SYNTHESIS METHOD AND INTERMEDIATES USEFUL IN THE PREPARATION OF PYRROLOBENZODIAZEPINES

The present invention relates to methods useful in the synthesis of pyrrolobenzodiazepines (PBDs), and in particular of pyrrolobenzodiazepines having C2 substitution and N10 protection.

Background to the invention

PBDs are of the general structure:

C2-substituted compounds

In WO 2004/043963, a diverse range cytotoxic compounds having an aryl group at the C2 position, for example:

were disclosed. The synthesis of these compounds was achieved via the following intermediate:

whose synthesis was described in detail in WO 00/12508. An analogous dimeric intermediate is disclosed in WO 2010/010347.

WO 2005/085251 discloses the synthesis of a number cytotoxic compounds having an aromatic substituent or unsaturated substituent at C2 from the intermediate:

2

These intermediates are very useful for synthesis C2 substituted PBD compounds having a N10-C11 imine bond, or compounds readily derivable from these, e.g. bisulphite versions,
5 as in WO 2010/010347. The N10 protecting groups used are not labile under the conditions used to add the C2 aryl substituents, for example, in a Suzuki coupling using a palladium catalyst.

10 The C2-aryl or unsaturated group is installed by forming a C2-enol triflate followed by a palladium catalyzed Suzuki reaction. It is advantageous to add the C2 aryl or unsaturated substituents as late as possible in the synthesis by the methods described above, as this means a diverse range of substituents can be added to a single 'core'.

15 However, there are compounds of interest where the protecting groups or linkers desired at N10 are labile under either the triflation conditions (e.g. substituted *p*-aminobenzyl or *p*-hydroxybenzyl carbamates) or palladium catalysis (e.g. Alloc), see below.

20 Such groups are preferably introduced at a point in the synthesis of the PBD before the B-ring is formed by cyclisation. Otherwise, these groups would need to be added via a chloroformate to the PBD's imine bond. In addition, the cyclisation of PBD is best carried out where the pro-N10 nitrogen has only a single hydrogen attached, i.e., where the protecting group is already in place.

25 WO 2005/085259 discloses PBD compounds useful as intermediates in the synthesis of PBD dimers. These intermediates have a hydroxy group at the C7 or C8 position.

Disclosure of the invention

30 The present inventors have developed a key intermediate for the production of C2 substituted PBDs having a palladium sensitive N10 protecting group, and a method for its synthesis.

3

In a first aspect, the present invention comprises a compound of formula I:

wherein:

R^7 is selected from: OR^A , where R^A is selected from C_{1-4} saturated alkyl, optionally substituted by phenyl, which phenyl may bear a chloro substituent, pyridyl and furanyl; chloro; NH_2 ; and $-CH_2-O-C(=O)Me$;

R^8 is $OProt^O$, where $Prot^O$ is a silicon-based oxygen protecting group orthogonal to R^C ;

R^9 is selected from H, methyl and methoxy;

R^S is selected from CF_3 , $(CF_2)_3CF_3$, CH_3 and

and

R^C is selected from:

(i) $-C(=O)-OR^{C1}$, where R^{C1} is a saturated C_{1-4} alkyl group;

(ii) $-CH_2-O-C(=O)R^{C2}$, where R^{C2} is methyl or phenyl;

(iii) $-CH_2-O-Si-(R^{Si1})(R^{Si2})(R^{Si3})$, where R^{Si1} , R^{Si2} , R^{Si3} are independently selected from a C_{1-6} saturated alkyl group and a phenyl group; and

(iv) $-C(-YR^{C3})(-YR^{C4})$ where each Y is independently O or S, and where R^{C3} and R^{C4} are independently a saturated C_{1-4} alkyl group, or together form a C_{2-3} alkylene.

The compound of formula I is preferably substantially free of any of the corresponding compound of formula IB:

wherein R^7 , R^8 , R^9 and R^C are as defined in the compound of formula I. "Substantially free" means that there is less than 5% by weight of the compound of formula IB compared to the amount of the compounds of formula I. More preferably, there is less than 1% or 0.1% by weight of the compound of formula IB.

In a second aspect, the present invention provides a method of synthesising a compound of formula I as defined in the first aspect of the invention from a compound of formula II:

5 wherein R⁷, R⁸, R⁹ and R^C are as defined in the first aspect;
comprising treating II with the appropriate anhydride and anhydrous 2,6-lutidine or
anhydrous 2,6-^tBu-pyridine at a temperature of -35°C or lower in a dry organic solvent
under an inert atmosphere.

10 The following reaction has been previously disclosed (Kang, G-D., *et al.*, **Chem. Commun.**, 2003, 1680-1689):

This reaction was carried out using (trifluoromethanesulfonyl)aminopyridine at -78°C, which followed treatment with either LDA (lithium diethylamide) or NaHMDS (sodium hexamethyldisilazide). The method involving LDA gave a mixture of A to B in the ratio 1:4, whilst the NHDMS method gave only B.

Compounds of formula I can be converted into N10 protected PBD compounds by the following steps.

5

A.

where R^2 is selected from:

- (i) an optionally substituted C_{5-20} aryl group;
- 5 (ii) an optionally substituted C_{1-5} alkyl group (including a C_{2-5} alkenyl group and a C_{2-5} alkynyl group); and
- (iii) H.

