0006] Over the past decade, endoluminal grafts have come into widespread use for the treatment of aortic aneurysm in patients who cannot undergo open surgical procedures. In general, endoluminal repairs access the aneurysm "endoluminally" through either or both iliac arteries in the groin. The grafts, which typically have been fabric or membrane tubes supported and attached by various stent structures, are then implanted, typically requiring several pieces or modules to be assembled *in situ*. Successful endoluminal procedures have a much shorter recovery period than open surgical procedures.

[0007] Present endoluminal aortic aneurysm repairs, however, suffer from a number of limitations. A significant number of endoluminal repair patients experience leakage at the proximal juncture (attachment point closest to the heart) within two years of the initial repair procedure. While such leaks can often be fixed by further endoluminal procedures, the need to have such follow-up treatments significantly increases cost and is certainly undesirable for the patient. A less common but more serious problem has been graft migration. In instances where the graft migrates or slips from its intended position, open surgical repair is required. This is a particular problem since the patients receiving the endoluminal grafts are often those who are not considered good candidates for open surgery. Further shortcomings of the present endoluminal graft systems relate to both deployment and configuration. The multiple component systems require additional time for introducing each piece and even more time for assembling the pieces *in situ*. Such techniques are not only more time consuming, they are also more technically challenging, increasing the risk of failure. Current devices are also unsuitable for treating many geometrically complex aneurysms, particularly infrarenal aneurysms with little space between the renal arteries and the upper end of the aneurysm, referred to as short-neck or no-neck aneurysms. Aneurysms having torturous geometries, are also difficult to treat.

[0008] A particularly promising endoluminal graft is described in U.S. Publication No. 2006/0025853, which corresponds to parent application U.S. Application No. 11/187,471, the full disclosure of which has previously been incorporated herein by reference. That patent application describes the treatment of the aortic and other aneurysms with a double-walled structure which is filled with a hardenable material which has cured

*in situ*. The structure conforms to the shape of the aneurysmal space and resists migration and endoleaks. The particular design described, however, has certain shortcomings. For example, the lumen provided by the inner wall of the filled structure can sometimes deform so that the shape of the lumen is less than ideal. In other rare instances, leakage paths on the aortic or iliac ends of the graft may form.

[0009] For these reasons, it would be desirable to provide improved methods, systems, and prostheses for the endoluminal treatment of aortic aneurysms. Such improved methods, systems, and treatments should preferably provide implanted prosthesis which result in minimal or no endoleaks, resist migration, are relatively easy to deploy, have a low introduction profile (preferably below 12F), and can treat most or all aneurysmal configurations, including short-neck and no-neck aneurysms as well as those with highly irregular and asymmetric geometries. Further it would be desirable to provide fillable aneurysmal grafts having supported inner blood flow lumens and improved blood flow transitions at the aortic and/or iliac ends. At least some of these objectives will be met by the inventions described hereinafter.

[0010] 2. Description of the Background Art. Grafts and endografts having fillable components are described in U.S. Patent Nos. 4,641,653; 5,530,528; 5,665,117; and 5,769,882; U.S. Patent Publications 2004/0016997; and PCT Publications WO 00/51522 and WO 01/66038. The following patents and published applications describe stents and grafts having cuffs, extenders, liners, and related structures: U.S. Patent Nos. 6,918,926; 6,843,803; 6,663,667; 6,656,214; 6,592,614; 6,409,757; 6,334,869; 6,283,991; 6,193,745; 6,110,198; 5,994,750; 5,876,448; 5,824,037; 5,769,882; 5,693,088; and 4,728,328; and U.S. Published Application Nos. 2005/0028484; 2005/0065592; 2004/0082989; 2004/0044358; 2003/0216802; 2003/0204249; 2003/0204242; 2003/0135269; 2003/0130725; and 2002/0052643.

#### BRIEF SUMMARY OF THE INVENTION

[0011] The present invention provides methods and systems for the endoluminal treatment of aneurysms, particularly aortic aneurysms including both abdominal aortic aneurysms (AAA's) and thoracic aortic aneurysms (TAA's). The systems include prostheses which comprise double-walled filling structures which are pre-shaped and otherwise adapted to substantially fill the enlarged volume of an aneurysm, particularly a fusiform aneurysm, leaving a lumen in place for blood flow.

[0012] The double-walled filling structures will thus usually have a generally toroidal structure with an outer wall, an inner wall, a potential space or volume between the outer and inner walls to be filled with a filling medium, and a generally tubular lumen inside of the inner wall which provides the blood flow lumen after the prosthesis has been deployed. The shape of the filling structure will be preferably adapted to conform to the aneurysm being treated. In some instances, the filling structure can be shaped for the aneurismal geometry of a particular patient using imaging and computer-aided design and fabrication techniques. In other instances, a family or collection of filling structures will be developed having different geometries and sizes so that a treating physician may select a specific filling structure to treat a particular patient based on the size and geometry of that patient's aneurysm. In all instances, the outer wall of the filling structure will conform or be conformable to the inner surface of the aneurysm being treated. While the inner wall of the structure will be aligned with lumens of the blood vessels on either side of the prosthesis after the prosthesis has been deployed.

[0013] The filling structures of the prosthesis will usually be formed from a non-compliant material, such as parylene, polyester (e.g., Dacron<sup>®</sup>), PET, PTFE, and/or a compliant material, such as silicone, polyurethane, latex, or combinations thereof. Usually, it will be preferred to form at least the outer wall partially or entirely from a non-compliant material to enhance conformance of the outer wall to the inner surface of the aneurysm. This is particularly true when the aneurysm has been individually designed and/or sized for the patient being treated.

[0014] The walls of the filling structures may consist of a single layer or may comprise multiple layers which are laminated, glued, heat bonded, ultrasonically bonded, or otherwise formed together. Different layers may comprise different materials, including both compliant and/or non-compliant materials. The structure walls may also be reinforced in various ways, including braid reinforcement layers, filament reinforcement layers, and the like.

[0015] In addition to the filling structures just described, the aneurysm treatment systems of the present invention will further include at least a first scaffold separate from the filling structure, where the scaffold can be expanded within the generally tubular lumen which provides the blood flow after the filling structure has been deployed in the aneurysm. The first scaffold will be adapted to expand within at least a first portion of the tubular lumen of the filling structure and may provide one or more specific advantages. For example, the

scaffold may support and smooth the inside wall of the tubular lumen which in some cases might otherwise become uneven during hardening of the polymer fill. Scaffolds may also provide for anchoring of the filling structure, particularly at the aortic end of the graft when placed in an AAA. The scaffold may be partly or wholly covered with a membrane in order to form a graft. In such cases, the graft structure may help provide a transition from the blood vessel into the generally tubular lumen of the filling structure from the aortic end.

