(54) **Title:** GRADIENT-BASED PATTERN AND EVALUATION POINT SELECTION

(57) **Abstract:** Described herein is a method for a lithographic process for imaging a portion of a design layout onto a substrate using a lithographic imaging apparatus, the lithographic process having a plurality of design variables, the method comprising: calculating a gradient of each of a plurality of evaluation points or patterns of the lithographic process, with respect to at least one of the design variables; and selecting a subset of evaluation points from the plurality of evaluation points or patterns based on the gradient.

Gradient-Based Pattern and Evaluation Point Selection

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of US provisional application 61/653,790, which
5 was filed on May 31, 2012 and which is incorporated herein in its entirety by reference.

FIELD OF THE INVENTION

[0002] The description relates to lithographic apparatuses and processes, and more
particularly to tools for simultaneously or alternatively optimizing illumination sources, masks/
10 design layouts and projection optics for use in lithographic apparatuses and processes.

BACKGROUND

[0003] A lithographic projection apparatus can be used, for example, in the manufacture of
integrated circuits (ICs). In such a case, a mask may contain a circuit pattern corresponding to an
15 individual layer of the IC ("design layout"), and this circuit pattern can be transferred onto a
target portion (e.g. comprising one or more dies) on a substrate (e.g., silicon wafer) that has been
coated with a layer of radiation-sensitive material ("resist"), by methods such as irradiating the
target portion through the circuit pattern on the mask. In general, a single substrate contains a
plurality of adjacent target portions to which the circuit pattern is transferred successively by the
20 lithographic projection apparatus, one target portion at a time. In one type of lithographic
projection apparatuses, the circuit pattern on the entire mask is transferred onto one target
portion in one go; such an apparatus is commonly referred to as a wafer stepper. In an alternative
apparatus, commonly referred to as a step-and-scan apparatus, a projection beam scans over the
mask in a given reference direction (the "scanning" direction) while synchronously moving the
25 substrate parallel or anti-parallel to this reference direction. Different portions of the circuit
pattern on the mask are transferred to one target portion progressively. Since, in general, the
lithographic projection apparatus will have a magnification factor M (generally < 1), the speed F
at which the substrate is moved will be a factor M times that at which the projection beam scans
the mask. More information with regard to lithographic devices as described herein can be
30 gleaned, for example, from US 6,046,792, incorporated herein by reference.

[0004] Prior to transferring the circuit pattern from the mask to the substrate, the substrate may undergo various procedures, such as priming, resist coating and a soft bake. After exposure, the substrate may be subjected to other procedures, such as a post-exposure bake (PEB), development, a hard bake and measurement/inspection of the transferred circuit pattern. This array of procedures is used as a basis to make an individual layer of a device, e.g., an IC. The substrate may then undergo various processes such as etching, ion-implantation (doping), metallization, oxidation, chemo-mechanical polishing, etc., all intended to finish off the individual layer of the device. If several layers are required in the device, then the whole procedure, or a variant thereof, will have to be repeated for each layer. Eventually, a device will be present in each target portion on the substrate. These devices are then separated from one another by a technique such as dicing or sawing, whence the individual devices can be mounted on a carrier, connected to pins, etc.

[0005] As noted, microlithography is a central step in the manufacturing of ICs, where patterns formed on substrates define functional elements of the ICs, such as microprocessors, memory chips etc. Similar lithographic techniques are also used in the formation of flat panel displays, micro-electro mechanical systems (MEMS) and other devices.

[0006] As semiconductor manufacturing processes continue to advance, the dimensions of functional elements have continually been reduced while the amount of functional elements, such as transistors, per device has been steadily increasing over decades, following a trend commonly referred to as “Moore’s law”. At the current state of technology, layers of devices are manufactured using lithographic projection apparatuses that project a design layout onto a substrate using illumination from a deep-ultraviolet illumination source, creating individual functional elements having dimensions well below 100 nm, i.e. less than half the wavelength of the light from the illumination source.

[0007] This process in which features with dimensions smaller than the classical resolution limit of a lithographic projection apparatus are printed, is commonly known as low- k_1 lithography, according to the resolution formula $CD = k_1 \times \lambda / NA$, where λ is the wavelength of radiation employed (currently in most cases 248nm or 193nm), NA is the numerical aperture of projection optics in the lithographic projection apparatus, CD is the “critical dimension”—generally the smallest feature size printed—and k_1 is an empirical resolution factor. In general, the smaller k_1 the more difficult it becomes to reproduce a pattern on the wafer that resembles the

shape and dimensions planned by a circuit designer in order to achieve particular electrical functionality and performance. To overcome these difficulties, sophisticated fine-tuning steps are applied to the lithographic projection apparatus as well as to the design layout. These include, for example, but not limited to, optimization of NA and optical coherence settings, customized
5 illumination schemes, use of phase shifting masks, optical proximity correction (OPC, sometimes also referred to as “optical and process correction”) in the design layout, or other methods generally defined as “resolution enhancement techniques” (RET).

[0008] As one example, OPC addresses the fact that the final size and placement of an image of the design layout projected on the substrate will not be identical to, or simply depend
10 only on the size and placement of the design layout on the mask. It is noted that the terms “mask” and “reticle” are utilized interchangeably herein. Also, person skilled in the art will recognize that, especially in the context of lithography simulation/optimization, the term “mask” and “design layout” can be used interchangeably, as in lithography simulation/optimization, a physical mask is not necessarily used but a design layout can be used to represent a physical
15 mask. For the small feature sizes and high feature densities present on some design layout, the position of a particular edge of a given feature will be influenced to a certain extent by the presence or absence of other adjacent features. These proximity effects arise from minute amounts of light coupled from one feature to another and/or non-geometrical optical effects such as diffraction and interference. Similarly, proximity effects may arise from diffusion and other
20 chemical effects during post-exposure bake (PEB), resist development, and etching that generally follow lithography.

[0009] In order for the projected image of the design layout to be in accordance with requirements of a given target circuit design, proximity effects are predicted and compensated for, using sophisticated numerical models, corrections or pre-distortions of the design layout.
25 The article “Full-Chip Lithography Simulation and Design Analysis - How OPC Is Changing IC Design”, C. Spence, Proc. SPIE, Vol. 5751, pp 1-14 (2005) provides an overview of current “model-based” optical proximity correction processes. In a typical high-end design, most features of the design layout typically require some modification in order to achieve high fidelity of the projected image to the target design. These modifications may include shifting or biasing
30 of edge positions or line widths as well as application of “assist” features that are intended to assist projection of other features.

[0010] Application of model-based OPC to a target design requires good process models and considerable computational resources, given the many millions of features typically present in a chip design. However, applying OPC is generally not an “exact science”, but an empirical, iterative process that does not always compensate for all possible proximity effect. Therefore, effect of OPC, e.g., design layouts after application of OPC and any other RET, need to be verified by design inspection, i.e. intensive full-chip simulation using calibrated numerical process models, in order to minimize the possibility of design flaws being built into the manufacturing of a mask. This is driven by the enormous cost of making high-end masks, which run in the multi-million dollar range, as well as by the impact on turn-around time by reworking or repairing actual masks once they have been manufactured.

[0011] Both OPC and full-chip RET verification may be based on numerical modeling systems and methods as described, for example in, U.S. Patent App. No. 10/815 ,573 and an article titled “Optimized Hardware and Software For Fast, Full Chip Simulation”, by Y. Cao et al., Proc. SPIE, Vol. 5754, 405 (2005).

[0012] In addition to optimization to design layouts or masks (e.g., OPC), the illumination source can also optimized, either jointly with mask optimization or separately, in an effort to improve the overall lithography fidelity. Since the 1990s, many off-axis illumination sources, such as annular, quadrupole, and dipole, have been introduced, and have provided more freedom for OPC design, thereby improving the imaging results, As is known, off-axis illumination is a proven way to resolve fine structures (i.e., target features) contained in the mask. However, when compared to a traditional illumination source, an off-axis illumination source usually provides less light intensity for the aerial image (AI). Thus, it becomes desirable to attempt to optimize the illumination source to achieve the optimal balance between finer resolution and reduced light intensity. The terms “illumination source” and “source” are used interchangeably in this document.

[0013] Numerous illumination source optimization approaches can be found, for example, in an article by Rosenbluth et al., titled “Optimum Mask and Source Patterns to Print a Given Shape”, Journal of Microlithography, Microfabrication, Microsystems 1(1), pp.13-20, (2002). The source is partitioned into several regions, each of which corresponds to a certain region of the pupil spectrum. Then, the source distribution is assumed to be uniform in each source region and the brightness of each region is optimized for process window. However, such an

assumption that the source distribution is uniform in each source region is not always valid, and as a result the effectiveness of this approach suffers. In another example set forth in an article by Granik, titled “Source Optimization for Image Fidelity and Throughput”, Journal of Microlithography, Microfabrication, Microsystems 3(4), pp.509-522, (2004), several existing source optimization approaches are overviewed and a method based on illuminator pixels is proposed that converts the source optimization problem into a series of non-negative least square optimizations. Though these methods have demonstrated some successes, they typically require multiple complicated iterations to converge. In addition, it may be difficult to determine the appropriate/optimal values for some extra parameters, such as γ in Granik’s method, which dictates the trade-off between optimizing the source for wafer image fidelity and the smoothness requirement of the source.

[0014] For low k_1 photolithography, optimization of both the source and mask is very useful to ensure a viable process window for projection of critical circuit patterns. Some algorithms (e.g. Socha et. al. Proc. SPIE vol. 5853, 2005, p.180) discretize illumination into independent source points and mask into diffraction orders in the spatial frequency domain, and separately formulate a cost function (which is defined as a function of selected design variables) based on process window metrics such as exposure latitude which could be predicted by optical imaging models from source point intensities and mask diffraction orders. The term “design variables” as used herein means a set of parameters of a lithographic projection apparatus, for example, parameters a user of the lithographic projection apparatus can adjust. It should be appreciated that any characteristics of a lithographic projection apparatus, including those of the source, the mask, the projection optics, can be among the design variables in the optimization. The cost function is often a non-linear function of the design variables. Then standard optimization techniques are used to minimize the cost function.