10 These conversions are carried using palladium catalysis, and include: Suzuki couplings with an appropriate boron derivative; Heck coupling with alkenes, including acrylamides and acrylates; Stille couplings with organo tin reagents, such as alkyl tin reagents; Sonagishira couplings with alkynes; and hydride transfer using triethyl silanes.

15 The conversion where R^2 is an optionally substituted C_{5-20} aryl group (a Suzuki coupling) is carried out by palladium catalysed cross coupling of I with the appropriate aryl boron derivative. The palladium catalyst may be any suitable catalyst, for example $Pd(PPh_3)_4$, $Pd(OCOCH_3)_2$, $PdCl_2$, or $Pd(dba)_3$.

20 Suzuki couplings may also be used to cross couple alkyl boron species. The Gibbs group has reported (Mu, Y.Q and Gibbs, R.A, *Tetrahedron Letters*, 36, 5669-5672, **1995**) the successful conversion of an enol triflate to a methyl substituted alkene (using a $Pd(PHCN)_2Cl_2$ catalyst):

25 Deng's group successfully achieved the coupling of a cyclopropylboronic acid and a cyclic triflate using a $Pd(MeCN)_2Cl_2$ catalyst (Yao and Deng, *J. Org. Chem.* **2000**, 65, 1609).

Cyclopropyl MIDA boronates have been successfully coupled to aryl chlorides under slow release conditions; intact MIDA boronates are resistant to standard Suzuki conditions due to their pyramidal hybridization (Knapp *et al. J. Am. Chem. Soc.*, **2009**, *131*, 6961-6963). These conditions are also applicable to enoltriflates.

Knapp *et al. J. Am. Chem. Soc.*, **2009**, *131*, 6961-6963

Molander (Molander and Ito *Org. Lett.*, **2001**, *3*, 393-396) has developed potassium alkyltrifluoroborates as Suzuki coupling partners for aryl and vinyl triflates.

Suzuki couplings may also be used to cross couple alkenyl boron species. Suzuki and co workers have demonstrated (Suzuki *et al.*, Synlett **1990**, 221; *J Org Chem* **1993**, *58*, 2201) the coupling of cyclic triflates and benzodioxoleborole compounds

7

Alkenyl Boronic acids have also been coupled to PBD C-ring enoltriflates (WO2005/085251):

5

The pinacol esters of acrylylboronic acids are known:

10

and are likely to be useful in Suzuki coupling reactions.

PBD enol triflates have been successfully coupled to acrylamides and acrylates under Heck conditions (Chen et al., *Bioorg. Med. Chem. Lett.* 14, (2004), 1547-1549):

8

Alkynyl tin reagents have been coupled under Stille conditions to PBD triflates (Tiberghien et al., *Bioorg. Med. Chem. Lett.* 14, (2004), 5041-5044):

5

Alkynyl substituents can also be installed via the Sonogishira reaction (Nishihara et al *J. Org. Chem.*, 2000, 65, 1780-1787) :

10

Other palladium catalysed reactions include the use trialkylindium reagents in cross-coupling reactions (Perez et al. *Org. Lett.* 1999, 1, 1267-1269) :

15

The approach can also be used to introduce aryl, vinyl and alkynyl groups.

Palladium catalysis can also be used in hydride transfer reactions to generate alkenes with triethylsilanes (Cramer *et al. Angew. Chem. Int. Ed.* **2005**, *44*, 820-822):

where R^{D} is selected from:

- 10 (ii) $-\text{CH}_2-\text{O}-\text{C}(=\text{O})\text{R}^{\text{C}2}$, where $\text{R}^{\text{C}2}$ is methyl or phenyl;
 (iii) $-\text{CH}_2-\text{O}-\text{Si}-(\text{R}^{\text{Si}1})(\text{R}^{\text{Si}2})(\text{R}^{\text{Si}3})$, where $\text{R}^{\text{Si}1}$, $\text{R}^{\text{Si}2}$, $\text{R}^{\text{Si}3}$ are independently selected from a C_{1-6} saturated alkyl group and a phenyl group; and
 (iv) $-\text{C}(-\text{YR}^{\text{C}3})(-\text{YR}^{\text{C}4})$ where each Y is independently O or S, and where $\text{R}^{\text{C}3}$ and $\text{R}^{\text{C}4}$ are independently a saturated C_{1-4} alkyl group, or together form a C_{2-3} alkylene,
 15 and R^{D} is orthogonal to Prot^{O} .

If R^{C} is $-\text{CH}_2-\text{O}-\text{C}(=\text{O})\text{R}^{\text{C}2}$ or $-\text{CH}_2-\text{O}-\text{Si}-(\text{R}^{\text{Si}1})(\text{R}^{\text{Si}2})(\text{R}^{\text{Si}3})$ then the conversion of **III** to **IV** is by reduction of the nitro group.

- 20 If R^{C} is $-\text{C}(=\text{O})-\text{OR}^{\text{C}1}$, then the conversion of **III** to **IV** is achieved by first reducing of the ester and reprotection as an acetate or silyl ether. The reduction can be achieved by standard means, for example with LiAlH_4 , LiBH_4 or NaBH_4 , but preferably LiBH_4 .
 Reprotection as an acetate can be achieved, for example, by reaction with acetyl chloride;
 reprotection as a benzoate can be achieved, for example, by reaction with benzoyl
 25 chloride; reprotection as a silyl ether can be achieved, for example, by reaction with the appropriate silyl chloride. The reduction of the nitro group is then carried out as described above.

