Disposable absorbent article comprising two different types of polymer particles

Superabsorbent polymer particles are used in a liquid-absorbent core of a disposable body fluid absorbent garment. The polymer particles comprise first polymer particles having a relatively high water-absorption speed and second polymer particles having a water-absorption speed lower than that of the first polymer particles by 10 seconds or more. The second polymer particles are integrally bonded to the first polymer particles.
Description

The present invention relates to a disposable body fluid absorbent garment such as a disposable diaper or a sanitary napkin.

It is well known in a garment of this type to cover a liquid-absorbent core comprising fluff pulp and superabsorptive polymer particles with a liquid-permeable sheet. It is also well known that superabsorbent polymer particles tend to become viscous and agglomerate together into gel blocks, if they absorb water. Such gel blocks prevent body fluids from permeating into the liquid-absorbent core and may cause the body fluids to leak, when the gel blocks are formed in the top surface area of the core.

One of measures to prevent the superabsorbent polymer particles from forming such gel blocks is to disperse the superabsorbent polymer particles in such water-absorptive fibrous material as fluff pulp which is used with the polymer particles so that the individual particles are adequately spaced apart one from another. However, such a measure is not practical due to a limitation imposed upon a size of the liquid-absorbent core. There may occur a case in which the disposed polymer particles cannot be used so effectively as to achieve an effect expected for the liquid-absorbent core. To overcome such a problem, it may be contemplated to mix polymer particles having a relatively high water-absorption speed with polymer particles having a relatively low water-absorption speed. For example, the polymer particles of these two types which are different in their water-absorption speeds are mixed together so that a mixture thereof may form a single layer in a liquid-absorbent core. However, it may be difficult to mix uniformly them if the polymer particles of these two types are of significantly different particle sizes. It is further contemplated to arrange that the polymer particles of these two types may form separate layers in liquid-absorbent core without being mixed together wherein the polymer particles having a relatively low water-absorption speed form an upper layer while the polymer particles having a relatively high water-absorption speed form a lower layer and fluff pulp is disposed between these two layers. However, such an arrangement would make the manufacturing process for a liquid-absorbent core complex because the polymer particles must be fed twice in the process.

In view of problems as have been described above, it is a principal object of the invention to prevent superabsorbent polymer particles from easily forming gel blocks within a liquid-absorbent core.

The object set forth above is achieved, according to the invention, by a disposable body fluid absorbent garment having a liquid-absorbent core comprising a mixture of water-absorptive fibrous material and superabsorbent polymer particles, and a liquid-permeable sheet at least partially covering the liquid-absorbent core, the disposable body fluid absorbent garment being characterized by that:

the polymer particles comprise first polymer particles having a water-absorption time shorter than 10 seconds as measured under the conditions as given below and second polymer particles having a water-absorption time longer than that of the first polymer particles by 10 seconds or more and integrally bonded to the first polymer particles;

measurement conditions for water-absorption time

(1) 25ml of 0.9% saline water is poured into a 50ml beaker and stirred at 500r.p.m. by a magnetic stirrer equipped with a rotary element having a diameter of 7mm and a length of 20mm; and
(2) 1g of superabsorbent polymer particles is poured into the beaker during stirring and a time required by these polymer particles to absorb the whole quantity of the saline water is determined by the eye.

Fig. 1 is a perspective view showing a disposable diaper as an embodiment of the invention as partially broken away;

Fig. 2 is a sectional view taken along line II-II in Fig. 1; and

Fig. 3 is a schematic diagram illustrating superabsorbent polymer particles.

Details of the invention will be more fully understood from the following description of a disposable diaper as a specific embodiment of the invention made with respect to the accompanying drawings.