Alternatively, the graft structure could provide one or a pair of transitions out of the iliac end of the filling structure. In a particular example, a graft structure can be used on either side of the filling structure in order to treat additional or continuing aneurysmal regions in the adjacent blood vessel.

[0016] The scaffolds used in combination with the double-walled filling structures of the present invention may take any form generally associated with a vascular or other luminal stents or grafts. For example, the scaffolds may be formed from an elastic material, particularly a spring steel or shape memory alloy, so that they may be delivered in a constrained configuration and allowed to expand *in situ* to anchor within the generally tubular lumen of the filling structure. Alternatively, the scaffold may be formed from a malleable metal or other material, such as stainless steel, and be delivered using a balloon catheter or other conventional stent expansion device. Grafts will usually comprise a metal frame covered in part or in whole by a membrane material, such as polyester, PTFE, or the like.

[0017] The geometry of the scaffold may also vary considerably. Often, the scaffold will extend over substantially the entire length of the inner wall of the generally tubular lumen of the filling structure. Frequently, the scaffold will extend outwardly from at least one of the ends of the generally tubular lumen into the adjacent blood vessel. The scaffold may also extend outwardly from both ends of the generally tubular lumen as well as covering the entire inner wall surface of that lumen.

[0018] In other instances, multiple scaffold structures may be provided within a single generally tubular lumen of the filling structure. In such cases, the two or more scaffolds may be adapted to be placed in series, frequently overlapping. In other instances, scaffolds may be adapted to be spaced apart at either or both ends and optionally at regions between the ends. In the case of covered scaffolds, the scaffold will typically comprise a metal frame, at least a portion of which is covered by a polymeric membrane or other covering. In other instances, however, the scaffold or portions thereof may be polymeric and optionally formed

from a biodegradable polyester. It will frequently be desirable to cover the outside of the scaffold over at least those portions of the scaffold which engage the inner wall of the generally tubular lumen of the filling structure. The scaffolds and/or their covers may be coated with, impregnated with, or otherwise coupled to drugs or other bioactive substances for a variety of purposes, such as promoting tissue ingrowth, reducing thrombosis, reducing the risk of invention, and the like.

[0019] Preferred delivery protocols for the filling structures will utilize delivery catheters having a balloon or other expandable support for carrying the filling structure. When using balloons, the balloons will preferably be substantially or entirely non-compliant, although compliant and combination compliant/non-compliant balloons may also find use. The balloon or other mechanical expansion components of the delivery catheter will initially be disposed within the inner tubular lumen of the filling structure, with the filling structure generally being collapsed into a low width or low profile configuration over the expansion element. The delivery catheter may then be introduced intraluminally, typically into the iliac artery and upwardly to the region within the aorta to be treated. The delivery catheter will also include one or more lumens, tubes, or other components or structures for delivering the filling medium in a fluid form to an internal filling cavity of the filling structure. Thus, the delivery catheter can be used to both initially place and locate the filling structure of the prosthesis at the aneurismal site. Once at the aneurismal site, the internal tubular lumen of the structure can be expanded using the balloon or other expandable element on the delivery catheter. The filling structure itself will be filled and expanded by delivering the filling medium via the catheter into the internal volume of the filling structure. Both expansion and filling operations may be performed simultaneously, or can be performed in either order, i.e. the filling structure may be filled first with the delivery catheter balloon being expanded second, or vice versa. The filling structure(s) and/or delivery balloons may have radiopaque markers to facilitate placement and/or pressure sensors for monitoring filling and inflation pressures during deployment.

[0020] In preferred aspects of the present invention, the filling structure will be filled with a fluid (prior to hardening as described herein below) at a pressure which is lower than that of the expansion force provided by the delivery catheter, typically the filling pressure of the expandable balloon. Typically, the filling structure will be filled with filling medium at a pressure from 80 mm of Hg to 1000 mm of Hg, preferably from 200 mm of Hg to 600 mm of Hg, while the delivery balloon is inflated to a pressure in the range from 100 mm of Hg to

5000 mm of Hg, preferably from 400 mm of Hg to 1000 mm of Hg. These pressures are gage pressures, i.e. measured relative to atmospheric pressure.

[0021] As described thus far, in the present invention includes delivery of a single prosthesis and filling structure to an aneurysm. Delivery of a single filling structure will be particularly suitable for aneurysms which are remote from a vessel bifurcation so that both ends of the filling structure are in communication with only a single blood vessel lumen. In the case of aneurysms located adjacent a vessel bifurcation, such as the most common, infrarenal abdominal aortic aneurysms, it will often be preferable to utilize two such filling structures introduced in a generally adjacent, parallel fashion within the aneurismal volume. In the specific case of the infrarenal aneurysms, each prosthesis will usually be delivered separately, one through each of the two iliac arteries. After locating the filling structures of the prosthesis within the aneurismal space, they can be filled simultaneously or sequentially to fill and occupy the entire aneurismal volume, leaving a pair of blood flow lumens.

[0022] Suitable filling materials will be fluid initially to permit delivery through the delivery catheter and will be curable or otherwise hardenable so that, once in place, the filling structure can be given a final shape which will remain after the delivery catheter is removed. The fillable materials will usually be curable polymers which, after curing, will have a fixed shape with a shore hardness typically in the range from 10 durometer to 140 durometer. The polymers may be delivered as liquids, gels, foams, slurries, or the like. In some instances, the polymers may be epoxies or other curable two-part systems. In other instances, the polymer may comprise a single material which, when exposed to the vascular environment within the filling structure, changes state over time, typically from zero to ten minutes.

[0023] In a preferred aspect of the present invention, after curing, the filling material will have a specific gravity, typically in the range from 0.1 to 5, more typically from 0.8 to 1.2 which is generally the same as blood or thrombus. The filling material may also include bulking and other agents to modify density, viscosity, mechanical characteristics or the like, including microspheres, fibers, powders, gasses, radiopaque materials, drugs, and the like. Exemplary filling materials include polyurethanes, collagen, polyethylene glycols, microspheres, and the like.