C:

where R^{10} is a carbamate-based nitrogen protecting group, which is palladium-labile and/or labile under the conditions used to add the group:

, or contains a moiety which is palladium-labile and/or is labile under the conditions used to add the group:

, i.e. liable to be removed in the presence of palladium or under the conditions used to add the group:

. In this application these protecting groups are classified as 'simple' and 'complex'.

Conversion of **IV** to **V** is usually achieved by reaction of **IV** with triphosgene to obtain the isocyanate followed by reaction with R^{10} -OH. This approach is described in WO 2005/023814.

Alternatively, simple nitrogen protecting groups can also be introduced as a chloroformate, fluoroformate or azidoformate. The more complex nitrogen protecting groups, as well as the simple nitrogen protecting groups, can be introduced as O-succinamide carbonates, O-pentafluorophenyl carbonates and O-nitrophenyl carbonates.

11

D:

When R^D is $-\text{CH}_2\text{-O-C(=O)Me}$, the conversion of **V** to **VI** may be achieved by initial removal of the acetate protecting group, with potassium carbonate in aqueous methanol, or with lithium triethylborohydride. Oxidation with Dess-Martin periodinane (or alternatively TPAP/NMO, TFAA/DMSO, $\text{SO}_3\cdot\text{Pyridine}$ complex/DMSO, PDC, PCC, BAIB/TEMPO or under Swern conditions) affords the ring closed product.

When R^D is $-\text{CH}_2\text{-O-C(=O)Ph}$, the conversion of **V** to **VI** may be achieved by initial removal of the benzoate protecting group, with sodium hydroxide in aqueous methanol, followed by oxidation as described above.

When R^D is $-\text{CH}_2\text{-O-Si-(R}^{\text{Si1}}\text{)(R}^{\text{Si2}}\text{)(R}^{\text{Si3}}\text{)}$, the conversion of **V** to **VI** may be achieved by initial removal of the silyl ether protecting group, for example using TBAF in THF, acetic acid in aqueous THF, CsF in DMF or HF in pyridine, followed by oxidation as described above. The removal conditions must be selected such that they do not remove Prot^{O} .

When R^D is $-\text{C}(\text{-YR}^{\text{C3}}\text{)(-YR}^{\text{C4}}\text{)}$, the conversion of **V** to **VI** may be achieved by removal of the acetal or thioacetal protecting groups, respectively with acid or reaction with Hg (II) salts – the cyclisation occurs spontaneously

E:

wherein R^E is selected from: O-C_{1-2} alkyl; $\text{O-Si-(R}^{\text{Si1}}\text{)(R}^{\text{Si2}}\text{)(R}^{\text{Si3}}\text{)}$, where R^{Si1} , R^{Si2} , R^{Si3} are as defined above; $\text{O-CH}_2\text{OCH}_3$ (OMOM), $\text{O-CH}_2\text{OC}_2\text{H}_4\text{OCH}_3$ (OMEM), OC_5H_{10} (THP). Prot^{O}

12

needs to be orthogonal to R^E , and therefore R^E needs to be selected with this in mind. In some embodiments, R^E may also be $OC(=O)Me$.

OH is converted to R^E by conventional methods. For example, when R^E is O- C_{1-2} alkyl, the conversion may be carried out by reaction with C_{1-2} alkyl-I and silver oxide or $(C_{1-2}$ alkyl) $_3O^+BF_4^-$ in DCM in the presence of DIPEA. When R^E is OMOM or OMEM, the conversion may be carried out by reaction with the appropriate chloride in DCM in the presence of DIPEA. When R^E is THP, the conversion may be carried out by reaction with DHP in the presence of acid. When R^E is O-Si- $(R^{Si1})(R^{Si2})(R^{Si3})$, the conversion may be carried out by reaction with the appropriate triflate in the presence of 2,6-lutidine.

F:

Deprotection of the phenolic hydroxy group is carried out by, for example, lithium acetate. The removal conditions must be selected such that they do not remove R^E .

G:

where Hal is selected from I, Cl and Br, and n is from 1 to 12.

- 5 The term 'substantially free of' means that there is less than 5% by weight of the compound of the undesired compound (i.e., B version) compared to the amount of the desired compound. More preferably, there is less than 1% or 0.1% by weight.

The present invention also provides

In the above further aspects of the present invention, the defined substituent groups in the intermediate compounds are the same as those in the final products where designated in the same way (e.g. R⁹ remains the same throughout the method of synthesis).

In the above further aspects of the invention, the methods may also comprise the intermediate steps as set out above.

Definitions

- 25 *Silicon-based oxygen protecting groups*

Silicon-based oxygen protecting groups are well known in the art. A large number of suitable groups are described on pages 113 to 148 of Greene, T.W. and Wuts, G.M.,

Protective Groups in Organic Synthesis, 3rd Edition, John Wiley & Sons, Inc., 1999.

The groups form silyl ethers with the oxygen to which they are attached, and are generally of the formula:

Orthogonal

- 10 A first protecting group which is orthogonal to a second protecting group means that the first protecting group can be removed from a compound bearing both protecting groups without the second protecting group being removed.