[0015] These algorithms that formulate a cost function typically require a large number of full forward optical imaging model simulations before convergence on both optimal source and mask is reached. Optimizing the lithographic projection apparatus using a clip (which is defined as a portion of a design layout with calibration features that can be used for optimization of the lithographic projection apparatus, as elaborated further in the detailed description section) of medium complexity can take weeks or even months on latest standard PC hardware, which is generally considered impractical.

[0016] Relatedly, the delay of EUV lithography and the pressure of ever decreasing design rules have driven semiconductor chipmakers to move deeper into the low k_1 lithography era with existing 193 nm ArF lithography. Lithography towards lower k_1 puts heavy demands on RET, exposure tools, and the need for litho-friendly design. The 1.35 ArF hyper numerical apertures (NA) exposure tool will be the exposure tool for chip manufactures to use in the next two years. To ensure that circuit design can be produced on to the substrate with workable process window; source-mask optimization (SMO) is becoming an important RET that is used for 2x nm node.

[0017] A source and mask (design layout) optimization method and system that allow for simultaneous optimization of the source and mask using a cost function without constraints and within a practicable amount of time is described in a commonly assigned International Patent Application No. PCT/US2009/065359, filed on November 20, 2009, and published as WO2010/059954, titled "Fast Freeform Source and Mask Co-Optimization Method", which is hereby incorporated by reference in its entirety.

[0018] New development in hardware and software of lithographic projection apparatuses provides more flexibility by making projection optics therein adjustable. The term "projection optics" as used herein should be broadly interpreted as encompassing various types of optical systems, including refractive optics, reflective optics, apertures and catadioptric optics, for example. The term "projection optics" may also include components operating according to any of these design types for directing, shaping or controlling the projection beam of radiation, collectively or singularly. The term "projection optics" may include any optical component in the lithographic projection apparatus, no matter where the optical component is located on an optical path of the lithographic projection apparatus. Projection optics can include optical components for shaping, adjusting and/or projecting light from the source before the light passes the mask, and/or optical components for shaping, adjusting and/or projecting the light after the light passes the mask. The projection optics generally exclude the source and the mask.

[0019] For example, adjustable parameters ("knobs") of the projection optics make it possible to shape light in more degrees of freedom (e.g., wavefront shape, intensity distribution, etc.) and/or to accommodate a wider range of conditions of the source and the mask (namely to provide a larger process window (PW)), than what is offered by the existing SMO techniques.

[0020] However, optimizing these additional knobs entails very high computation cost. Therefore, methods to simplify and accelerate optimization of these knobs related to the projection optics jointly with knobs associated with the source and mask is desirable.

[0021] Therefore what is needed is a computationally-efficient comprehensive optimization method for characterizing a lithographic process based on which the setting of a lithographic apparatus (including setting of a projection optics system) is decided and a mask is designed.

SUMMARY

[0022] Described herein is a method for a lithographic process for imaging a portion of a design layout onto a substrate using a lithographic imaging apparatus, the lithographic process having a plurality of design variables, the method comprising: calculating a gradient of each of a plurality of evaluation points or patterns of the lithographic process, with respect to at least one of the design variables; and selecting a subset of evaluation points from the plurality of evaluation points or patterns based on the gradient.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION

[0035] Embodiments as described herein provide methods for improving or optimizing a lithographic projection apparatus including improving or optimizing projection optics therein, and preferably including the capability of improving or optimizing a source, a mask, and the projection optics, simultaneously or alternatively. The projection optics is sometimes referred to as “lens”, and therefore the joint optimization process may be termed source mask lens optimization (SMLO). Another term used to describe the SMLO process is source mask pupil optimization (SMPO), as in certain embodiments, lens optimization is done for the pupil plane of the projection optics. However, the scope is not restricted to optimization in the pupil plane only. SMLO is desirable over existing source mask optimization process (SMO), partially because including the projection optics in the optimization can lead to a larger process window by introducing a plurality of adjustable characteristics of the projection optics. The projection optics can be used to shape a wavefront in the lithographic projection apparatus. According to an embodiment herein, the optimization can be accelerated. Although adjustable characteristics of the projection optics, the source and the mask are used in the description of an embodiment, other adjustable characteristics of the lithographic projection apparatus, such as, dose and focus, can be adjusted in the optimization.

25 [0036] An embodiment herein improve or optimize the lithographic projection apparatus by minimizing a suitable cost function of design variables that can be characteristics of the source, projection optics, and the mask. Non-limiting examples of the cost function are given. Other forms of the cost function are also possible and can accommodate a wide variety of lithography metrics. The cost function can be a linear or non-linear function of the design variables.

[0037] Methods of simultaneous SMLO and alternative SMLO have been disclosed. The SMLO process can be accelerated by combining the SMLO with a various pattern selection methods.

[0038] Although specific reference may be made in this text to the manufacture of ICs, it should be explicitly understood that many other applications are possible. For example, the manufacture of integrated optical systems, guidance and detection patterns for magnetic domain memories, liquid-crystal display panels, thin-film magnetic heads, etc. The skilled artisan will appreciate that, in the context of such alternative applications, any use of the terms "reticle", "wafer" or "die" in this text should be considered as interchangeable with the more general terms "mask", "substrate" and "target portion", respectively.

[0039] In the present document, the terms "radiation" and "beam" are used to encompass all types of electromagnetic radiation, including ultraviolet radiation (e.g. with a wavelength of 365, 248, 193, 157 or 126 nm) and EUV (extreme ultra-violet radiation, e.g. having a wavelength in the range 5-20 nm).

[0040] The term "optimizing" and "optimization" as used herein mean adjusting a lithographic projection apparatus such that results and/or processes of lithography have more desirable characteristics, such as higher accuracy of projection of design layouts on a substrate, larger process windows, etc.

[0041] Further, the lithographic projection apparatus may be of a type having two or more substrate tables (and/or two or more mask tables). In such "multiple stage" devices the additional tables may be used in parallel, or preparatory steps may be carried out on one or more tables while one or more other tables are being used for exposures. Twin stage lithographic projection apparatuses are described, for example, in US 5,969,441, incorporated herein by reference.

[0042] The mask referred to above comprise design layouts. The design layouts can be generated utilizing CAD (computer-aided design) programs, this process often being referred to as EDA (electronic design automation). Most CAD programs follow a set of predetermined design rules in order to create functional design layouts/masks. These rules are set by processing and design limitations. For example, design rules define the space tolerance between circuit devices (such as gates, capacitors, etc.) or interconnect lines, so as to ensure that the circuit devices or lines do not interact with one another in an undesirable way. The design rule limitations are typically referred to as "critical dimensions" (CD). A critical dimension of a

circuit can be defined as the smallest width of a line or hole or the smallest space between two lines or two holes. Thus, the CD determines the overall size and density of the designed circuit. Of course, one of the goals in integrated circuit fabrication is to faithfully reproduce the original circuit design on the substrate (via the mask).

5 [0043] The term mask as employed in this text may be broadly interpreted as referring to generic patterning means that can be used to endow an incoming radiation beam with a patterned cross-section, corresponding to a pattern that is to be created in a target portion of the substrate; the term “light valve” can also be used in this context. Besides the classic mask (transmissive or reflective; binary, phase-shifting, hybrid, etc.), examples of other such patterning means include:

10 -a programmable mirror array. An example of such a device is a matrix-addressable surface having a viscoelastic control layer and a reflective surface. The basic principle behind such an apparatus is that (for example) addressed areas of the reflective surface reflect incident light as diffracted light, whereas unaddressed areas reflect incident light as undiffracted light. Using an appropriate filter, the said undiffracted light can be filtered out of the reflected beam, leaving
15 only the diffracted light behind; in this manner, the beam becomes patterned according to the addressing pattern of the matrix-addressable surface. The required matrix addressing can be performed using suitable electronic means. More information on such mirror arrays can be gleaned, for example, from U. S. Patent Nos. 5,296,891 and 5,523,193, which are incorporated herein by reference.

20 -a programmable LCD array. An example of such a construction is given in U. S. Patent No. 5,229,872, which is incorporated herein by reference.

[0044] As a brief introduction, Fig. 1 illustrates an exemplary lithographic projection apparatus 10. Major components are an illumination source 12, which may be a deep-ultraviolet excimer laser source or other type of sources including extreme ultra violet (EUV) sources,
25 illumination optics which define the partial coherence (denoted as sigma) and which may include optics 14, 16a and 16b that shape light from the source 12; a mask or reticle 18; and transmission optics 16c that project an image of the reticle pattern onto a substrate plane 22. An adjustable filter or aperture 20 at the pupil plane of the projection optics may restrict the range of beam angles that impinge on the substrate plane 22, where the largest possible angle defines the
30 numerical aperture of the projection optics $NA = \sin(\Theta_{\max})$.

[0045] In an optimization process of a system, a figure of merit of the system can be represented as a cost function. The optimization process boils down to a process of finding a set of parameters (design variables) of the system that minimizes the cost function. The cost function can have any suitable form depending on the goal of the optimization. For example, the cost function can be weighted root mean square (RMS) of deviations of certain characteristics (evaluation points) of the system with respect to the intended values (e.g., ideal values) of these characteristics; the cost function can also be the maximum of these deviations. The term “evaluation points” herein should be interpreted broadly to include any characteristics of the system. The design variables of the system can be confined to finite ranges and/or be interdependent due to practicalities of implementations of the system. In case of a lithographic projection apparatus, the constraints are often associated with physical properties and characteristics of the hardware such as tunable ranges, and/or mask manufacturability design rules, and the evaluation points can include physical points on a resist image on a substrate or points on patterns in a design layout as usually interpreted in the lithography industry, as well as non-physical characteristics such as dose and focus as broadly defined herein. For example, these physical points can be points inside, outside, or on the edge of patterns on a resist image or in a design layout.