A diaper 1 shown by Fig. 1 in a perspective view as partially broken away comprises a liquid-permeable topsheet 2, a liquid-impermeable backsheet 3, and a liquid-absorbent core 4 disposed between these two sheets 2, 3. Portions of these two sheets 2, 3 extending outward beyond the whole peripheral edge of the core 4 are put one upon the other and water-tightly bonded to each other. The diaper 1 is longitudinally composed of a front region (front body) 6, a rear region (rear body) 7 and a crotch region 8 extending between these regions 6, 7. Adjacent the upper edge 9 of the rear region 7 and transversely opposite side edges 10 of the crotch region 8, an elastic member 13 for a waist-opening and elastic members 14 for a pair of leg-openings are respectively disposed between the top- and backsheets 2, 3 and bonded under an elastically stretched condition to an inner surface of at least one of these two sheets 2, 3. Transversely opposite side edges 16 of the rear region 7 are provided with tape fasteners 15.

Fig. 2 is a sectional view taken along line II-II in Fig. 1. As shown, the core 4 comprises an upper layer 21, a lower layer 22 and a tissue paper 23 covering these upper and lower layers 21, 22. The upper layer 21 has a basis weight of 190g/m² and comprises a mixture of fluff pulp 25 of 90% by weight and thermoplastic fibers 26 of 10% by weight. The lower layer 22 has a basis weight...
of 430g/m² and comprises fluff pulp of 50% by weight, thermoplastic fibers 26 of 5% by weight and superabsorbent polymer particles 27 of 45% by weight. In the lower layer the polymer particles 27 are distributed between a top layer 28A and a bottom layer 28B. These two layers 28A, 28B respectively comprise a mixture of the fluff pulp 25 and the thermoplastic fibers 25. The upper and lower layers 21, 22 are heat-treated so that the thermoplastic fibers 25 may be integrally heat-bonded within each layer 21, 22 as well as between the two layers 21, 22 and thereby prevent a shape-loss of the core 4 as a whole. The tissue paper 23 serves to protect such components as the fluff pulp 25 against scattering and at the same time to facilitate handling of the core 4 during a manufacturing process of the diaper. It should be understood that the tissue paper 23 may be eliminated from the core 4, unless it is necessary.

The superabsorbent polymer particles 27 schematically illustrated by Fig. 3 in an enlarged scale comprise first polymer particles 27A of a relatively high water-absorption speed and a relatively small particle size and the second polymer particles 27B bonded to the polymer particles 27A and having a relatively low water-absorption speed and a relatively large particle size. The particle sizes of the polymer particles 27 are in a range of 0.2 - 0.5 mm. The first polymer particles 27A and the second polymer particles 27B should have a differential water-absorption time of 10 or more seconds and the first polymer particles 27A should have a water-absorption time shorter than 10 seconds as measured under the conditions as will be described below.

Measurement conditions for water-absorption time:

(1) 25ml of 0.9% saline water is poured into a 50ml beaker and stirred at 500r.p.m. by a magnetic stirrer equipped with a rotary element having a diameter of 7 mm and a length of 20 mm.
(2) 1 g of superabsorbent polymer particles is poured into the beaker during stirring and a time required by the polymer particles to absorb the whole quantity of the saline water is visually determined.

The polymer particles 27 as a complex of the first and second polymer particles 27A, 27B can be obtained by, for example, adding the second polymer particles 27B to a polymerizing system of water-soluble ethylenic unsaturated monomer to produce the first polymer particles 27A.

A process to produce the polymer particles 27 will be more specifically described. The water-soluble ethylenic unsaturated monomers include nonionic monomers such as (metha)acrylic acid, 2-(metha)acrylamide-2-methylpropane sulfonic acid and alkali salts thereof, (metha)acrylamide, N, N-dimethylacrylamide, 2-hydroxyethyl(metha)acrylate, and N-methylol(metha)acrylamide, and amino-group containing unsaturated monomers such as diethylaminomethyl(metha)acrylate, diethylaminopropyl(metha)acrylate and diethylaminopropyl(metha)acrylamide and quaternary compounds thereof. Two or more of these water-soluble ethylenic unsaturated monomers may be used in the form of a mixture. It should be understood that (metha)acrylic acid and derivatives thereof may be replaced by acrylic acid and derivatives thereof. These water-soluble ethylenic unsaturated monomers are usually used in a state of aqueous solution.