[0024] The filling structures may be modified in a variety of other ways within the scope of the present invention. For example, the external surfaces of the filling structures may be partially or entirely modified to enhance placement within the aneurismal space, typically by

promoting tissue ingrowth or mechanically interlocking with the inner surface of the aneurysm. Such surface modifications include surface roughening, surface stippling, surface flocking, fibers disposed over the surface, foam layers disposed over the surface, rings, and the like. It is also possible to provide biologically active substances over all or a portion of the external surface of the filling structure, such as thrombogenic substances, tissue growth promotants, biological adhesives, and the like. It would further be possible to provide synthetic adhesives, such as polyacrylamides, over the surface to enhance adherence.

[0025] In some instances, it will be desirable to modify all or a portion of the internal surface of the filling structure. Such surface modifications may comprise surface roughening, rings, stipples, flocking, foam layers, fibers, adhesives, and the like. The purpose of such surface modification will usually be to enhance the filling and bonding to the filling material, and to control the minimum wall thickness when the structure is filled particularly after the filling material has been cured. In particular instances, locations of the filling structure may be pressed together when the structure is deployed, thus potentially excluding filling material. In such instances, it will be desirable if the surfaces of the filling structure can adhere directly to each other.

[0026] In view of the above general descriptions of the present invention, the following specific embodiments may be better understood. In a first specific embodiment, methods for treating an aneurysm comprise positioning at least one double-walled filling structure across the aneurysm. By "across" the aneurysms, it is meant generally that the filling structure will extend axially from one anatomical location which has been identified by imaging or otherwise as the beginning of the aneurysm to a space-part location (or locations in the case of bifurcated aneurysm) where it has been established that the aneurysm ends. After positioning, the at least one filling structure is filled with a fluid filling medium so that an outer wall of the structure conforms to the inside of the aneurysm and an inner wall of the structure forms a generally tubular lumen to provide for blood flow after the filling structure has been deployed. While the filling structure is being filled, after the filling structure has been filled, or during both periods, the tubular lumen will preferably be supported, typically by a balloon or mechanically expansible element. After the filling structure has been filled, the filling material or medium is hardened while the tubular lumen remains supported. Supporting the tubular lumen during hardening assures that the lumen will have a desired geometry, will properly align with adjacent vascular lumens and that the tubular lumen being formed remains aligned with the native aortic and/or iliac artery lumens after the prosthesis

has been fully implanted. Preferably, the support will be provided by a balloon which extends proximally and distally of the filling structure where the balloon may slightly "overexpand" in order to assure the desired smooth transition and conformance of the tubular lumen provided by the filling structure with the native vessel lumens.

5 [0027] After hardening, the support will be removed, leaving the filling structure in place. In some instances, however, prior to hardening, it will be desirable to confirm proper placement of the filling structure. This can be done using imaging techniques or otherwise testing for patency and continuity. In some instances, it may be desirable to first fill the  
10 of the filling structure is appropriate for the patient being treated. After testing, the saline may be removed and replaced with the hardenable filler.

[0028] In a second specific embodiment of the present invention, abdominal aortic aneurysms and other bifurcated aneurysms are treated by positioning first and second double-walled filling structures within the aneurismal volume. The first and second double-walled  
15 filling structures are positioned across the aneurysm, as defined above, extending from the aorta beneath the renal arteries to each of the iliac arteries, respectively. The first fluid filling structure is filled with a fluid filling material, the second filling structure is also filled with a fluid material, and the outer walls of each filling structure will conform to the inside surface of the aneurysm as well as to each other, thus providing a pair of tubular lumens for blood  
20 flow from the aorta to each of the iliac arteries. Preferably, the tubular lumens of each of the first and second filling structures are supported while they are being filled or after they have been filled. Further, the tubular lumens will preferably remain supported while the filling material is hardened, thus assuring that the transitions to the tubular lumens to the native vessel lumens remain properly aligned and conformed.

25 [0029] In a third specific embodiment of the present invention, systems for treating aneurysms comprise at least one double-walled filling structure and at least one delivery catheter having an expandable support positionable within a tubular lumen of the filling structure. The systems will usually further comprise a suitable hardenable or curable fluid filling medium. The particular characteristics of the filling structure and delivery balloon  
30 have been described above in connection with the methods of the present invention.

[0030] In a still further specific embodiment of the present invention, a system for treating abdominal aortic aneurysms comprises a first double-walled filling structure and a second

double-walled filling structure. The first and second filling structures are adapted to be filled with a hardenable filling medium while they lie adjacent to each other within the aneurysm. The systems further comprise first and second delivery catheters which can be utilized for aligning each of the first and second filling structures properly with the right and left iliacs and the infrarenal aorta as they are being deployed, filled, and hardened.

[0031] The systems of the present invention for treating abdominal aortic aneurysms and other bifurcated lumens will typically include at least a first and a second scaffold, one for each of the tubular lumens defined by the first and second double-walled filling structures, respectively. The scaffolds will generally be the same as those described for the single filling structure embodiments, except that in some instances portions of the scaffold which extend into the adjacent blood vessel may be modified in order to enhance their ability to conform to each other. For example, the ends of the scaffolds may be modified to have D-shaped cross-sections so that when they are expanded, the flat surfaces of the D-shaped sections will engage each other to provide for a very full coverage of the area of the blood vessel. In other instances, the ends of the scaffolds which extend into the blood vessel may be formed into C-shaped structures which are expanded together to form a single generally continuous ring structure engaging the blood vessel wall.

#### BRIEF DESCRIPTION OF THE DRAWINGS

#### DETAILED DESCRIPTION OF THE INVENTION

[0041] A system 10 constructed in accordance with the principles of the present invention for delivering a double-walled filling structure 12 to an aneurysm includes the filling structure and a delivery catheter 14 having an expandable element 16, typically an inflatable balloon, at its distal end. The catheter 14 will comprise a guidewire lumen 18, a balloon inflation lumen (not illustrated) or other structure for expanding other expandable components, and a filling tube 20 for delivering a filling medium or material to an internal space 22 of the double-walled filling structure 12. The internal space 22 is defined between an outer wall 24 and inner wall 26 of the filling structure. Upon inflation with the filling material or medium, the outer wall will expand radially outwardly, as shown in broken line, as will the inner wall 26, also shown in broken line. Expansion of the inner wall 26 defines an internal lumen 28. The expandable balloon or other structure 16 will be expandable to support an inner surface of the lumen 28, as also in broken line in Fig. 1.