[0046] In a lithographic projection apparatus, a source provides illumination (i.e. light); projection optics direct and shapes the illumination through a mask and onto a substrate. The term “projection optics” is broadly defined here to include any optical component that may alter the wavefront of the radiation beam. For example, projection optics may include at least some of the components 14, 16a, 16b and 16c. An aerial image (AI) is the light intensity distribution on the substrate. A resist layer on the substrate is exposed and the aerial image is transferred to the resist layer as a latent “resist image” (RI) therein. The resist image (RI) can be defined as a spatial distribution of solubility of the resist in the resist layer. A resist model can be used to calculate the resist image from the aerial image, an example of which can be found in commonly assigned U.S. Patent Application Serial No. 12/315,849, disclosure of which is hereby incorporated by reference in its entirety. The resist model is related only to properties of the resist layer (e.g., effects of chemical processes which occur during exposure, PEB and development). Optical properties of the lithographic projection apparatus (e.g., properties of the source, the mask and the projection optics) dictate the aerial image. Since the mask used in the

lithographic projection apparatus can be changed, it is desirable to separate the optical properties of the mask from the optical properties of the rest of the lithographic projection apparatus including at least the source and the projection optics.

[0047] An exemplary flow chart for simulating lithography in a lithographic projection apparatus is illustrated in Fig. 2. A source model 31 represents optical characteristics (including light intensity distribution and/or phase distribution) of the source. A projection optics model 32 represents optical characteristics (including changes to the light intensity distribution and/or the phase distribution caused by the projection optics) of the projection optics. The source model 31 and the projection optics model 32 can be combined, as explained later herein, into a transmission cross coefficient (TCC) model 34. A design layout model 35 represents optical characteristics (including changes to the light intensity distribution and/or the phase distribution caused by a given design layout 33) of a design layout 33, which is the representation of an arrangement of features on a mask. An aerial image 36 can be simulated from the transmission cross coefficient 34 and the design layout model 35. A resist image 37 can be simulated from the aerial image 36 using a resist model 37. Simulation of lithography can, for example, predict contours and CDs in the resist image.

[0048] More specifically, it is noted that the source model 31 can represent the optical characteristics of the source that include, but not limited to, NA-sigma (σ) settings as well as any particular illumination source shape (e.g. off-axis light sources such as annular, quadrupole, and dipole, etc.). The projection optics model 32 can represent the optical characteristics of the of the projection optics that include aberration, distortion, refractive indexes, physical sizes, physical dimensions, etc. The design layout model 35 can also represent physical properties of a physical mask, as described, for example, in U.S. Patent No. 7,587,704, which is incorporated by reference in its entirety. The objective of the simulation is to accurately predict, for example, edge placements and CDs, which can then be compared against an intended design. The intended design is generally defined as a pre-OPC design layout which can be provided in a standardized digital file format such as GDSII or OASIS or other file format.

[0049] From this design layout, one or more portions may be identified, which are referred to as "clips". In a specific embodiment, a set of clips is extracted, which represents the complicated patterns in the design layout (typically about 50 to 1000 clips, although any number of clips may be used). As will be appreciated by those skilled in the art, these patterns or clips represent small

portions (i.e. circuits, cells or patterns) of the design and especially the clips represent small portions for which particular attention and/or verification is needed. In other words, clips may be the portions of the design layout or may be similar or have a similar behavior of portions of the design layout where critical features are identified either by experience (including clips provided
 5 by a customer), by trial and error, or by running a full-chip simulation. Clips usually contain one or more test patterns or gauge patterns.

[0050] An initial larger set of clips may be provided a priori by a customer based on known critical feature areas in a design layout which require particular image optimization.

Alternatively, in another embodiment, the initial larger set of clips may be extracted from the
 10 entire design layout by using some kind of automated (such as, machine vision) or manual algorithm that identifies the critical feature areas.

[0051] To reduce the overall computation burden, various ways of optimization can be envisioned. In one embodiment, first a set of clips is selected by a pattern selection method based on diffraction signature analysis or any other method, and then the SMLO process is
 15 performed. Alternatively, first a full chip simulation is performed, ‘hot spots’ and/or ‘warm spots’ are identified from the full chip simulation, and then a pattern selection step is performed. The optimization is done based on the selected patterns. The pattern selection algorithm (based on diffraction signature analysis or other methods) can be seamlessly integrated with the SMLO process. These example methods are described further with respect to Figures 4B-4D.

[0052] In a lithographic projection apparatus, as an example, a cost function is expressed as
 20

$$CF(z_1, z_2, \dots, z_N) = \sum_{p=1}^P w_p f_p^2(z_1, z_2, \dots, z_N) \quad (\text{Eq. 1})$$

wherein $(z_1, z_2, \dots, z_N)$ are N design variables or values thereof; $f_p(z_1, z_2, \dots, z_N)$ is a difference between an actual value and an intended value of the p -th evaluation point (or interchangeably “cost term”) for a set of values of the design variables of $(z_1, z_2, \dots, z_N)$.

w_p is a weight constant assigned to the p -th evaluation point. An evaluation point or pattern
 25 more critical than others can be assigned a higher w_p value. Patterns and/or evaluation points with larger number of occurrences may be assigned a higher w_p value, too. Examples of the evaluation points can be any physical point or pattern on the wafer, or any point on a virtual

design layout, or resist image, or aerial image. The cost function may represent any suitable characteristics of the lithographic projection apparatus or the substrate, for instance, focus, CD, image shift, image distortion, image rotation, etc. Since it is the resist image that often dictates the circuit pattern on a substrate, the cost function often includes functions that represent some characteristics of the resist image. For example, $f_p(z_1, z_2, \dots, z_N)$ can be simply a distance between a point in the resist image to an intended position of that point (i.e., edge placement error $EPE_p(z_1, z_2, \dots, z_N)$). The design variables can be any adjustable parameters such as adjustable parameters of the source, the mask, the projection optics, dose, focus, etc. Preferably, at least some of the design variables are adjustable characteristics of the projection optics. The projection optics may include components collectively called as “wavefront manipulator” that can be used to adjust shapes of a wavefront and intensity distribution and/or phase shift of the irradiation beam. The projection optics preferably can adjust a wavefront and intensity distribution at any location along an optical path of the lithographic projection apparatus, such as before the mask, near a pupil plane, near an image plane, near a focal plane. The projection optics can be used to correct or compensate for certain distortions of the wavefront and intensity distribution caused by, for example, the source, the mask, temperature variation in the lithographic projection apparatus, thermal expansion of components of the lithographic projection apparatus. Adjusting the wavefront and intensity distribution can change values of the evaluation points and the cost function. Such changes can be simulated from a model or actually measured.

[0053] It should be noted that the normal weighted root mean square (RMS) of

$f_p(z_1, z_2, \dots, z_N)$ is defined as $\sqrt{\frac{1}{P} \sum_{p=1}^P w_p f_p^2(z_1, z_2, \dots, z_N)}$, therefore, minimizing

the weighted RMS of $f_p(z_1, z_2, \dots, z_N)$ is equivalent to minimizing the cost function

$CF(z_1, z_2, \dots, z_N) = \sum_{p=1}^P w_p f_p^2(z_1, z_2, \dots, z_N)$, defined in Eq. 1. Thus the weighted RMS of

$f_p(z_1, z_2, \dots, z_N)$ and Eq. 1 may be utilized interchangeably for notational simplicity herein.

[0054] Further, if we are considering maximizing the PW (Process Window), we can consider the same physical location from different PW conditions as different evaluation points in the cost function in (Eq.1). For example, if we are considering N PW conditions, then we can categorize the evaluation points according to their PW conditions and write the cost functions as:

$$5 \quad CF(z_1, z_2, \dots, z_N) = \sum_{p=1}^P w_p f_p^2(z_1, z_2, \dots, z_N) = \sum_{u=1}^U \sum_{p_u=1}^{P_u} w_{p_u} f_{p_u}^2(z_1, z_2, \dots, z_N) \quad (\text{Eq. 1'})$$

Where $f_{p_u}(z_1, z_2, \dots, z_N)$ is the difference between an actual value and an intended value of the p_i -th evaluation point for a set of values of the design variables of $(z_1, z_2, \dots, z_N)$ under the u -th PW condition $u = 1, \dots, U$. When this difference is the EPE, then minimizing the above cost function is equivalent to minimizing the edge shift under various PW conditions, thus this leads to maximizing the PW. In particular, if the PW also consists of different mask bias, then minimizing the above cost function also includes the minimization of MEEF (Mask Error Enhancement Factor), which is defined as the ratio between the wafer EPE and the induced mask edge bias.

[0055] The design variables may have constraints, which can be expressed as
 15 $(z_1, z_2, \dots, z_N) \in Z$, where Z is a set of possible values of the design variables.

[0056] The optimization process therefore is to find a set of values of the design variables, under the constraints $(z_1, z_2, \dots, z_N) \in Z$, that minimize the cost function, i.e., to find

$$\begin{aligned} (\tilde{z}_1, \tilde{z}_2, \dots, \tilde{z}_N) &= \arg \min_{(z_1, z_2, \dots, z_N) \in Z} CF(z_1, z_2, \dots, z_N) = \\ &\arg \min_{(z_1, z_2, \dots, z_N) \in Z} \sum_{p=1}^P w_p f_p^2(z_1, z_2, \dots, z_N) \end{aligned} \quad (\text{Eq. 2})$$

[0057] A general method of optimizing the lithography projection apparatus, according to an embodiment, is illustrated in Fig. 3. This method comprises a step 302 of defining a multi-variable cost function of a plurality of design variables. At least some of the design variables being characteristics of the projection optics, as shown in step 300B. Other design variables may be associated with illumination source (step 300A) and the design layout (step 300C). In step 304, the design variables are simultaneously adjusted so that the cost function is moved towards
 25 convergence. In step 306, it is determined whether a predefined termination condition is satisfied.

The predetermined termination condition may include various possibilities, i.e. the cost function may be minimized or maximized, as required by the numerical technique used, the value of the cost function has been equal to a threshold value or has crossed the threshold value, the value of the cost function has reached within a preset error limit, or a preset number of iteration is reached.