For the water-soluble ethylenic unsaturated monomers a reversed-phase suspension polymerization is applied and suitable hydrocarbon is used as solvent. The hydrocarbon solvent includes aliphatic hydrocarbon solvent, alicyclic hydrocarbon solvent and aromatic hydrocarbon solvent. The aliphatic hydrocarbon solvent includes n-hexane, n-heptane and ligoine. The alicyclic hydrocarbon solvent includes cyclopentane, methycyclopentane, cyclohexane and methylcyclohexane. The aromatic hydrocarbon solvent includes benzene, toluene and xylene. These hydrocarbon solvents may be used in the form of a mixture of two or more hydrocarbon solvents.

During the reversed-phase suspension polymerization, the hydrocarbon solvent is added with surfactant or macromolecule protective colloid. These surfactant and macromolecule protective colloid may be used together. The surfactant may be selected from those which allow for reversed-phase suspension polymerization of water-soluble ethylenic unsaturated monomer, for example, nonionic surfactants such as sorbitan fatty acid ester, polyglycerin fatty acid ester, sucrose fatty acid ester, sorbitol fatty acid ester, polyoxyethylenealkylphenylether. The macromolecule protective colloids include ethylcellulose, ethylhydroxyethylcellulose, oxidation-modified polyethylene, maleic anhydride-modified polyethylene, maleic anhydride-modified polybutadiene, maleic anhydride-modified EPDM (ethylene propylene diene terpolymer).

These nonionic surfactant and macromolecule protective colloid may be used with anionic surfactant such as salts of fatty acid, alkylbenzenesulfonic acid, alkylmethyltaurine, polyoxyethylenealkylphenylether sulfonic acid ester or polyoxyethylenealkylsulfonic acid. Effective quantity of surfactant and/or macromolecule protective colloid is usually 0.1 - 5% by weight and preferably 0.2 - 3% by weight of aqueous solution of water-soluble ethylenic unsaturated monomer.

For polymerization of water-soluble ethylenic unsaturated monomer, suitable crosslinking agents may be used. Such crosslinking agents include: di- or tri-(metha)acrylic acid esters of polyols such as ethylene glycol, propylene glycol, trimethylolpropane, glycerin-polyoxyethylene glycol, polyoxypropylene glycol, polyglycerin; or unsaturated polyesters obtained from reaction of these polyols with unsaturated acids such as maleic acid and fumaric acid; bis-acrylamides such as N,N'-methylenebisacrylamide; di- or tri-(metha)acrylic acid esters obtained from reaction of polyepoxide with
water-absorption speed are not easily swollen and provide among the swollen first polymer particles with voids allowing the body fluids to be pass through. The body fluids come into contact with the first polymer particles underlying below the voids and are absorbed by the particles. In this manner, the presence of the second polymer particles is effective to prevent the layered superabsorbent polymer particles from forming gel blocks in the surface zone of the lower layer. Thus, the first polymer particles underlying the surface zone can be effectively used.

Claims

1. A disposable body fluid absorbent garment having a liquid-absorbent core comprising a mixture of water-absorbent fibrous material and superabsorbent polymer particles and a liquid-permeable sheet at least partially covering the liquid-absorbent core, the disposable body fluid absorbent garment being characterized by that:

   - the polymer particles comprise first polymer particles having water-absorption time shorter than 10 seconds as measured under the conditions as given below and second polymer particles having water-absorption time longer that of said first polymer particles by 10 seconds or more and integrally bonded to the first polymer particles;

measurement conditions for water-absorption time:

   (1) 25ml of 0.9% saline water is poured into a 50ml beaker and stirred at 500r.p.m. by a magnetic stirrer equipped with a rotary element having a diameter of 7mm and a length of 20mm; and
   (2) 1g of superabsorbent polymer particles is poured into the beaker during stirring and a time required by the polymer particles to absorb the whole quantity of the saline water is determined by the eye.