[0042] Referring now to Fig. 2, and the various internal and external surfaces may be shaped, coated, treated, or otherwise modified, to provide for a number of particular features in accordance with the principles of the present invention. For example, the outer wall 24 may be shaped to have rings, stipples, or other surface features which are typically formed into the material of the structure at the time of molding, vapor deposition, or other manufacturing process. The outer surface may also be coated with materials 28 which can be adhesives, drugs, active substances, fibers, flocking, foams, or a variety of other materials. In most cases, such surface features or modifications will be intended to enhance sealing or attachment of the outer wall 24 to the inner surface of the aneurysm being treated.

[0043] The inner surface 30 of the filling volume 22 may also be modified by providing features, coatings, surface roughening, or a variety of other modifications. The purpose of such internal features is typically to enhance adherence of the walls to the filling material or medium as the medium is cured or otherwise hardened. In some instances, materials may be coated on all or a portion of the inside surface 30 to induce or catalyze hardening of the filling material as it is being introduced.

[0044] The double-walled filling structure 12 will typically comprise at least one valve 40 to permit the introduction of the filling material or medium into the internal volume 22. As illustrated, the valve 40 may be a simple flap valve. Other more complex ball valves, and other one-way valve structures may be provided. In other instances, two-way valve structures may be provided to permit both filling and selective emptying of the internal volume 22. In other instances, the filling tube may comprise a needle or other filling structure to pass through the valve 40 to permit both filling and removal of filling medium.

[0045] As illustrated in Fig. 2, the wall structure of the double-walled filling structure may be a single layer, typically molded or otherwise conventionally formed. The wall structures may also be more complex, as illustrated for example, Figs 3A-3C. Fig. 3A shows a multi-layered wall comprising layers 42, 43 and 44. It will be appreciated that such multiple layer structure can provide for increased strength, puncture resistance, variations in compliance and/or flexibility, differences in resistance to degradation, and the like. As shown in Fig. 3B, a single wall or multiple wall structure can be reinforced by braid, coils, or other metal or non-polymeric reinforcement layers or structures. As shown in Fig. 3C, the external surface 24 of the wall may be covered with drugs, fibers, protrusions, holes, active agents or other substances for a variety of purposes.

[0046] Referring now to Fig. 4, the anatomy of an infrarenal abdominal aortic aneurysm comprises the thoracic aorta (TA) having renal arteries (RA) at its distal end above the iliac arteries (IA). The abdominal aortic aneurysm (AAA) typically forms between the renal arteries (RA) and the iliac arteries (IA) and may have regions of mural thrombus (T) over portions of its inner surface (S).

[0047] Referring to Figs. 5A-5D, the treatment system 10 of Fig. 1 may be utilized to treat the complex geometry of the transmural abdominal aortic aneurysm (AAA) of Fig. 4 by first positioning the delivery catheter 14 to place the double-walled filling structure 12 (in its unfilled configuration) generally across the aneurysm from the region of the aorta beneath the

renal arteries (RA) to a region over the iliac arteries (IA), as best seen Fig. 5A. Usually, the delivery catheter 14 will be introduced over a guidewire (GW) through a puncture in the patient's groin accessing the iliac artery by the Seldinger technique.

[0048] After the double-walled filling structure 12 is properly positioned, a hardenable inflation medium is introduced into the internal space 22 filling of the inner space 22 expands the outer wall 24 of the structure outwardly so that it conforms to the inner surface (S) of the aneurismal space.

[0049] Before, during, or after filling of the double-walled filling structure 12 with inflation medium, as illustrated in Fig. 5B, the balloon 16 or other expansible structure will also be inflated or expanded to open the tubular lumen defined by the interior of the inner wall 26. In a preferred embodiment, the balloon 16 will be generally compliant, typically having a maximum diameter of width which is at or slightly larger than the desired tubular lumen diameter or width through the deployed filling structure 12. The filling structure 12, in contrast, may be partially or completely formed from a generally non-compliant material, thus allowing the non-compliant balloon or other expansible structure 16 to fully open the tubular lumen and conform the ends of the lumens to the aorta and iliac walls, as illustrated in Fig. 5C. A lower or proximal end 50 of the tubular lumen will be flared to a larger diameter so that it can accommodate the openings into both of the iliac arteries (IA) as illustrated. Thus, it will be preferred to utilize a filling structure 12 geometry which has been chosen or fabricated to match the particular patient geometry being treated. It will also be preferable to use a balloon 16 or other expansible structure which will be shaped to preferentially open the lower proximal end 50 of the tubular lumen to a larger diameter than the upper or distal end 52.

[0050] After the filling material has been introduced to the filling structure 12, typically through the filling tube 20, the fluid filling material must be cured or otherwise hardened to provide for the permanent implant having a generally fixed structure which will remain in place in the particular aneurismal geometry. Methods for curing or hardening the filling material will depend on the nature of the filling material. For example, certain polymers may be cured by the application of energy, such as heat energy or ultraviolet light. Other polymers may be cured when exposed to body temperature, oxygen, or other conditions which cause polymerization of the fluid filling material. Still others may be mixed immediately prior to use and simply cure after a fixed time, typically minutes.

[0051] In accordance with the present invention, at least one scaffold will be placed into the tubular lumen defined by the inner wall 26. As illustrated in Fig. 5D, the scaffold may be a short, stent-like structure which may be implanted in the upper proximal opening 52 of the tubular lumen of the filling structure 12 in order to help anchor the upper end of the structure and prevent intrusion of blood into the region between the outer wall 24 and the inner surface S of the aneurysm and to generally improve the transition from the aorta into the tubular lumen. The stent-like structure 60 may comprise any conventional stent, graft, or other expandable luminal support structure known in the arts.

[0052] As shown in Fig. 5E, an alternative stent structure 64 may span the entire length from the aortic end of the filling structure 12 to the iliac end. Stent structure 64 could also comprise any conventional stent or graft structure, typically being an expandable metal frame optionally covered with a membrane to form a graft.

[0053] As shown in Fig. 5F, a further alternative stent structure 66 may extend fully through the filling structure and into the thoracic aorta TA, often covering the renal arteries RA. The portion of the stent 66 which extends through the filling structure 12 will often be covered with a membrane or other protective material so that the stent is actually a graft within the filling structure. A portion of the stent structure within the thoracic aorta TA, however, will preferably be left open to permit blood flow into the renal arteries RA.