As discussed above, R^{D} is orthogonal to Prot^{O} , and Prot^{O} is orthogonal to R^{E} .

These groups may be or may comprise elements of the groups described, for example, in WO 00/12507. These carbamate-based nitrogen protecting groups may include elements that are sensitive to palladium or the conditions used to add the group:

In one embodiment, the carbamate-based nitrogen protecting group is a linker for connection to an antibody, R^L :

where the asterisk indicates the point of attachment to the N10 position, G^1 is a functional group to form a connection to a cell binding agent, L^1 is a cleavable linker, L^2 is a covalent

bond or together with -OC(=O)- forms a self-immolative linker.

In one embodiment, the protecting group R^L is removable from the N10 position thereby to provide the imine or carbinoalmine form of the PBD.

5

L^1 is preferably a cleavable linker, and may be referred to as a trigger for activation of the linker for cleavage.

10

The nature of L^1 and L^2 , where present, can vary widely. These groups are chosen on the basis of their cleavage characteristics, which may be dictated by the conditions at the site to which the PBD molecule is delivered, for example as an antibody drug conjugate. Those linkers that are cleaved by the action of enzymes are preferred, although linkers that are cleavable by changes in pH (e.g. acid or base labile), temperature or upon irradiation (e.g. photolabile) may also be used. Linkers that are cleavable under reducing or oxidising

15

conditions may also find use in the present invention.

L^1 may comprise a contiguous sequence of amino acids. The amino acid sequence may be the target substrate for enzymatic cleavage, thereby allowing release of R^{10} from the N10 position.

20

In one embodiment, the L^1 is cleavable by the action of an enzyme. In one embodiment, the enzyme is an esterase or a peptidase.

In one embodiment, L^2 is present and together with C(=O)O forms a self-immolative linker.

25

In one embodiment, where L^1 is cleavable by the action of an enzyme and L^2 is present, the enzyme cleaves the bond between L^1 and L^2 .

L^1 and L^2 may be connected by a bond selected from:

30

-C(=O)NH-,

-C(=O)O-,

-NHC(=O)-,

-OC(=O)-,

-OC(=O)O-,

35

-NHC(=O)O-,

-OC(=O)NH-, and
-NHC(=O)NH-.

5 An amino group of L^1 that connects to L^2 may be the N-terminus of an amino acid or may be derived from an amino group of an amino acid side chain, for example a lysine amino acid side chain.

An carboxyl group of L^1 that connects to L^2 may be the C-terminus of an amino acid or may be derived from a carboxyl group of an amino acid side chain, for example a glutamic acid amino acid side chain.

10 A hydroxy group of L^1 that connects to L^2 may be derived from a hydroxy group of an amino acid side chain, for example a serine amino acid side chain.

In one embodiment, -C(=O)O- and L^2 together form the group:

15 where the asterisk indicates the point of attachment to the N10 position, the wavy line indicates the point of attachment to the linker L^1 , Y is -N(H)-, -O-, -C(=O)N(H)- or -C(=O)O-, and n is 0 to 3. The phenylene ring is optionally substituted with one, two or three substituents as described herein. In one embodiment, the phenylene group is optionally substituted with halo, NO₂, R or OR.

20

In one embodiment, Y is NH.

In one embodiment, n is 0 or 1. Preferably, n is 0.

25 Where Y is NH and n is 0, the self-immolative linker may be referred to as a p-aminobenzylcarbonyl linker (PABC).

The self-immolative linker will allow for release of the protected compound when a remote site is activated, proceeding along the lines shown below (for n=0):

21

where L^* is the activated form of the remaining portion of the linker. These groups have the advantage of separating the site of activation from the compound being protected. As described above, the phenylene group may be optionally substituted.

5

In one embodiment described herein, the group L^* is a linker L^1 as described herein, which may include a dipeptide group.

In another embodiment, $-C(=O)O-$ and L^2 together form a group selected from:

10

In one embodiment, the phenylene ring having the Y substituent is optionally substituted and the phenylene ring not having the Y substituent is unsubstituted. In one embodiment, the phenylene ring having the Y substituent is unsubstituted and the phenylene ring not having the Y substituent is optionally substituted.

15

In another embodiment, $-C(=O)O-$ and L^2 together form a group selected from:

22

5 In one embodiment, D is N.

In one embodiment, D is CH.

In one embodiment, E is O or S.

In one embodiment, F is CH.

10 In a preferred embodiment, the linker is a cathepsin labile linker.

In one embodiment, L¹ comprises a dipeptide. The dipeptide may be represented as -NH-X₁-X₂-CO-, where -NH- and -CO- represent the N- and C-terminals of the amino acid groups X₁ and X₂ respectively. The amino acids in the dipeptide may be any combination of natural amino acids. Where the linker is a cathepsin labile linker, the dipeptide may be the site of action for cathepsin-mediated cleavage.

15 Additionally, for those amino acids groups having carboxyl or amino side chain functionality, for example Glu and Lys respectively, CO and NH may represent that side chain functionality.

In one embodiment, the group -X₁-X₂- in dipeptide, -NH-X₁-X₂-CO-, is selected from:

-Phe-Lys-,

-Val-Ala-,

25 -Val-Lys-,

where Cit is citrulline.