5 If either of the conditions in step 306 is satisfied, the method ends. If none of the conditions in step 306 is satisfied, the step 304 and 306 are iteratively repeated until a desired result is obtained.

[0058] In a lithographic projection apparatus, the source, mask and projection optics can be optimized alternatively (referred to as Alternative Optimization) or optimized simultaneously (referred to as Simultaneous Optimization), according to embodiments. The terms
10 “simultaneous”, “simultaneously”, “joint” and “jointly” as used herein mean that the design variables of the characteristics of the source, mask, projection optics and/or any other design variables, are allowed to change at the same time. The term “alternative” and “alternatively” as used herein mean that not all of the design variables are allowed to change at the same time.

15 **[0059]** In Fig. 3, the optimization of all the design variables is executed simultaneously. We call such flow the simultaneous flow or co-optimization flow. Alternatively, the optimization of all the design variables is executed alternatively, as illustrated in Fig. 4A. In this flow, in each step, some design variables are fixed while the other design variables are optimized to minimize the cost function; then in the next step, a different set of variables are fixed while the others are
20 optimized to minimize the cost function. These steps are executed alternatively until convergence or certain terminating conditions are met. As shown in the non-limiting example flowchart of Fig. 4A, we first obtain a design layout (step 402), then execute a step of SMO (Source-Mask-Optimization) in step 404, where all the design variables from projection optics are fixed while all the other design variables (from the illumination source and mask design
25 layout) are optimized to minimize the cost function. Then in the next step 406, an LO (Lens Optimization) is performed, where all the design variables from the illumination source and mask design layout are fixed, while the design variables from projection optics optimized to minimize the cost function. These two steps are executed alternatively, until certain terminating conditions are met in step 408. Various termination conditions can be used, such as, the value of
30 the cost function becomes equal to a threshold value, the value of the cost function crosses the threshold value, the value of the cost function reaches within a preset error limit, or a preset

number of iteration is reached, etc. Note that we use SMO-LO-Alternative-Optimization as an example for the alternative flow. The alternative flow can take many different forms, such as SO-LO-MO-Alternative-Optimization, where we execute SO (Source Optimization), LO (Lens Optimization), and MO (Mask Optimization) alternatively and iteratively; or we can first execute SMO once, then execute LO and MO alternatively and iteratively; and so on. Finally the output of the optimization result is obtained in step 410, and the process stops.

[0060] Persons skilled in the art will also appreciate that pattern selection algorithm, as discussed before, may be integrated with the simultaneous or alternative SMLO. For example, when an alternative SMLO is adopted, first a full-chip SMO can be performed, the 'hot spots' and/or 'warm spots' are identified, then an LO or SLO (source-lens optimization) is performed. Persons skilled in the art will appreciate in view of the present disclosure that numerous permutations and combinations of sub-optimizations are possible in order to achieve the desired optimization results.

[0061] In one example embodiment shown in the flowchart in Fig. 4B, pattern selection is integrated into SMLO to further speed up the optimization process, which is especially useful for full-chip (or whole design layout) optimization. If there are too many clips with too many test patterns (also known as "gauges" or "gauge patterns") and/or too many evaluation points, the optimization may be too slow or require too much storage. Thus, in one embodiment, in order to reduce the computational cost for large design layout with many gauge patterns, we apply pattern selection to all the gauge patterns. For example, in step 420 we can first identify some important clips (e.g., based on the diffraction characteristics), then in step 422, we can do SMLO for all the evaluation points in these clips, and then, in step 424, we can fix the illumination and projection optics functions from SMLO results, and perform Mask Optimization for the entire design layout. The process terminates in step 426 when the termination conditions are satisfied.

[0062] Alternatively, we can identify the gauges through hot spots or warm spots, i.e., the defects or patterns which are almost defects. Such an alternative flow is shown in Fig. 4C. In particular, we can first run a full-chip SMO (step 430) or MO only fixing at least the projection optics characteristics, and identify the hot and warm spots in step 432. If the process window is not good enough, as determined in step 434, the hot spots and warm spots are converted to gauges in step 436. In step 438, a gauge selection or pattern selection method is performed to reduce the number of gauges and add the selected gauges into a gauge pool. In step 440, SMLO

is executed on the selected gauge pool. This process can be repeated if necessary. Note that these two alternative flows of Figs. 4A and 4B can also be applied in combination with other modifications. For example, we can first apply the first flow of Fig. 4A, then identify the resulting hot and warm spots, then apply the second flow of Fig. 4B.

5 [0063] One example SMLO method according to an embodiment will be explained in connection with the flowchart in Fig. 4D. A similar method can be found in commonly assigned U.S. Patent Application Serial No. 12/914,946, filed October 28, 2010, the disclosure of which is hereby incorporated by reference in its entirety. The difference between the '946 application and the present application is that the '946 application emphasizes on SMO, while the present
10 application emphasizes on SMLO.

[0064] In Fig. 4D, a target design layout 4300 (typically comprising a layout in a standard digital format such as OASIS, GDSII, etc.) for which a lithographic process is to be optimized includes memory, test patterns and logic. From this design layout, a full set of clips 4302 is extracted, which represents all the complicated patterns in the design 4300 (typically about 50 to
15 1000 clips). As will be appreciated by those skilled in the art, these clips represent small portions (i.e. circuits, cells or patterns) of the design for which particular attention and/or verification is needed.

[0065] As generally shown in 4304, a small subset of clips 4306 (e.g. 15 to 50 clips) is selected from the full set 4302. As will be explained in more detail below, the selection of clips
20 is preferably performed such that the process window of the selected patterns as closely as possible matches the process window for the full set of critical patterns. The effectiveness of the selection is also measured by the total turn run time (pattern selection and SMLO) reduction.

[0066] In 4308, SMLO is performed with the selected patterns (15 to 50 patterns) 4306. More particularly, an illumination source is optimized for the selected patterns 4306. This
25 optimization can be performed using any of a wide variety of known methods, for example those described in U.S. Patent Pub. No. 2004/0265707, the contents of which are incorporated herein by reference.

[0067] In 4310, manufacturability verification of the selected patterns 4306 is performed with the source and projection optics obtained in 4308. More particularly, verification includes
30 performing an aerial image simulation of the selected patterns 4306 and the optimized source and projection optics and verifying that the patterns will print across a sufficiently wide process

window. This verification can be performed using any of a wide variety of known methods, for example those described in U.S. Patent No. 7,342,646, the contents of which are incorporated herein by reference.

[0068] If the verification in 4310 is satisfactory, as determined in 4312, then processing advances to full chip optimization in 4314. Otherwise, processing returns to 4308, where SMLO is performed again but with a different source or set of patterns. For example, the process performance as estimated by the verification tool can be compared against thresholds for certain process window parameters such as exposure latitude and depth of focus. These thresholds can be predetermined or set by a user.

[0069] In 4316, after the selected patterns meet lithography performance specifications as determined in 4312, the optimized source and projection optics 4314 will be used for optimization of the full set of clips.

[0070] In 4318, model-based sub-resolution assist feature placement (MB-SRAF) and optical proximity correction (OPC) for all the patterns in the full set of clips 4316 is performed. This process can be performed using any of a wide variety of known methods, for example those described in U.S. Patent Nos. 5,663,893, 5,821,014, 6,541,167 and 6,670,081.

[0071] In 4320, using processes similar to step 4310, full pattern simulation based manufacturability verification is performed with the optimized source and projection optics 4314 and the full set of clips 4316 as corrected in 4318.

[0072] In 4322, the performance (e.g. process window parameters such as exposure latitude and depth of focus) of the full set of clips 4316 is compared against the subset of clips 4306. In one example embodiment, the pattern selection is considered complete and/or the source and projection optics are fully qualified for the full chip when the similar (< 10%) lithography performances are obtained for both selected patterns (15 to 20) 4306 and all critical patterns (50 to 1000) 4316.

[0073] Otherwise, in 4324, hotspots are extracted, and in 4326 these hotspots are added to the subset 4306, and the process starts over. For example, hotspots (i.e. features among the full set of clips 4316 that limit process window performance) identified during verification 4320 are used for further source tuning or to re-run SMLO. The source and projection optics are considered fully converged when the process window of the full set of clips 4316 are the same between the last run and the run before the last run of 4322.

[0074] Therefore, from the above non-limiting examples, the reader should appreciate that SMLO is readily accommodated within the existing optimization framework in various forms. We now revert to the mathematical background of a generic SMLO process.

[0075] As discussed before, optimization of the cost function (CF) is at the center of the

SMLO method. CF can be an RMS value of some lithographic metric. Of course,

$CF(z_1, z_2, \dots, z_N)$ is not limited to RMS of $f_p(z_1, z_2, \dots, z_N)$. $CF(z_1, z_2, \dots, z_N)$ can be in any other suitable form.

[0076] Fig. 5 shows one exemplary method of optimization, where a cost function is

minimized. In step 502, initial values of design variables are obtained, including their tuning

ranges, if any. In step S504, the multi-variable cost function is set up. In step S506, the cost function is expanded within a small enough neighborhood around the starting point value of the design variables for the first iterative step ($i=0$). In step S508, standard multi-variable

optimization techniques are applied to minimize the cost function. Note that the optimization

problem can apply constraints, such as tuning ranges, during the optimization process in S508 or

at a later stage in the optimization process. Step S520 indicates that each iteration is done for the given test patterns (also known as “gauges”) for the identified evaluation points that have been selected to optimize the lithographic process. In step S510, a lithographic response is predicted.

In step S512, the result of step S510 is compared with a desired or ideal lithographic response

value obtained in step S522. If the termination condition is satisfied in step S514, i.e. the

optimization generates a lithographic response value sufficiently close to the desired value, and

then the final value of the design variables is outputted in step S518. The output step may also

include outputting other functions using the final values of the design variables, such as

outputting an wavefront aberration-adjusted map at the pupil plane (or other planes), an

optimized source map, and optimized design layout etc. If the termination condition is not

satisfied, then in step S516, the values of the design variables is updated with the result of the i -

th iteration, and the process goes back to step S506. The entire process of Fig. 5 is elaborated in details below.