[0054] As shown in Fig. 5G, two or more stent structures 68 may be implanted within the tubular lumen of the filling structure 12. As illustrated, the relatively short stent structures 68 are positioned at the aortic side and the iliac side of the filling structure. They could be positioned elsewhere, and the stent segments could be longer and extend into either the aorta either or both of the iliacs.

[0055] As shown in Fig. 5H, two or more stent structures 70 may be deployed within the tubular lumen of the filling structure 12 in an overlapping manner. By overlapping the stent segment 70, the overall length of the stent structure can be adjusted, e.g., to fully cover the renal arteries if that is desired, or in other instances to avoid covering the renal arteries if that is what is desired.

[0056] The stents, grafts, and other scaffold structures will often be delivered using separate delivery catheters (not shown) of the type commonly used to intravascularly deliver stents and grafts. The scaffold delivery catheters may comprise balloons or other expansion elements for expanding malleable scaffolds *in situ*. Alternatively, the delivery catheters

could comprise tubular sheaths for covering and constraining self-expanding scaffolds prior to release within the tubular lumens of the filling structures. Systems could also deliver the scaffold(s) simultaneously with the filling structure(s), often on a common delivery catheter system.

5   **[0057]** In a particular and preferred aspect of the present invention, a pair of double-walled filling structures will be used to treat infrarenal abdominal aortic aneurysms, instead of only a single filling structure as illustrated in Figs. 5A-5C. A system comprising such a pair of filling structures is illustrated in Fig. 6 which includes a first filling structure 112 and a second filling structure 212. Each of the filling structures 112 and 212 are mounted on  
10   delivery catheters 114 and 214, respectively. The components of the filling structures 112 and 212 and delivery catheters 114 and 214 are generally the same as those described previously with respect to the single filling structure system 10 of Fig. 1. Corresponding parts of each of the fillings systems 112 and 212 will be given identical numbers with either the 100 base number or 200 base number. A principal difference between the filling  
15   structures 112 and 212, on the one hand, and the filling structure 12 of Fig. 1 is that the pair of filling structures will generally have asymmetric configurations which are meant to be positioned adjacent to each other within the aneurismal space and to in combination fill that space, as will be described with specific reference to Fig. 7A-7F below.

**[0058]** In treating an infrarenal abdominal aortic aneurysm using the pair of filling  
20   structures 112 and 212 illustrated in Fig. 6, a pair of guidewires (GW) will first be introduced, one from each of the iliac arteries (IA). As illustrated in Fig. 7A. The first delivery catheter 114 will then be positioned over one of the guidewires to position the double-walled filling structure 112 across the aortic aneurysm (AAA), as illustrated in Fig. 7B. The second delivery catheter 214 is then delivered over the other guidewire (GW) to  
25   position the second filling structure 212 adjacent to the first structure 112 within the aneurysm (AAA), as illustrated in Fig. 7C. Typically, one of the filling structures and associated balloons will be expanded first, followed by the other of the filling structures and balloon, as illustrated in Fig. 7D where the filling structure 112 and balloon 116 are inflated to fill generally half of the aneurismal volume, as illustrated in Fig. 7D. Filling can generally  
30   be carried out as described above with the one filling structure embodiment, except of course that the filling structure 112 will be expanded to occupy only about one-half of the aneurismal volume. After the first filling structure 112 has been filled, the second filling structure 212 may be filled, as illustrated in Fig. 7E. In other protocols the two filling

structures may be filled simultaneously. The upper ends of the balloons 116 and 216 will conform the tubular lumens of the filling structures against the walls of the aorta as well as against each other, while the lower ends of the balloons 116 and 216 will conform the tubular lumens into the respective iliac (IA).

5 [0059] After filling the filling structures 112 and 212 as illustrated in Fig. 7E, the filling materials or medium will be cured or otherwise hardened, and the delivery catheters 114 and 214 removed, respectively. The hardened filling structures will then provide a pair of tubular lumens opening from the aorta beneath the renal arteries to the right and left iliac arteries, as shown in broken line in Fig. 7. The ability of the filling structures 112 and 212 to  
10 conform to the inner surface (S) of the aneurysm, as shown in Fig. 7F, helps the structures to remain immobilized within the aneurysm with little or no migration. Immobilization of the filling structures 112 and 114 may be further enhanced by providing any of the surface features described above in connection with the embodiments of Fig. 2.

[0060] As with the single filling structure embodiments described previously, the double  
15 filling structure embodiments will include at least one separate scaffold deployed within each of the tubular blood flow lumens. The scaffolds will generally be stent-like or graft-like vascular structures and will be deployed within the tubular lumens using balloon or other expansion catheters (in the case of malleable or balloon-expandable scaffolds) or using constraining sheaths (in the case of self-expanding scaffolds).

20 [0061] Referring in particular to Fig. 7G, the first scaffold 250 may be placed in the tubular lumen of the first filling structure 112 while a second scaffold 252 may be placed in the tubular lumen of the second filling structure 212. As illustrated, the scaffolds are stent-like structures which extend into the iliac arteries IA at the lower end of the filling structures.

[0062] Referring now to Fig. 7H, first and second scaffolds 254 and 256 may extend  
25 upwardly on the aortic side of the first and second filling structures 112 and 212. When the separate stent or other scaffold structures extend into the thoracic aorta TA, it will usually be desirable that they be expanded so that they conform to each other along a plane or region of contact. For example, as shown in Fig. 7H-1, the upper ends of the scaffolds 254 and 256 may be formed preferentially to have D-shaped cross-sections when expanded. Thus, flat  
30 faces 258 and 260 will engage each other with the remaining portion of the stent conforming to the inner wall of the aorta. In this way, most of the cross-sectional area of the aorta will be covered with the stent, thus enhancing blood flow through the filling structures.

Alternatively, as shown in Fig. 7H-2, the upper regions of the scaffolds 254 and 256 may be cut or otherwise modified to form open C-shaped cross-sections. In such cases, the expanded scaffolds can be arranged so that the C-shaped regions engage each other to form a continuous ring structure about the inner wall of the aorta. The open C-shaped regions will transition into a tubular region as the scaffolds enter the tubular lumens of the filling structures 112 and 212. In either of these embodiments, the scaffolds 254 and 256 may be partially or fully covered with a membrane or graft material, as described above in connection with other embodiments, particularly where such coverings extend partially or fully over the portion of the scaffold that extends into the adjacent blood vessel.