Preferably, the group $-X_1-X_2-$ in dipeptide, $-NH-X_1-X_2-CO-$, is selected from:

Other dipeptide combinations may be used, including those described by Dubowchik et al. (*Bioconjugate Chem.* **2002**, 13, 855-869).

15

In one embodiment, the amino acid side chain is chemically protected, where appropriate. The side chain protecting group may be a group as discussed below in relation to the group R^L . The present inventors have established that protected amino acid sequences are cleavable by enzymes. For example, the present inventors have established that a

20 dipeptide sequence comprising a Boc side chain-protected Lys residue is cleavable by cathepsin.

Protecting groups for the side chains of amino acids are well known in the art and are described in the Novabiochem Catalog. Additional protecting group strategies are set out

25 in *Protective Groups in Organic Synthesis*, Greene and Wuts.

Possible side chain protecting groups are shown below for those amino acids having reactive side chain functionality:

- Arg: Z, Mtr, Tos;
- 30 Asn: Trt, Xan;
- Asp: Bzl, t-Bu;
- Cys: Acn, Bzl, Bzl-OMe, Bzl-Me, Trt;

10 In one embodiment, the dipeptide is used in combination with a self-immolative linker. The self-immolative linker may be connected to $-X_2-$.

In one embodiment, the dipeptide is used in combination with a self-immolative linker. The self-immolative linker may be connected to $-X_2-$.

15

Where a self-immolative linker is present, $-X_2-$ is connected directly to the self-immolative linker. Preferably the group $-X_2-CO-$ is connected to Y, where Y is NH, thereby forming the group $-X_2-CO-NH-$.

20 $-NH-X_1-$ is connected directly to A. A may comprise the functionality $-CO-$ thereby to form an amide link with $-X_1-$.

In one embodiment, L^1 and L^2 together with $-OC(=O)-$ comprise the group $NH-X_1-X_2-CO-PABC-$. The PABC group is connected directly to the N10 position.

25 Preferably, the self-immolative linker and the dipeptide together form the group $-NH-Phe-Lys-CO-NH-PABC-$, which is illustrated below:

where the asterisk indicates the point of attachment to the N10 position, and the wavy line indicates the point of attachment to the remaining portion of the linker L^1 or the

point of attachment to A. Preferably, the wavy line indicates the point of attachment to A. The side chain of the Lys amino acid may be protected, for example, with Boc, Fmoc, or Alloc, as described above.

- 5 Alternatively, the self-immolative linker and the dipeptide together form the group -NH-Val-Ala-CO-NH-PABC-, which is illustrated below:

where the asterisk and the wavy line are as defined above.

- 10 In one embodiment, L^2 together with $-OC(=O)-$ represents:

- where the asterisk indicates the point of attachment to the N10 position, the wavy line indicates the point of attachment to L^1 , n is 0 to 3, Y is a covalent bond or a functional group, and E is an activatable group, for example by enzymatic action or light, thereby to generate a self-immolative unit. The phenylene ring is optionally further substituted with one, two or three substituents as described herein. In one embodiment, the phenylene group is optionally further substituted with halo, NO_2 , R or OR . Preferably n is 0 or 1, most preferably 0.
- 20 E is selected such that the group is susceptible to activation, e.g. by light or by the action of an enzyme. E may be $-NO_2$ or glucuronic acid. The former may be susceptible to the action of a nitroreductase, the latter to the action of a β -glucuronidase.

- 25 In this embodiment, the self-immolative linker will allow for release of the protected compound when E is activated, proceeding along the lines shown below (for $n=0$):

26

where the asterisk indicates the point of attachment to the N10 position, E^* is the activated form of E, and Y is as described above. These groups have the advantage of separating the site of activation from the compound being protected. As described above, the phenylene group may be optionally further substituted.

The group Y may be a covalent bond to L^1 .

The group Y may be a functional group selected from:

-C(=O)-

-NH-

-O-

-NHC(=O)O-,

-OC(=O)NH-,

-NHC(=O)NH-,

-NHC(=O)NH,

-C(=O)NHC(=O)-, and

-S-.

Where L^1 is a dipeptide, it is preferred that Y is -NH- or -C(=O)-, thereby to form an amide bond between L^1 and Y. In this embodiment, the dipeptide sequence need not be a substrate for an enzymatic activity.

In another embodiment, G is intended to form a spacer group that is suitable for indirectly connecting L^1 to a cell binding agent.

L¹ and G¹ may be connected by a bond selected from:

-C(=O)NH-,
 -C(=O)O-,
 -NHC(=O)-,
 -OC(=O)-,
 -OC(=O)O-,
 -NHC(=O)O-,
 -OC(=O)NH-, and
 -NHC(=O)NH-.

In one embodiment, the functional group G¹ is or comprises an amino, carboxylic acid, hydroxy, thiol, or maleimide group for reaction with an appropriate group on the cell binding agent. In a preferred embodiment, G¹ comprises a maleimide group.

In one embodiment, the group G¹ is an alkyl maleimide group. This group is suitable for reaction with thiol groups, particularly cysteine thiol groups, present in the cell binding agent, for example present in an antibody.

In one embodiment, the group G¹ is:

where the asterisk indicates the point of attachment to L¹ and n is 0 to 6. In one embodiment, n is 5.