[0077] In a first exemplary optimization process, no relationship between the design

variables $(z_1, z_2, \dots, z_N)$ and $f_p(z_1, z_2, \dots, z_N)$ is assumed or approximated, except that

$f_p(z_1, z_2, \dots, z_N)$ is sufficiently smooth (e.g. first order derivatives

$\frac{\partial f_p(z_1, z_2, \dots, z_N)}{\partial z_n}, (n = 1, 2, \dots, N)$ exist), which is generally valid in a lithographic projection

apparatus. An algorithm, such as the Gauss–Newton algorithm, the Levenberg-Marquardt algorithm, the gradient descent algorithm, simulated annealing, the genetic algorithm, can be applied to find $(\tilde{z}_1, \tilde{z}_2, \dots, \tilde{z}_N)$.

5 **[0078]** Here, the Gauss–Newton algorithm is used as an example. The Gauss–Newton algorithm is an iterative method applicable to a general non-linear multi-variable optimization problem. In the i -th iteration wherein the design variables $(z_1, z_2, \dots, z_N)$ take values of

$(z_{1i}, z_{2i}, \dots, z_{Ni})$, the Gauss–Newton algorithm linearizes $f_p(z_1, z_2, \dots, z_N)$ in the vicinity of

$(z_{1i}, z_{2i}, \dots, z_{Ni})$, and then calculates values $(z_{1(i+1)}, z_{2(i+1)}, \dots, z_{N(i+1)})$ in the vicinity

10 of $(z_{1i}, z_{2i}, \dots, z_{Ni})$ that give a minimum of $CF(z_1, z_2, \dots, z_N)$. The design variables

$(z_1, z_2, \dots, z_N)$ take the values of $(z_{1(i+1)}, z_{2(i+1)}, \dots, z_{N(i+1)})$ in the $(i+1)$ -th iteration.

This iteration continues until convergence (i.e. $CF(z_1, z_2, \dots, z_N)$ does not reduce any further) or a preset number of iterations is reached.

[0079] Specifically, in the i -th iteration, in the vicinity of $(z_{1i}, z_{2i}, \dots, z_{Ni})$,

$$15 \quad f_p(z_1, z_2, \dots, z_N) \approx f_p(z_{1i}, z_{2i}, \dots, z_{Ni}) + \sum_{n=1}^N \frac{\partial f_p(z_1, z_2, \dots, z_N)}{\partial z_n} \bigg|_{z_1=z_{1i}, z_2=z_{2i}, \dots, z_N=z_{Ni}} (z_n - z_{ni}) \quad (\text{Eq. 3})$$

[0080] Under the approximation of Eq. 3, the cost function becomes:

$$CF(z_1, z_2, \dots, z_N) = \sum_{p=1}^P w_p f_p^2(z_1, z_2, \dots, z_N) \\ = \sum_{p=1}^P w_p \left(f_p(z_{1i}, z_{2i}, \dots, z_{Ni}) + \sum_{n=1}^N \frac{\partial f_p(z_1, z_2, \dots, z_N)}{\partial z_n} \bigg|_{z_1=z_{1i}, z_2=z_{2i}, \dots, z_N=z_{Ni}} (z_n - z_{ni}) \right)^2 \quad (\text{Eq. 4})$$

which is a quadratic function of the design variables $(z_1, z_2, \dots, z_N)$. Every term is constant except the design variables $(z_1, z_2, \dots, z_N)$.

[0081] If the design variables $(z_1, z_2, \dots, z_N)$ are not under any constraints,

$(z_{1(i+1)}, z_{2(i+1)}, \dots, z_{N(i+1)})$ can be derived by solving by N linear equations:

$$5 \quad \frac{\partial CF(z_1, z_2, \dots, z_N)}{\partial z_n} = 0, \text{ wherein } n=1, 2, \dots, N.$$

[0082] If the design variables $(z_1, z_2, \dots, z_N)$ are under the constraints in the form of J

inequalities (e.g. tuning ranges of $(z_1, z_2, \dots, z_N)$) $\sum_{n=1}^N A_{nj} z_n \leq B_j$, for $j=1, 2, \dots, J$; and

K equalities (e.g. interdependence between the design variables) $\sum_{n=1}^N C_{nk} z_n = D_k$,

for $k=1, 2, \dots, K$; the optimization process becomes a classic quadratic programming problem,

10 wherein A_{nj} , B_j , C_{nk} , D_k are constants. Additional constraints can be imposed for each iteration. For example, a “damping factor” Δ_D can be introduced to limit the difference between

$(z_{1(i+1)}, z_{2(i+1)}, \dots, z_{N(i+1)})$ and $(z_{1i}, z_{2i}, \dots, z_{Ni})$, so that the approximation of Eq. 3

holds. Such constraints can be expressed as $z_{ni} - \Delta_D \leq z_n \leq z_{ni} + \Delta_D$.

$(z_{1(i+1)}, z_{2(i+1)}, \dots, z_{N(i+1)})$ can be derived using, for example, methods described in

15 Numerical Optimization (2nd ed.) by Jorge Nocedal and Stephen J. Wright (Berlin New York: Vandenberghe. Cambridge University Press).

[0083] Instead of minimizing the RMS of $f_p(z_1, z_2, \dots, z_N)$, the optimization process can minimize magnitude of the largest deviation (the worst defect) among the evaluation points to their intended values. In this approach, the cost function can alternatively be expressed as

$$20 \quad CF(z_1, z_2, \dots, z_N) = \max_{1 \leq p \leq P} \frac{f_p(z_1, z_2, \dots, z_N)}{CL_p} \quad (\text{Eq. 5}),$$

wherein CL_p is the maximum allowed value for the p -th evaluation point. This cost function

represents the worst defect among the evaluation points. Optimization using this cost function minimizes magnitude of the worst defect. An iterative greedy algorithm can be used for this optimization.

[0084] The cost function of Eq. 5 can be approximated as:

$$CF(z_1, z_2, \dots, z_N) = \sum_{p=1}^P \left(\frac{f_p(z_1, z_2, \dots, z_N)}{CL_p} \right)^q \quad (\text{Eq. 6}),$$

wherein q is an even positive integer such as at least 4, preferably at least 10. Eq. 6 mimics the behavior of Eq. 5, while allowing the optimization to be executed analytically and accelerated by using methods such as the deepest descent method, the conjugate gradient method, etc.

[0085] Minimizing the worst defect size can also be combined with linearizing of

10 $f_p(z_1, z_2, \dots, z_N)$. Specifically, $f_p(z_1, z_2, \dots, z_N)$ is approximated as in Eq. 3. Then the

constraints on worst defect size are written as inequalities $E_{Lp} \leq f_p(z_1, z_2, \dots, z_N) \leq E_{Up}$,

wherein E_{Lp} and E_{Up} are two constants specifying the minimum and maximum allowed

deviation for the p-th evaluation point. Plugging Eq. 3 in, these constraints are transformed to, for $p=1, \dots, P$,

$$\begin{aligned} & \sum_{n=1}^N \frac{\partial f_p(z_1, z_2, \dots, z_N)}{\partial z_n} \bigg|_{z_1=z_{1i}, z_2=z_{2i}, \dots, z_N=z_{Ni}} \quad z_n \leq E_{Up} \\ & + \sum_{n=1}^N \frac{\partial f_p(z_1, z_2, \dots, z_N)}{\partial z_n} \bigg|_{z_1=z_{1i}, z_2=z_{2i}, \dots, z_N=z_{Ni}} \quad z_{ni} - f_p(z_{1i}, z_{2i}, \dots, z_{Ni}) \end{aligned}$$

(Eq. 6')

and

$$\begin{aligned}
& - \sum_{n=1}^N \frac{\partial f_p(z_1, z_2, \dots, z_N)}{\partial z_n} \bigg|_{z_1=z_{1i}, z_2=z_{2i}, \dots, z_N=z_{Ni}} \\
& z_n \leq -E_{Up} - \sum_{n=1}^N \frac{\partial f_p(z_1, z_2, \dots, z_N)}{\partial z_n} \bigg|_{z_1=z_{1i}, z_2=z_{2i}, \dots, z_N=z_{Ni}} \quad z_{ni} + f_p(z_{1i}, z_{2i}, \dots, z_{Ni})
\end{aligned}
\tag{Eq. 6''}$$

[0086] Since Eq. 3 is generally valid only in the vicinity of $(z_{1i}, z_{2i}, \dots, z_{Ni})$, in case the

desired constraints $E_{Lp} \leq f_p(z_1, z_2, \dots, z_N) \leq E_{Up}$ cannot be achieved in such vicinity, which can be determined by any conflict among the inequalities, the constants E_{Lp} and E_{Up} can be relaxed until the constraints are achievable. This optimization process minimizes the worst defect size in the vicinity of $(z_{1i}, z_{2i}, \dots, z_{Ni})$. Then each step reduces the worst defect size gradually, and we execute each step iteratively until certain terminating conditions are met. This will lead to optimal reduction of the worst defect size.

[0087] Another way to minimize the worst defect is to adjust the weight w_p in each iteration. For example, after the i -th iteration, if the r -th evaluation point is the worst defect, w_r can be increased in the $(i+1)$ -th iteration so that the reduction of that evaluation point's defect size is given higher priority.

[0088] In addition, we can modify the cost functions in Eq.4 and Eq.5 by introducing a Lagrange multiplier to achieve compromise between the optimization on RMS of the defect size and the optimization on the worst defect size, i.e.,

$$CF(z_1, z_2, \dots, z_N) = (1 - \lambda) \sum_{p=1}^P w_p f_p^2(z_1, z_2, \dots, z_N) + \lambda \max_{1 \leq p \leq P} \frac{f_p(z_1, z_2, \dots, z_N)}{CL_p}
\tag{Eq. 6'''}$$

[0089] Where λ is a preset constant that specifies the trade-off between the optimization on RMS of the defect size and the optimization on the worst defect size. In particular, if $\lambda=0$, then this becomes Eq.4 and we are only minimizing the RMS of the defect size; while if $\lambda=1$, then this becomes Eq.5 and we are only minimizing the worst defect size; if $0 < \lambda < 1$, then we are taking

both into consideration in the optimization. Such optimization can be solved using multiple methods. For example, we can adjust the weighting in each iteration, similar to the one described previously. Alternatively, similar to minimizing the worst defect size from inequalities, we can view the inequalities of Eq. 6' and 6'' as constraints of the design variables during solution of the quadratic programming problem. Then, we can relax the bounds on the worst defect size incrementally or increase the weight for the worst defect size incrementally, compute the cost function value for every achievable worst defect size, and choose the design variable values that minimize the total cost function as the initial point for the next step. By doing this iteratively, we can achieve the minimization of this new cost function,

[0090] The linear approximation of Eq. 3 only holds in a small vicinity of $(z_{1i}, z_{2i}, \dots, z_{Ni})$.