[0063] Referring now to Fig. 7I, scaffolds 260 and 264 may be implanted into the tubular lumens of the first filling structure 112 and second filling structure 212, respectively. The scaffold 260 includes an extension 268 at its lower end which is covered with a membrane or other material to form a graft region within the scaffold. This graft region 268 passes through an aneurysmal region within the iliac artery IA, thus allowing the structure to treat the iliac aneurysm as well as the aortic aneurysm. Optionally, a clip 269 or other fastening device, link, or tether, could be provided to connect the upper ends of the scaffolds 260 and 264 in the filling structures 112 and 212. By attaching the ends of the scaffolds, the distal ends of the filling structures will be stabilized and the risk of scaffold migration will be reduced.

[0064] As shown in Fig. 7J, a first scaffold 270 and second scaffold 274 are placed in the first filling structure and second filling structure 112 and 212, respectively. The scaffold 270 has a membrane covering as metal frame through the entire length of the tubular lumen of the filling structure. In addition, the covered structure extends into the iliac artery. The portion of the first scaffold 270 extending into the aorta, however, is not covered to allow blood flows through the open mesh region of the metal frame. Similarly, the second scaffold 274 has an open mesh region in the aorta and a covered, graft-like region passing through the tubular lumen of the second filling structure 212. The second scaffold 274, however, does not extend into the iliac artery IA.

[0065] Various modifications of the protocols described above will be within the scope of the present invention. For example, while the scaffolds have been shown as being delivered after deployment of the filling structure(s), it will also be possible to deliver the scaffolds simultaneously with or prior to deployment of the filling structures. For example, the scaffolds could be delivered on the same delivery catheter(s) used to deliver and/or shape the

filling structures. The scaffolds could then be expanded at the same time as filling the filling structure or even prior to filling the filling structure.

[0066] While the above is a complete description of the preferred embodiments of the invention, various alternatives, modifications, and equivalents may be used. Therefore, the  
5 above description should not be taken as limiting the scope of the invention which is defined by the appended claims.

WHAT IS CLAIMED IS:

- 1                   1.     A system for treating an aneurysm in a blood vessel, said system  
2 comprising:  
3                   at least a first double-walled filling structure having an outer wall and an inner  
4 wall, wherein said filling structure is adapted to be filled with a hardenable fluid filling  
5 medium so that the outer wall conforms to the inside surface of the aneurysm and the inner  
6 wall forms a first generally tubular lumen to provide a path for blood flow; and  
7                   at least a first scaffold separate from the first filling structure which can be  
8 expanded within at least a portion of the tubular lumen of the filling structure.
- 1                   2.     A system as in claim 1, wherein the scaffold extends over substantially  
2 the entire length of the generally tubular lumen.
- 1                   3.     A system as in claim 1, wherein the scaffold extends outwardly from at  
2 least one end of the generally tubular lumen into the adjacent blood vessel.
- 1                   4.     A system as in claim 3, wherein the scaffold extends outwardly from  
2 both ends of the generally tubular lumen into the adjacent blood vessel.
- 1                   5.     A system as in claim 1, comprising at least two scaffolds for placing in  
2 the tubular lumen.
- 1                   6.     A system as in claim 5, wherein the scaffolds are adapted to be placed  
2 in series.
- 1                   7.     A system as in claim 5, wherein the scaffolds are adapted to be  
2 overlapped with one another and/or attached to each other.
- 1                   8.     A system as in claim 1, wherein the scaffold is elastic and adapted to  
2 self-expand from a constrained configuration to a deployed configuration.
- 1                   9.     A system as in claim 8, wherein the scaffold is a self-expanding mesh.
- 1                   10.    A system as in claim 1, wherein the scaffold is malleable and adapted  
2 to be balloon expanded from a narrow diameter configuration to a deployed configuration.
- 1                   11.    A system as in claim 1, wherein the scaffold comprises a metal frame.

1                   12.     A system as in claim 11, wherein at least a portion of the metal frame  
2 is covered with a membrane.

1                   13.     A system as in claim 12, wherein a portion of the scaffold which is to  
2 be positioned with the tubular lumen is covered with the membrane and a portion which is to  
3 extend beyond the tubular lumen is not covered.

1                   14.     A system as in claim 1, wherein at least an outer wall of the filling  
2 structure is formed from a compliant material.

1                   15.     A system as in claim 1, wherein substantially the entire filling structure  
2 is formed from a compliant material.

1                   16.     A system as in claim 1, wherein at least a portion of an exterior surface  
2 of the filling structure is modified to enhance sealing or tissue ingrowth.

1                   17.     A system as in claim 16, wherein the surface modification comprises  
2 surface roughening, a foam layer, fibers, flocking, stipples, or drug coating.

1                   18.     A system as in claim 1, wherein at least a portion of an interior surface  
2 of the filling structure is modified to enhance hardening of the structure.

1                   19.     A system as in claim 18, wherein the surface modification comprises  
2 surface roughening, rings, stipples, flocking, a foam layer, or fibers.

1                   20.     A system as in claim 1, further comprising a delivery catheter having  
2 an expandable tubular support which can be positioned within the first tubular lumen to carry  
3 the double-walled filling structure.

1                   21.     A system as in claim 20, wherein the expandable tubular support  
2 extends upstream and downstream from the double-walled filling structure so that tubular  
3 support aligns and conforms each end of the filling structure with the blood vessel.

1                   22.     A system as in claim 20, wherein the tubular support comprises an  
2 inflatable support balloon having a non-compliant structure.

1                   23.     A system as in claim 22, wherein the tubular support comprises a  
2 mechanical structure expandable to one or more fixed diameters.

1                   24.     A system as in claim 1, further comprising:

2                   a second double-walled filling structure having an outer wall and an inner  
3 wall, wherein said second double-walled filling structure is adapted to be placed adjacent to  
4 the first filling structure in the aneurysm and to be filled with a hardenable fluid filling  
5 medium so that the outer wall conforms to the inside surface of the aneurysm and to the first  
6 filling structure and forms a second generally tubular lumen to provide a bath for blood flow;  
7 and

8                   at least a second scaffold separate from the first scaffold and the filling  
9 structures which can be expanded within at least a portion of the second tubular lumen of the  
10 second filling structure.