In one embodiment, the group G¹ is:

-SH,
 -C(=O)CH₂X, where X is Cl, Br or I,
 -CHO,
 -NHNH₂
 -C≡CH, and
 -N₃ (azide).

In particular embodiments, the maleimide group may be replaced by -C(=O)CH₂I. Thus, in particular embodiments, the group G¹ is:

where the asterisk indicates the point of attachment to L¹ and n is 0 to 6. In one embodiment, n is 0.

In particular embodiments, the group G¹ is:

where the asterisk indicates the point of attachment to L¹, m is 0 to 30. In a preferred embodiment, m is 0 to 10, 1 to 7, preferably 3 to 7, and most preferably 3 or 7.

In particular embodiments, the group G¹ is:

where the asterisk indicates the point of attachment to L¹, m is 0 to 30. In a preferred embodiment, m is 0 to 10, 1 to 7, preferably 3 to 7, and most preferably 3 or 7.

In one embodiment, where L¹ is present, G¹ is -NH₂, -NHMe, -COOH, -OH or -SH.

In one embodiment, where L¹ is present, G¹ is -NH₂ or -NHMe. Either group may be the N-terminal of an L¹ amino acid sequence.

In one embodiment, where L^1 is present, G^1 is $-NH_2$, and L^1 is an amino acid sequence $-X_1-X_2-$, as defined above in relation to R^{10} .

- 5 In one embodiment, where L^1 is present, G^1 is $COOH$. This group may be the C-terminal of an L^1 amino acid sequence.

In one embodiment, where L^1 is present, G^1 is OH .

In one embodiment, where L^1 is present, G^1 is SH .

10

The group G^1 may be convertible from one functional group to another. In one embodiment, where L^1 is present, G^1 is $-NH_2$. This group is convertible to another group G^1 comprising a maleimide group. For example, the group $-NH_2$ may be reacted with an acid or an activated acid (e.g. N-succinimide forms) of those G^1 groups comprising maleimide shown above.

15

The group G^1 may therefore be converted to a functional group that is more appropriate for reaction with a cell binding agent.

- 20 In other embodiments, R^1 is a group that is a precursor to the linker that is provided with a functional group.

As noted above, in one embodiment, where L^1 is present, G^1 is $-NH_2$, $-NHMe$, $-COOH$, $-OH$ or $-SH$. In a further embodiment, these groups are provided in a chemically protected form.

- 25 The chemically protected form is therefore a precursor to the linker that is provided with a functional group.

- In one embodiment, G^1 is $-NH_2$ in a chemically protected form. The group may be protected with a carbamate protecting group. The carbamate protecting group may be selected from the group consisting of:

30

Alloc, Fmoc, Boc, Troc, Teoc, Cbz and PNZ.

Preferably, where G^1 is $-NH_2$, it is protected with an Alloc or Fmoc group.

In one embodiment, particularly where the compound is a dimer, the nitrogen protecting group for one of the PBD units is a group R^L and the nitrogen protecting group for the other of the PBD units is a capping group, R^{Cap} :

5 where the asterisk indicates the point of attachment to the N10 position, G^2 is a terminating group, L^3 is a covalent bond or a cleavable linker L^1 , L^2 is a covalent bond or together with $OC(=O)$ forms a self-immolative linker.

10 The protecting group R^C is removable from the N10 position thereby to provide the imine or carbinolamine form of the PBD. The term “capping group” is used to indicate that R^C is prevented from reacting with a cell binding agent, such as an antibody. Instead, the group R^L is for connection to a cell binding agent.

15 Where L^3 and L^2 are both covalent bonds, G^2 and $-OC(=O)-$ together form a carbamate protecting group such as shown above in Table 1.

L^1 is as defined above in relation to R^L .

L^2 is as defined above in relation to R^L .

20 In one embodiment L^3 is a cleavable linker L^1 , and L^2 , together with $OC(=O)$, forms a self-immolative linker. In this embodiment, G^2 is Ac (acetyl) or Moc, or a carbamate protecting group selected from:

Alloc, Fmoc, Boc, Troc, Teoc, Psec, Cbz and PNZ.

25 In one embodiment L^3 is a cleavable linker L^1 , and L^2 , together with $OC(=O)$, forms a self-immolative linker. In this embodiment, G^2 together with $OC(=O)$, is a carbamate protecting group selected from Table 1 above.

30 G^2 is different to G^1 . Furthermore, it is preferred that G^1 is removable under conditions that do not remove G^1 .

Certain compounds may exist in one or more particular geometric, optical, enantiomeric, diastereomeric, epimeric, atropic, stereoisomeric, tautomeric, conformational, or anomeric forms, including but not limited to, cis- and trans-forms; E- and Z-forms; c-, t-, and r- forms; endo- and exo-forms; R-, S-, and meso-forms; D- and L-forms; d- and l-forms; (+) and (-) forms; keto-, enol-, and enolate-forms; syn- and anti-forms; synclinal- and anticlinal-forms; α - and β -forms; axial and equatorial forms; boat-, chair-, twist-, envelope-, and halfchair-forms; and combinations thereof, hereinafter collectively referred to as “isomers” (or “isomeric forms”).