If $f_p(z_1, z_2, \dots, z_N)$ is highly non-linear to the design variables $(z_1, z_2, \dots, z_N)$, optimization using the linear approximation of Eq. 3 may take too many iterations and/or lead to a local minimum of the cost function $CF(z_1, z_2, \dots, z_N)$ instead of a global minimum. This problem can be alleviated by expanding the cost function $CF(z_1, z_2, \dots, z_N)$ into higher order polynomials of some design variables, especially those to which the cost function is highly non-linear, such as cost functions involving aberrations introduced by the projection optics. Fig. 6 shows an example flow diagram illustrating key steps of the second optimization process. Many of the steps of Fig. 6 are very similar to corresponding steps in Fig. 5, unless explained otherwise here. One major difference is that in step S604, the multi-variable cost function is expressed as a higher-order (such as quadratic) polynomial including fitting coefficients related to, for example, partial derivatives of transmission cross coefficients (TCCs). In step S606 TCC is expanded around starting point for each iteration, and in step S607, aerial image, resist image and edge placement error (EPE) are expanded. The rest of the steps are similar to the corresponding steps described in Fig. 5. From the elucidation above it will be apparent to the skilled person that in a specific embodiment, the number of iterations may even be one, resulting in a single calculation sequence. This may, for example, occur when the description of some design variables initially is sufficient enough that the predefined termination condition is satisfied after the single calculation.

[0091] The example process flow of Fig. 6 is elaborated mathematically below. As an example, $f_p(z_1, z_2, \dots, z_N)$ is expanded as:

$$f_p(z_1, z_2, \dots, z_N) \approx f_p(z_{1i}, z_{2i}, \dots, z_{Ni}) + \sum_{n=1}^N a_{p,n} (z_n - z_{ni}) + \sum_{n_1=1}^N \sum_{n_2=1}^N a_{p,n_1,n_2} (z_{n_1} - z_{n_1i})(z_{n_2} - z_{n_2i}) \quad (\text{Eq. 7}).$$

The coefficients $a_{p,n}$ and a_{p,n_1,n_2} can be fitted from a set of known values of the design variables and be derived as partial derivatives, details of which can be found in commonly assigned U.S. Patent Application Serial No. 12/315,849, disclosure of which is hereby incorporated by
 5 reference in its entirety. The non-linear approximation in Eq. 7 generally holds in a much larger vicinity of $(z_{1i}, z_{2i}, \dots, z_{Ni})$ than that in which the linear approximation of Eq. 3 holds, and thus leads to faster convergence and higher possibility of finding the global minimum, albeit at a higher computational cost. It should be noted that we only use the 2-order polynomial approximation as an example of in this disclosure. It is straightforward to extend the
 10 methodologies to higher-order polynomial approximations or other non-polynomial approximations.

[0092] In a second exemplary optimization process, according to embodiments, relationship between the design variables $(z_1, z_2, \dots, z_N)$ and $f_p(z_1, z_2, \dots, z_N)$ specific to a lithographic projection apparatus is harnessed to accelerate and simplify the optimization process.

15 **[0093]** In one example, the aerial image AI can be expressed as

$$\begin{aligned} AI(x) &= \sum_k \left| A(k) \sum_{k'} M(k' - k) L(k') \exp(-jk'x) \right|^2 \\ &= \sum_k A(k)^2 \left[\sum_{k'} \sum_{k''} M(k' - k) L(k') M^*(k'' - k) L^*(k'') \exp(-j(k' - k'')x) \right] \\ &= \sum_{k'} \sum_{k''} \left[\sum_k A(k)^2 L(k + k') L^*(k + k'') \right] M(k') M^*(k'') \exp(-j(k' - k'')x) \quad (\text{Eq. 8}) \\ &= \sum_{k'} \sum_{k''} TCC_{k',k''} M(k') M^*(k'') \exp(-j(k' - k'')x) \end{aligned}$$

$$\text{wherein } TCC_{k',k''} \equiv \sum_k A(k)^2 L(k + k') L^*(k + k'') \quad (\text{Eq. 9})$$

[0094] Computation cost of $TCC_{k',k''}$ using Eq. 9 can be reduced by applying a Fourier transform to both sides of the Eq. 9:

$$\begin{aligned}
& \sum_{k',k''} TCC_{k',k''} \exp(-j\omega'k' - \omega''k'') \\
&= \sum_{k',k''} \sum_k A(k)^2 L(k+k') L^*(k+k'') \exp(-j\omega'k' - \omega''k'') \\
&= \sum_k \left(A(k)^2 \left(\sum_{k'} L(k+k') \exp(-j\omega'k') \right) \left(\sum_{k''} L^*(k+k'') \exp(-\omega''k'') \right) \right) \\
&= \sum_k \left(A(k)^2 \exp(j(\omega' + \omega'')k) \left(\sum_{k'} L(k+k') \exp(-j\omega'(k+k')) \right) \left(\sum_{k''} L^*(k+k'') \exp(-\omega''(k+k'')) \right) \right) \\
&= \Psi_{A^2}(\omega' + \omega'') \Psi_P(\omega') \Psi_P^*(-\omega'')
\end{aligned}$$

(Eq. 9'),

[0095] wherein Ψ_{A^2} and Ψ_P are the Fourier transform of $A(k)$ and $L(k)$, respectively. In

Eq. 9', the summation over (k', k'') becomes a simple multiplication. $TCC_{k',k''}$ can be viewed
 5 as an inverse Fourier transform of Eq. 9'. More details can be found in "Fast TCC Algorithm for the Model Building of High NA Lithography Simulation," by Roderick Köhle, Optical Microlithography XVIII, Proceedings of SPIE, Vol. 5754, 918-929, which is hereby incorporated by reference in its entirety.

[0096] $AI(x)$ is the aerial image in the space domain. $A(k)$ is the source amplitude from
 10 point k on the source pupil plane. $L(k)$ is the projection optics amplitude and phase function for point k on the lens pupil plane. The projection optics function in the space domain represents distortions caused by the projection optics to the light passing through the projection optics (e.g., distortions in amplitude, phase or both) as a function of location. $M(k)$ is the mask function (i.e., design layout function) in the spatial frequency domain, and can be obtained from the mask
 15 function in the space domain by a Fourier transform. The mask function in the space domain represents distortions caused by the mask to the light passing through the mask (e.g., distortions in amplitude, phase or both) as a function of location. More details can be found in, for example, in U.S. Patent No. 7,587,704, which is incorporated by reference in its entirety. A function in the space domain can be transformed to a corresponding function in the spatial frequency domain
 20 and vice versa by Fourier transform. Here, x and k are both vectors. It is further noted that although in the given example, Eq. 8 is derived from a scalar imaging model, this formalism can also be extended to a vector imaging model, where TE and TM or other polarized light

components are summed separately. $TCC_{k',k''}$, also called the Transmission Cross Coefficient, as defined in Eq. 9, can be viewed as a matrix, which includes optical properties of the lithographic projection apparatus excluding the mask.

[0097] Computation of the aerial image using Eq. 8 can be simplified if only dominant eigenvalues of the $TCC_{k',k''}$ are used. Specifically, when the $TCC_{k',k''}$ is diagonalized and on the largest R eigenvalues are retained, the $TCC_{k',k''}$ can be approximated as:

$$TCC_{k',k''} = \sum_{r=1}^R \lambda_r \phi_r(k') \phi_r^*(k'') \quad (\text{Eq. 9})$$

wherein λ_r ($r=1, \dots, R$) are the R largest eigenvalues and ϕ_r is the eigenvector corresponding to the eigenvalue λ_r .

[0098] Plugging Eq. 9 into Eq. 8,

$$\begin{aligned} AI(x) &= \sum_{k'} \sum_{k''} TCC_{k',k''} M(k') M^*(k'') \exp(-j(k'-k'')x) \\ &= \sum_{k'} \sum_{k''} \sum_{r=1}^R \lambda_r \phi_r(k') \phi_r^*(k'') M(k') M^*(k'') \exp(-j(k'-k'')x) \\ &= \sum_{r=1}^R \lambda_r \sum_{k'} \phi_r(k') M(k') \exp(-jk'x) \sum_{k''} \phi_r^*(k'') M^*(k'') \exp(jk''x) \quad (\text{Eq. 10}) \\ &= \sum_{r=1}^R \lambda_r |\Phi_r(x)|^2 \end{aligned}$$

wherein $\Phi_r(x) \equiv \sum_{k'} \phi_r(k') M(k') \exp(-jk'x)$.

[0099] It is noted that Eq. 10 is exact when all terms are retained in the eigenseries expansion, i.e., when R is equal to the rank of the TCC matrix.

[00100] The $TCC_{k',k''}$ matrix has a fixed relationship to the design variables. Once the $TCC_{k',k''}$ as a function of the design variables are known, the aerial image $AI(x)$, the resist image, the $f_p(z_1, z_2, \dots, z_N)$ and the cost function can be computed by using Eq. 8, the resist model, the specific definition of $f_p(z_1, z_2, \dots, z_N)$ and the specific definition of the

cost function (e.g. Eqs. 1, 5 and 6). Values of the design variables that minimize the cost function can then be found by using the methods described above such as the Gauss-Newton method. Computing the $TCC_{k',k''}$ as a function of the design variables, however, can entail significant computation cost, especially on the summation over k in Eq. 9.