1                   25.     A system as in claim 24, wherein the second scaffold extends over  
2 substantially the entire length of the second generally tubular lumen.

1                   26.     A system as in claim 24, wherein the second scaffold extends  
2 outwardly from at least one end of the second generally tubular lumen into the adjacent blood  
3 vessel.

1                   27.     A system as in claim 24, wherein the second scaffold extends  
2 outwardly from both ends of the second generally tubular lumen.

1                   28.     A system as in claim 24, comprising at least two scaffolds for placing  
2 in the tubular lumen of the second double-walled filling structure.

1                   29.     A system as in claim 28, wherein the scaffolds are adapted to be placed  
2 in series.

1                   30.     A system as in claim 28, wherein the scaffolds are adapted to be  
2 overlapped with one another.

1                   31.     A system as in claim 24, wherein the second scaffold is elastic and  
2 adapted to self-expand from a constrained configuration to a deployed configuration.

1                   32.     A system as in claim 24, wherein the second scaffold is malleable and  
2 adapted to be balloon expanded from a narrow diameter configuration to a deployed  
3 configuration.

1                   33.     A system as in claim 24, wherein the second scaffold is a self-  
2     expanding mesh.

1                   34.     A system as in claim 24, wherein the second scaffold comprises a  
2     metal frame.

1                   35.     A system as in claim 34, wherein at least a portion of the metal frame  
2     is covered with a membrane.

1                   36.     A system as in claim 35, wherein a portion of the second scaffold  
2     which is to be positioned with the tubular lumen is covered with the membrane and a portion  
3     which is to extend beyond the tubular lumen is not covered.

1                   37.     A system as in claim 24, wherein respective ends of the first and  
2     second scaffolds extend outwardly in parallel in at least one direction from their respective  
3     tubular lumens into the adjacent blood vessel.

1                   38.     A system as in claim 37, wherein said respective ends have  
2     complementary shapes to together conform to the wall of the adjacent blood vessel.

1                   39.     A system as in claim 38, wherein said respective ends have mating  
2     D-shaped cross-sections.

1                   40.     A system as in claim 38, wherein said respective ends have mating  
2     C-shaped cross-sections.

1                   41.     A system as in claim 24, wherein further comprising;  
2                   a first delivery catheter having an expandable support which can be positioned  
3     within the tubular lumen of the first double-walled filling structure; and  
4                   a second delivery catheter having an expandable support which can be  
5     positioned within the tubular lumen of the second double-walled filling structure.

1                   42.     A system as in claim 41, wherein the expandable support on each  
2     delivery catheter extends upstream and downstream from the double-walled filling structure  
3     so that tubular support aligns and conforms each end of the filling structure with the iliac and  
4     aorta.

- 1                   43.     A system as in claim 24, wherein at least an outer wall of each filling  
2 structure is formed from a compliant material.
- 1                   44.     A system as in claim 24, wherein substantially the entire filling  
2 structure is formed from a non-compliant material.
- 1                   45.     A system as in claim 24, wherein the expandable support comprises an  
2 inflatable support balloon having a compliant structure.
- 1                   46.     A method as in claim 24, wherein the expandable support on each  
2 delivery catheter comprises a mechanical structure expandable to one or more fixed diameter.
- 1                   47.     A system as in claim 24, wherein at least a portion of an exterior  
2 surface is modified to enhance sealing or tissue ingrowth.
- 1                   48.     A system as in claim 47, wherein the surface modification comprises  
2 roughening, a foam layer, fibers, or drug coating.
- 1                   49.     A system as in claim 24, further comprising a filling material including  
2 a flowable polymer which is curable *in situ*.
- 1                   50.     A system as in claim 24, wherein the polymer comprises a  
2 polyurethane, a polyethylene glycol, a collagen.
- 1                   51.     A system as in claim 24, wherein the filling material has a specific  
2 gravity in the range from 0.1 to 5 when hardened.
- 1                   52.     A system as in claim 24, wherein the filling material comprises a two-  
2 part curable material which hardens after mixing.
- 1                   53.     A method for treating an aneurysm, said method comprising:  
2                   positioning at least a first double-walled filling structure across the aneurysm;  
3                   filling the at least first filling structure with a fluid filling medium so that an  
4 outer wall conforms to an inside surface of the aneurysm and an inner wall forms a first  
5 generally tubular lumen to provide a first blood flow path across the aneurysm; and  
6                   placing at least a first scaffold within at least a portion of the first generally  
7 tubular lumen.

- 1                    54.     A method as in claim 53, further comprising hardening the filling  
2 material in the first filling structure.
- 1                    55.     A method as in claim 53, wherein placing the scaffold comprises  
2 releasing an elastic scaffold structure within the tubular lumen after the filling structure has  
3 been filled.
- 1                    56.     A method as in claim 53, wherein placing the scaffold comprises  
2 inflating an expansion member within a malleable scaffold structure after the filling structure  
3 has been filled.
- 1                    57.     A method as in claim 55, wherein the scaffold is placed after the filling  
2 of the filling structure but before the material has hardened.
- 1                    58.     A method as in claim 55, wherein the scaffold is placed after the filling  
2 material has hardened.
- 1                    59.     A method as in claim 53, wherein the scaffold is placed to extend over  
2 substantially the entire length of the generally tubular lumen.
- 1                    60.     A method as in claim 53, wherein the scaffold is placed to extend  
2 outwardly from at least one end of the generally tubular lumen into the adjacent blood vessel.
- 1                    61.     A method as in claim 53, wherein the scaffold is placed to extend  
2 outwardly from both ends of the generally tubular lumen into the adjacent blood vessel.
- 1                    62.     A method as in claim 53, comprising placing at least two scaffolds in  
2 the tubular lumen.
- 1                    63.     A method as in claim 62, wherein the scaffolds are placed in series.
- 1                    64.     A method as in claim 62, wherein the scaffolds are overlapped with  
2 one another.
- 1                    65.     A method as in claim 53, wherein the scaffold is elastic and released  
2 from a constraint to self-expand from a constrained configuration to a deployed  
3 configuration.