Preferably compounds of formula **VI** have the following stereochemistry at the C11 position:

Note that, except as discussed below for tautomeric forms, specifically excluded from the term “isomers”, as used herein, are structural (or constitutional) isomers (i.e. isomers which differ in the connections between atoms rather than merely by the position of atoms in space). For example, a reference to a methoxy group, $-\text{OCH}_3$, is not to be construed as a reference to its structural isomer, a hydroxymethyl group, $-\text{CH}_2\text{OH}$. Similarly, a reference to ortho-chlorophenyl is not to be construed as a reference to its structural isomer, meta-chlorophenyl. However, a reference to a class of structures may well include structurally isomeric forms falling within that class (e.g. C_{1-7} alkyl includes n-propyl and iso-propyl; butyl includes n-, iso-, sec-, and tert-butyl; methoxyphenyl includes ortho-, meta-, and para-methoxyphenyl).

The above exclusion does not pertain to tautomeric forms, for example, keto-, enol-, and enolate-forms, as in, for example, the following tautomeric pairs: keto/enol (illustrated below), imine/enamine, amide/imino alcohol, amidine/amidine, nitroso/oxime, thioketone/enethiol, N-nitroso/hydroxyazo, and nitro/aci-nitro.

47

Note that specifically included in the term “isomer” are compounds with one or more isotopic substitutions. For example, H may be in any isotopic form, including ¹H, ²H (D), and ³H (T); C may be in any isotopic form, including ¹²C, ¹³C, and ¹⁴C; O may be in any isotopic form, including ¹⁶O and ¹⁸O; and the like.

Unless otherwise specified, a reference to a particular compound includes all such isomeric forms, including (wholly or partially) racemic and other mixtures thereof. Methods for the preparation (e.g. asymmetric synthesis) and separation (e.g. fractional crystallisation and chromatographic means) of such isomeric forms are either known in the art or are readily obtained by adapting the methods taught herein, or known methods, in a known manner.

Unless otherwise specified, a reference to a particular compound also includes ionic, salt, solvate, and protected forms of thereof, for example, as discussed below.

It may be convenient or desirable to prepare, purify, and/or handle a corresponding salt of the active compound, for example, a pharmaceutically-acceptable salt. Examples of pharmaceutically acceptable salts are discussed in Berge, *et al.*, *J. Pharm. Sci.*, **66**, 1-19 (1977).

For example, if the compound is anionic, or has a functional group which may be anionic (e.g. -COOH may be -COO⁻), then a salt may be formed with a suitable cation. Examples of suitable inorganic cations include, but are not limited to, alkali metal ions such as Na⁺ and K⁺, alkaline earth cations such as Ca²⁺ and Mg²⁺, and other cations such as Al³⁺. Examples of suitable organic cations include, but are not limited to, ammonium ion (i.e. NH₄⁺) and substituted ammonium ions (e.g. NH₃R⁺, NH₂R₂⁺, NHR₃⁺, NR₄⁺). Examples of some suitable substituted ammonium ions are those derived from: ethylamine, diethylamine, dicyclohexylamine, triethylamine, butylamine, ethylenediamine, ethanolamine, diethanolamine, piperazine, benzylamine, phenylbenzylamine, choline, meglumine, and tromethamine, as well as amino acids, such as lysine and arginine. An example of a common quaternary ammonium ion is N(CH₃)₄⁺.

If the compound is cationic, or has a functional group which may be cationic (e.g. $-\text{NH}_2$ may be $-\text{NH}_3^+$), then a salt may be formed with a suitable anion. Examples of suitable inorganic anions include, but are not limited to, those derived from the following inorganic acids:
5 hydrochloric, hydrobromic, hydroiodic, sulfuric, sulfurous, nitric, nitrous, phosphoric, and phosphorous.

Examples of suitable organic anions include, but are not limited to, those derived from the following organic acids: 2-acetoxybenzoic, acetic, ascorbic, aspartic, benzoic, camphorsulfonic, cinnamic, citric, edetic, ethanedisulfonic, ethanesulfonic, fumaric,
10 glucheptonic, gluconic, glutamic, glycolic, hydroxymaleic, hydroxynaphthalene carboxylic, isethionic, lactic, lactobionic, lauric, maleic, malic, methanesulfonic, mucic, oleic, oxalic, palmitic, pantoic, pantothenic, phenylacetic, phenylsulfonic, propionic, pyruvic, salicylic, stearic, succinic, sulfanilic, tartaric, toluenesulfonic, and valeric. Examples of suitable polymeric organic anions include, but are not limited to, those derived from the following
15 polymeric acids: tannic acid, carboxymethyl cellulose.

It may be convenient or desirable to prepare, purify, and/or handle a corresponding solvate of the active compound. The term "solvate" is used herein in the conventional sense to refer to a complex of solute (e.g. active compound, salt of active compound) and solvent. If
20 the solvent is water, the solvate may be conveniently referred to as a hydrate, for example, a mono-hydrate, a di-hydrate, a tri-hydrate, etc.