- 5 [00101] We next use the design variables from projection optics which only affect the projection optics function as an example to illustrate how to speed up the fitting process. In a practical lithographic projection apparatus, the $TCC_{k',k''}$ can be well approximated as

$$\begin{aligned} TCC_{k',k''}(z_1, z_2, \dots, z_N) \approx \\ TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0}) + \sum_{n=1}^N a_{TCC,k',k'',n}(z_n - z_{n0}) \\ + \sum_{n_1=1}^N \sum_{n_2=1}^N a_{TCC,k',k'',n_1,n_2}(z_{n_1} - z_{n_10})(z_{n_2} - z_{n_20}) \end{aligned} \quad (\text{Eq. 11}).$$

- 10 [00102] $TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0})$, $a_{TCC,k',k'',n}$ and a_{TCC,k',k'',n_1,n_2} are

independent from the design variables. Therefore, once $TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0})$,

$a_{TCC,k',k'',n}$ and a_{TCC,k',k'',n_1,n_2} are computed, $TCC_{k',k''}(z_1, z_2, \dots, z_N)$ as a function of the design variables are known. $TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0})$ can be directly calculated

from the nominal condition $(z_{10}, z_{20}, \dots, z_{N0})$. The coefficients $a_{TCC,k',k'',n}$ and

- 15 a_{TCC,k',k'',n_1,n_2} can be fitted from a set of know values of the design variables or be derived as partial derivatives, details of which can be found in commonly assigned U.S. Patent Application Serial No. 12/315,849, disclosure of which is hereby incorporated by reference in its entirety.

Among all the $TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0})$, $a_{TCC,k',k'',n}$ and a_{TCC,k',k'',n_1,n_2} ,

$$\frac{N(N+1)}{2} + N + 1 \text{ are independent, since } a_{TCC,k',k'',n_1,n_2} = a_{TCC,k',k'',n_2,n_1}.$$

[00103] Once $TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0})$, $a_{TCC,k',k'',n}$ and a_{TCC,k',k'',n_1,n_2} are computed, the computation of the aerial image AI can be further simplified from Eq. 10 using an expansion with respect to the design variables $(z_1, z_2, \dots, z_N)$:

$$AI(z_1, z_2, \dots, z_N) \approx AI(z_{10}, z_{20}, \dots, z_{N0}) + \sum_{n=1}^N a_{I,n}(z_n - z_{n0}) + \sum_{n_1=1}^N \sum_{n_2=1}^N a_{I,n_1,n_2}(z_{n_1} - z_{n_10})(z_{n_2} - z_{n_20}) \quad (\text{Eq. 12}).$$

5 Each term on the right side of Eq. 12 is referred to as pseudo-aerial images. There are total $1 + N + N^2$ pseudo-aerial images, among which $\frac{N(N+1)}{2} + N + 1$ are independent.

[00104] Plugging Eq. 11 into Eq. 8,

$$\begin{aligned} AI(z_1, z_2, \dots, z_N, x) &= \sum_{k'} \sum_{k''} TCC_{k',k''}(z_1, z_2, \dots, z_N) M(k') M^*(k'') \exp(-j(k' - k'')x) \\ &= \sum_{k'} \sum_{k''} \left[TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0}) + \sum_{n=1}^N a_{TCC,k',k'',n}(z_n - z_{n0}) \right. \\ &\quad \left. + \sum_{n_1=1}^N \sum_{n_2=1}^N a_{TCC,k',k'',n_1,n_2}(z_{n_1} - z_{n_10})(z_{n_2} - z_{n_20}) \right] \\ &\quad M(k') M^*(k'') \exp(-j(k' - k'')x) \\ &= \sum_{k'} \sum_{k''} [TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0})] M(k') M^*(k'') \exp(-j(k' - k'')x) + \\ &\quad \sum_{k'} \sum_{k''} \left[\sum_{n=1}^N a_{TCC,k',k'',n}(z_n - z_{n0}) \right] M(k') M^*(k'') \exp(-j(k' - k'')x) + \\ &\quad \sum_{k'} \sum_{k''} \left[\sum_{n_1=1}^N \sum_{n_2=1}^N a_{TCC,k',k'',n_1,n_2}(z_{n_1} - z_{n_10})(z_{n_2} - z_{n_20}) \right] M(k') M^*(k'') \exp(-j(k' - k'')x) \\ &= \sum_{k'} \sum_{k''} [TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0})] M(k') M^*(k'') \exp(-j(k' - k'')x) + \\ &\quad \sum_{n=1}^N \left[\sum_{k'} \sum_{k''} a_{TCC,k',k'',n} M(k') M^*(k'') \exp(-j(k' - k'')x) \right] (z_n - z_{n0}) + \\ &\quad \sum_{n_1=1}^N \sum_{n_2=1}^N \left[\sum_{k'} \sum_{k''} a_{TCC,k',k'',n_1,n_2} M(k') M^*(k'') \exp(-j(k' - k'')x) \right] (z_{n_1} - z_{n_10})(z_{n_2} - z_{n_20}) \\ &\quad (\text{Eq. 13}). \end{aligned}$$

10 [00105] Comparing Eq. 12 and Eq. 13, it can be seen that each pseudo-aerial image can be computed from $TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0})$ or one of the coefficients $a_{TCC,k',k'',n}$ and

$a_{TCC, k', k'', n_1, n_2}$. Namely,

$$a_{I, n} = \sum_{k'} \sum_{k''} a_{TCC, k', k'', n} M(k') M^*(k'') \exp(-j(k' - k'')x); \quad (\text{Eq. 14})$$

$$a_{I, n_1, n_2} = \sum_{k'} \sum_{k''} a_{TCC, k', k'', n_1, n_2} M(k') M^*(k'') \exp(-j(k' - k'')x) \quad (\text{Eq. 15}).$$

[00106] $TCC_{k', k''}(z_{10}, z_{20}, \dots, z_{N0})$, $a_{TCC, k', k'', n}$ and $a_{TCC, k', k'', n_1, n_2}$ can be fitted from a

5 plurality of $TCC_{l, k', k''}$ of the lithographic projection apparatus respectively under L

distinctive sets of values of the design variables $(z_1, z_2, \dots, z_N)$. $TCC_{l, k', k''}$ is defined as

$$TCC_{l, k', k''} \equiv TCC_{k', k''} \Big|_{z_i = p_{li}}, \text{ wherein } p_{li} \text{ is the value of } z_i \text{ in the } l\text{-th set of values of the design}$$

variables, $i = 1, \dots, N$, $l = 1, \dots, L$. Note that $TCC_{l, k', k''}$ are not functions of the design

variables $(z_1, z_2, \dots, z_N)$. A fitting error (FER) can be defined in any suitable form. The fitting

10 process is to find $TCC_{k', k''}(z_{10}, z_{20}, \dots, z_{N0})$, $a_{TCC, k', k'', n}$ and $a_{TCC, k', k'', n_1, n_2}$ that

minimize the fitting error (FER). An exemplary fitting error (FER) is shown below:

FER

$$= \sum_{l=1}^L \left(TCC_{k', k''}(z_{10}, z_{20}, \dots, z_{N0}) + \sum_{n=1}^N (p_{ln} - z_{n0}) a_{TCC, k', k'', n} \right. \\ \left. + \sum_{n_1=1}^N \sum_{n_2=1}^N (p_{ln_1} - z_{n_10})(p_{ln_2} - z_{n_20}) a_{TCC, k', k'', n_1, n_2} - TCC_{l, k', k''} \right)^2$$

(Eq. 16).

The nominal condition $(z_{10}, z_{20}, \dots, z_{N0})$ can be empirically determined to give acceptable

15 performance to the lithographic projection apparatus. $TCC_{k', k''}(z_{10}, z_{20}, \dots, z_{N0})$ can be

directly computed from $(z_{10}, z_{20}, \dots, z_{N0})$ or be fitted along with $a_{TCC, k', k'', n}$ and $a_{TCC, k', k'', n_1, n_2}$.

We use the TCC computed from $(z_{10}, z_{20}, \dots, z_{N0})$ as an example in the following description.

[00107] L is at least $\frac{N(N+1)}{2} + N + 1$ if $TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0})$ is fitted

with $a_{TCC, k', k'', n}$ and $a_{TCC, k', k'', n_1, n_2}$; L is at least $\frac{N(N+1)}{2} + N$ if

$TCC_{k', k''}(z_{10}, z_{20}, \dots, z_{N0})$ is directly calculated from the nominal condition $(z_{10}, z_{20}, \dots, z_{N0})$,

and only $a_{TCC, k', k'', n}$ and $a_{TCC, k', k'', n_1, n_2}$ are fitted. 2 to 3 times of $\frac{N(N+1)}{2} + N + 1$ may

5 be necessary for L in order to yield desired fitting accuracy. In an exemplary lithographic projection apparatus, N is from about 64 to about 192, and L can be greater than 10000. If this fitting is done directly, at least L $TCC_{l, k', k''}$ ($l=1 \dots L$) are computed as

$$TCC_{l, k', k''} = \sum_k A(k)^2 L_l(k + k') L_l^*(k + k'') \quad (\text{Eq. 17}),$$

10 which requires substantial computation cost and/or storage cost, which may be impractical for a large L , wherein $A(k)$ is the amplitude function of the source, and $L_l(k)$ is the projection optics function under the l -th set of values of the design variables.

[00108] A method of computing the coefficients for polynomial expansion of

$TCC_{k', k''}(z_1, z_2, \dots, z_N)$, according to an embodiment, that significantly reduces the computation cost, is detailed below.

15 [00109] The method comprises the following steps. The method starts with selecting L

distinctive sets of values $(p_{l1}, p_{l2}, \dots, p_{lN})$ of the design variables $(z_1, z_2, \dots, z_N)$ wherein p_{ln} is the value of z_n in the l -th set of values of the design variables, $n=1, \dots, N$, $l=1, \dots, L$.