- 1                   66.     A method as in claim 65, wherein the scaffold is a self-expanding  
2 mesh.
- 1                   67.     A method as in claim 53, wherein the scaffold is malleable and balloon  
2 expanded from a narrow diameter configuration to a deployed configuration.
- 1                   68.     A method as in claim 53, wherein the scaffold comprises a metal  
2 frame.
- 1                   69.     A method as in claim 68, wherein at least a portion of the metal frame  
2 is covered with a membrane.
- 1                   70.     A method as in claim 69, wherein a portion of the scaffold which is to  
2 be positioned with the tubular lumen is covered with the membrane and a portion which is to  
3 extend beyond the tubular lumen is not covered.
- 1                   71.     A method as in claim 53, further comprising supporting the first  
2 tubular lumen while and/or after the filling structure is being filled.
- 1                   72.     A method as in claim 71, wherein the tubular lumen support extends  
2 upstream and downstream from the double-walled filling structure so that tubular support  
3 aligns and conforms each end of the filling structure with the blood vessel.
- 1                   73.     A method as in claim 53, wherein at least an outer wall of the filling  
2 structure is formed from a non-compliant material.
- 1                   74.     A method as in claim 73, wherein substantially the entire filling  
2 structure is formed from a non-compliant material.
- 1                   75.     A method as in claim 73, wherein the tubular support comprises an  
2 inflatable support balloon having a compliant structure.
- 1                   76.     A method as in claim 73, wherein the tubular support comprises a  
2 mechanical structure expandable to one or more fixed diameters.
- 1                   77.     A method as in claim 53, wherein the filling structure is filled with  
2 fluid filling medium at filling pressure and the inflatable support balloon is inflated at an  
3 inflation pressure which is great than the filling pressure.

1                   78.     A method as in claim 77, wherein the filling pressure is in the range  
2     from 100 mm Hg to 1000 mm Hg and the inflation pressure is in the range from 200 mm Hg  
3     to 5000 mm Hg.

1                   79.     A method as in claim 53, further comprising positioning an anchor or  
2     sealing element of at least one opening from the tubular lumen of the filling structure to a  
3     lumen of the blood vessel.

1                   80.     A method as in claim 79, further comprising positioning an anchor or  
2     sealing element at each opening.

1                   81.     A method as in claim 53, wherein the filling material comprises a  
2     flowable polymer which is curable *in situ*.

1                   82.     A method as in claim 81, wherein the polymer comprises a  
2     polyurethane, a polyethylene glycol, a collagen.

1                   83.     A method as in claim 81, wherein the filling material has a density in  
2     the range from 0.1 gm/cc to 5 gm/cc when hardened.

1                   84.     A method as in claim 81, wherein the filling material comprises a two-  
2     part curable material which hardened after mixing.

1                   85.     A method as in claim 53, further comprising:  
2                   positioning at least a second double-walled filling structure across the  
3     aneurysm adjacent to the first double-walled filling structure;  
4                   filling the at least second double-walled filling structure with a fluid filling  
5     medium so that an outer wall of the second filling structure conforms to both the inside of the  
6     aneurysm and the outer wall of the first filling structure and that an inner wall of the second  
7     filling structure forms a second generally tubular lumen to provide a second blood flow path  
8     across the aneurysm; and

9                   placing at least a second scaffold with at least a portion of the second  
10     generally tubular lumen.

1                   86.     A method as in claim 85, further comprising hardening the filling  
2     material in the second filling structure.

1           87.    A method as in claim 86, comprising:  
2                supporting the tubular lumen of the first filling structure while an/or after the  
3 first filling structure is being filled; and  
4                supporting the tubular lumen of the second filling structure while and/or after  
5 the second filling structure is being filled.

1           88.    A method as in claim 87, further comprising:  
2                removing support from the tubular lumen of the first filling structure after the  
3 filling material has hardened; and  
4                removing support from the tubular lumen of the second filling structure after  
5 the filling material has hardened.

1           89.    A method as in claim 87, wherein the tubular lumen support extends  
2 upstream and downstream from each double-walled filling structure so that tubular support  
3 aligns and conforms each end of the filling structure with the iliac and aorta.

1           90.    A method as in claim 87, wherein at least an outer wall of the filling  
2 structure is formed from a non-compliant material.

1           91.    A method as in claim 90, wherein substantially the entire filling  
2 structure is formed from a non-compliant material.

1           92.    A method as in claim 87, wherein the tubular support comprises an  
2 inflatable balloon having a compliant structure.

1           93.    A method as in claim 87, wherein the tubular support comprises a  
2 mechanical structure expandable to one or more fixed diameters.

1           94.    A method as in claim 87, wherein each filling structure is filled with  
2 fluid filling medium at filling pressure and each inflatable support balloon is inflated at an  
3 inflation pressure which is great than the filling pressure.

1           95.    A method as in claim 94, wherein the filling pressure is in the range  
2 from 100 mm Hg to 1000 mm Hg and the inflation pressure is in the range from 200 mm Hg  
3 to 5000 mm Hg.

1                   96.     A method as in claim 87, wherein the scaffold provides an anchor or  
2     sealing element of at least one opening from the tubular lumen of at least one of the filling  
3     structures to a lumen of the iliac or aorta.

1                   97.     A method as in claim 96, wherein the scaffold provides an anchor or  
2     sealing element at each opening.

1                   98.     A method as in claim 87, wherein the filling material comprises a  
2     flowable polymer which is curable *in situ*.

1                   99.     A method as in claim 98, wherein the polymer comprises a  
2     polyurethane, a polyethylene glycol, a collagen.

1                   100.    A method as in claim 98, wherein the filling material has a specific  
2     gravity in the range from 0.1 to 5 when hardened.

1                   101.    A method as in claim 98, wherein the filling material comprises a two-  
2     part curable material which hardens after mixing.

1                   102.    A system as in claim 98, further comprising a filling material including  
2     a flowable polymer which is curable *in situ*.

1                   103.    A system as in claim 98, wherein the polymer comprises a  
2     polyurethane, a polyethylene glycol, a collagen.

1                   104.    A system as in claim 53, wherein the respective ends of the first and  
2     second scaffolds extend outwardly in parallel in at least one direction from their respective  
3     tubular lumens into the adjacent blood vessel.

1                   105.    A system as in claim 104, wherein said respective ends have  
2     complementary shapes to together conform to the wall of the adjacent blood vessel.

1                   106.    A system as in claim 105, wherein said respective ends have mating  
2     D-shaped cross-section.

1                   107.    A system as in claim 105, wherein said respective ends have mating  
2     C-shaped cross-sections.