B

If R^C is $-\text{CH}_2-\text{O}-\text{C}(=\text{O})\text{R}^{C2}$ or $-\text{CH}_2-\text{O}-\text{Si}(\text{R}^{\text{Si}1})(\text{R}^{\text{Si}2})(\text{R}^{\text{Si}3})$ then the conversion of **III** to **IV** is by reduction of the nitro group. If R^C is $-\text{CH}_2-\text{O}-\text{C}(=\text{O})\text{R}^{C2}$, this reduction is carried out by using zinc in acetic acid. Alternatives include Cd/Pb couple, sodium dithionite or tin II chloride. - 10 If R^C is $-\text{C}(=\text{O})-\text{OR}^{C1}$, then the conversion of **III** to **IV** is achieved by first reducing of the ester and reprotection as an acetate or silyl ether. The reduction can be achieved by standard means, for example with LiBH_4 , or LiEt_3BH_4 . Reprotection as an acetate can be achieved, for example, by reaction with acetyl chloride; reprotection as a benzoate can be achieved, for example, by reaction with benzoyl chloride; reprotection as a silyl ether can be achieved, for example, by reaction with the appropriate silyl chloride in DMF in the presence of imidazole.

Example 1

The synthesis of the starting material is described in JP 2008050321A.

5 (a) *Compound 1*

Neat triisopropylsilylchloride (86 mL) was added to a mixture of imidazole (54.7 g) and phenol (4 g) (ground together). The mixture was heated until the phenol and imidazole

melted and went into solution (110°C). The reaction mixture was allowed to stir for 5 minutes and was then allowed to cool, whereupon a solid was observed to form at the bottom of the flask. The reaction mixture was loaded directly on to silica gel and the silica pad was washed with hexane. The desired product was eluted with 5 % ethyl acetate in hexane. Excess eluent was removed by rotary evaporation under reduced pressure to afford a quantitative amount of the product **1** (112.454 g, >100 %). LCMS RT 4.25 mins, m/z ES⁺ 353.85

(b) Compound 2

A solution of sodium chlorite (60.6 g) and sodium dihydrogenphosphate (53.2 g) (NaH₂PO₄) in water (800 mL) was added to a solution of compound **1** (112.4 g) in tetrahydrofuran (500 mL) at room temperature. Hydrogen peroxide (60 % w/w, 179.02 mL) was immediately added to the vigorously stirred biphasic mixture. The reaction was initiated by addition of 1M hydrochloric acid to lower the pH of the reaction mixture to between 5 and 6. The reaction mixture evolved gas (oxygen), the starting material dissolved and the temperature of the reaction mixture rose to 40°C. As the reaction proceeded the pH continued to drop and was kept between 5 and 6 by addition of solid sodium dihydrogenphosphate (1 – 2 g). After 1 hour LC/MS revealed that the reaction was complete. The reaction mixture was cooled in an ice bath and hydrochloric acid (1 M) was added to lower the pH to between 1 and 2. The reaction mixture was then extracted with ethyl acetate (1 L) and the organic phases washed with brine (2 x 100 mL) and dried over magnesium sulphate. The organic phase was filtered and excess solvent removed by rotary evaporation under reduced pressure to afford the product **2** in quantitative yield. LC/MS 3.93 mins, m/z ES⁺ 367.74

(c) Compound 3

A solution of acid **2** (58.60 g), hydroxybenzotriazole (26.59 g) and DCC (39.12 g) in dichloromethane (200 mL) was allowed to stir for 30 mins at which time a solution of C-ring (36.70 g) and triethylamine (33 mL) in dichloromethane (100 mL) was added at 0°C under argon. The coupling reaction proceeded rapidly and went to completion inside 1 hour, as monitored by LC/MS. The reaction mixture was filtered and diluted with dichloromethane (150 mL). The organic phase was washed sequentially with cold dilute hydrochloric acid (0.1 M), saturated aqueous sodium bicarbonate and brine. The organic layer was dried over magnesium sulphate, filtered and excess solvent removed by rotary evaporation under reduced pressure. The residue was subjected to column flash chromatography

(silica gel; gradient 40 % ethyl acetate in hexane to 80 % ethyl acetate in hexane). Excess solvent was removed by rotary evaporation under reduced pressure. A white solid was observed in the resulting residue which was removed by dissolving the residue up in diethyl ether. Removal of diethyl ether by rotary evaporation under reduced pressure afforded the
5 pure product **3**, (38.80 g, 42 % yield). LC/MS 4.43 mins, m/z ES⁺582.92

(d) Compound 4

TCCA (8.82 g) was added to a stirred solution of **3** (31.67 g) and TEMPO (0.85 g) in dry dichloromethane (250 mL) at 0°C. The reaction mixture was vigorously stirred for 20
10 minutes at room temperature, at which point TLC (50/50 ethyl acetate/hexane) revealed complete consumption of the starting material. The reaction mixture was filtered through celite and the filtrate washed with aqueous saturated sodium bicarbonate (100 mL), sodium thiosulphate (9 g in 300 mL), brine (100 mL) and dried over magnesium sulphate. Rotary evaporation under reduced pressure afforded product **4** in quantitative yield. LC/MS 4.52
15 mins, m/z ES⁺ 581.08

(e) Compound 5

Triflic anhydride (27.7 mL) was injected in one portion to a vigorously stirred suspension of compound **4** (31.86 g) in dry dichloromethane (900 mL) in the presence of 2,6-lutidine
20 (25.6 mL, dried over sieves) at -50°C (acetone/ dry ice bath). The reaction mixture was allowed to stir for 1.5 hours when LC-MS following a mini work-up (water/dichloromethane) revealed the reaction to be complete.