This step is followed by computing a projection optics function $L_l(k)$ for each set of values

$(p_{l1}, p_{l2}, \dots, p_{lN})$, $n=1, \dots, N$, $l=1, \dots, L$. Note that we consider the nominal design variable

20 values $(z_{10}, z_{20}, \dots, z_{N0})$ as the 0-th set of values, i.e., $p_{0i} = z_i$ for all $n=1, \dots, N$. The next step is identifying the relationship between the projection optics function $L(k)$ and the design variables. We use a linear phase relationship (e.g., the Zernike design variables) as a non-limiting example hereafter. For a linear phase relationship, identifying the relationship is equivalent to identifying a plurality of functions $P_n(k)$ ($n=1 \dots N$) that are the impulse responses of the

design variables. That is, if the projection optics function is $L_0(k)$ when the design variables take the nominal values $(z_{10}, z_{20}, \dots, z_{N0})$, then when the design variables take the values

$(p_{11}, p_{12}, \dots, p_{1N})$, the projection optics function becomes:

$$L_l(k) = L_0(k) \prod_{n=1}^N \exp(j(q_{1n} - z_{n0})P_n(k)) \quad (\text{Eq. 18}),$$

- 5 **[00110]** The following step involves computing $a_{TCC,k',k'',n}$ and a_{TCC,k',k'',n_1,n_2} as linear combinations of $TCC_{l,k',k''}$ ($l=1 \dots L$) in a form of

$$a_{TCC,k',k'',n} = \sum_{l=0}^L h_{l,n} TCC_{l,k',k''} \quad (\text{Eq. 19}) \text{ and}$$

$$a_{TCC,k',k'',n_1,n_2} = \sum_{l=0}^L h_{l,n_1,n_2} TCC_{l,k',k''} \quad (\text{Eq. 20})$$

wherein $h_{l,n}$ and h_{l,n_1,n_2} ($l=0, \dots, L$, $n=1, \dots, N$, $n_1=1, \dots, N$, $n_2=1, \dots, N$) are constants.

- 10 These constants can be solved by minimizing the fitting error FER in Eq. 16. In particular, they are computed by solving linear equations of $a_{TCC,k',k'',n}$ and a_{TCC,k',k'',n_1,n_2} :

$$\frac{\partial FER}{\partial a_{TCC,k',k'',n}} = 0 \text{ and } \frac{\partial FER}{\partial a_{TCC,k',k'',n_1,n_2}} = 0. \text{ As described in the commonly}$$

assigned U.S. Patent Application Serial No. 12/315,849, it can be shown that $a_{TCC,k',k'',n}$ and

a_{TCC,k',k'',n_1,n_2} which minimize Eq. 16 can always be expressed in a form of Eq. 19 and Eq.

- 15 20. The next step is computing

$$\begin{aligned}
& TCC_{k',k''}(z_1, z_2, \dots, z_N) \approx \\
& TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0}) + \sum_{n=1}^N a_{TCC, k', k'', n}(z_n - z_{n0}) \\
& + \sum_{n_1=1}^N \sum_{n_2=1}^N a_{TCC, k', k'', n_1, n_2}(z_{n_1} - z_{n_10})(z_{n_2} - z_{n_20}).
\end{aligned}$$

(Eq. 20')

[00111] The following Eq. 21 and Eq. 22 are derived by plugging Eq. 18 into Eq. 17 and then into Eq. 19 and Eq. 20, respectively,

$$a_{TCC, k', k'', n} = \sum_{l=1}^L h_{l,n} TCC_{l, k', k''} = \sum_{l=1}^L h_{l,n} \sum_k \left(\frac{A(k)^2 L_0(k+k') \prod_{n'=1}^N \exp(j(q_{ln'} - z_{n'0}) P_{n'}(k+k')) L_0^*(k+k'')}{\prod_{n'=1}^N \exp(-j(q_{ln'} - z_{n'0}) P_{n'}(k+k''))} \right)$$

5

$$= \sum_k \left(A(k)^2 L_0(k+k') L_0^*(k+k'') \sum_{l=1}^L \left(h_{l,n} \prod_{n'=1}^N \exp(j(q_{ln'} - z_{n'0}) (P_{n'}(k+k') - P_{n'}(k+k''))) \right) \right)$$

(Eq. 21)

$$\begin{aligned}
a_{TCC, k', k'', n_1, n_2} &= \sum_{l=1}^L h_{l, n_1, n_2} TCC_{l, k', k''} = \sum_{l=1}^L h_{l, n_1, n_2} \sum_k \left(\frac{A(k)^2 L_0(k+k')}{\prod_{n'=1}^N \exp(j(q_{ln'} - z_{n'0}) P_{n'}(k+k')) L_0^*(k+k'')} \right. \\
&\quad \left. \prod_{n'=1}^N \exp(-j(q_{ln'} - z_{n'0}) P_{n'}(k+k'')) \right) \\
&= \sum_k \left(A(k)^2 L_0(k+k') L_0^*(k+k'') \sum_{l=1}^L \left(h_{l, n_1, n_2} \prod_{n'=1}^N \exp(j(q_{ln'} - z_{n'0}) (P_{n'}(k+k') - P_{n'}(k+k''))) \right) \right)
\end{aligned}$$

(Eq. 22).

[00112] Note that $\sum_{l=1}^L \left(h_{l,n} \prod_{n'=1}^N \exp(j(q_{ln'} - z_{n'0})(P_{n'}(k+k') - P_{n'}(k+k''))) \right)$ and $\sum_{l=1}^L \left(h_{l,n_1,n_2} \prod_{n'=1}^N \exp(j(q_{ln'} - z_{n'0})(P_{n'}(k+k') - P_{n'}(k+k''))) \right)$ are only functions of k, k'

and k'' and can be computed prior to the summation over k in Eq. 21 and Eq. 22. The

summation of Eq. 21 or Eq.22 over k is done only once for each $a_{TCC,k',k'',n}$ and a_{TCC,k',k'',n_1,n_2} .

5 In total, only at most $\frac{N(N+1)}{2} + N + 1$ summations over k are need to compute each $a_{TCC,k',k'',n}$

and a_{TCC,k',k'',n_1,n_2} . This significantly reduces the computation cost compared to

computation of L $TCC_{l,k',k''}$, each of which requires a summation in Eq. 9 over k , wherein L

can be 2 to 3 times of $\frac{N(N+1)}{2} + N + 1$.

[00113] The computation cost can be further decreased by applying a Fourier transform (e.g.,

10 a fast Fourier transform algorithm) to both sides of each of Eqs. 21-22, similar to Eq. 9'.

[00114] As we mentioned previously, $P_n(k)$ can be the Zernike polynomials. The Zernike polynomials include even Zernike polynomials and odd Zernike polynomials. The even Zernike polynomials are defined as $Z_n^m(\rho, \varphi) = R_n^m(\rho) \cos(m\varphi)$; the odd Zernike polynomials are defined as $Z_n^{-m}(\rho, \varphi) = R_n^m(\rho) \sin(m\varphi)$, where m and n are nonnegative integers with $n \geq m$, φ is the

15 azimuthal angle, and ρ is the radial distance, $0 \leq \rho \leq 1$. The radial polynomials $R_n^m(\rho)$ are defined

as $R_n^m(\rho) = \sum_{k=0}^{(n-m)/2} \frac{(-1)^k (n-k)!}{k!((n+m)/2-k)!((n-m)/2-k)!} \rho^{n-2k}$ when $(n-m)$ is even, and are

identically 0 when $(n-m)$ is odd. For $m = 0$, the even definition of the Zernike polynomials is used which reduces to $R_n^0(\rho)$.

[00115] An alternative method of computing $TCC_{k',k''}(z_1, z_2, \dots, z_N)$, according to another

20 embodiment, that also significantly reduces the computation cost, is detailed below.

[00116] The method comprises the following steps. The first step is identifying the relationship between the projection optics function $L(k)$ and the design variables. We again use

a linear phase relationship (e.g., the Zernike design variables) as a non-limiting example thereafter, thus Eq. 18 describes the response of the projection optics function from the design variables. The next step is computing each $a_{TCC,k',k'',n}$ and a_{TCC,k',k'',n_1,n_2} using Eq. 23, Eq. 24 and Eq. 25 shown below:

$$a_{TCC,k',k'',n} = \sum_k (jA(k)^2 L_0(k+k') L_0^*(k+k'') (P_n(k+k') - P_n(k+k''))) \quad (\text{Eq. 23})$$

$$a_{TCC,k',k'',n,n} = -\frac{1}{2} \sum_k (jA(k)^2 L_0(k+k') L_0^*(k+k'') (P_n(k+k') - P_n(k+k''))^2), \text{ for any}$$

$$n_1 = n_2 = n \quad (\text{Eq. 24}),$$

$$a_{TCC,k',k'',n_1,n_2} = -\sum_k (jA(k)^2 L_0(k+k') L_0^*(k+k'') (P_{n_1}(k+k') - P_{n_1}(k+k'')) (P_{n_2}(k+k') - P_{n_2}(k+k'')))$$

for any $n_1 \neq n_2$ (Eq. 25).

The next step is computing

$$TCC_{k',k''}(z_1, z_2, \dots, z_N) \approx TCC_{k',k''}(z_{10}, z_{20}, \dots, z_{N0}) + \sum_{n=1}^N a_{TCC,k',k'',n} (z_n - z_{n0}) + \sum_{n_1=1}^N \sum_{n_2=1}^N a_{TCC,k',k'',n_1,n_2} (z_{n_1} - z_{n_10}) (z_{n_2} - z_{n_20}).$$

(Eq. 25')

[00117] In the computation of each $a_{TCC,k',k'',n}$ and a_{TCC,k',k'',n_1,n_2} , the summation of

Eqs. 23-25 over k is done only once. In total, only at most $\frac{N(N+1)}{2} + N + 1$ summations over k

are needed to compute each $a_{TCC,k',k'',n}$ and a_{TCC,k',k'',n_1,n_2} .

[00118] The computation cost can be further decreased by applying a Fourier transform (e.g., a fast Fourier transform algorithm) to both sides of each of Eqs. 23-25, similar to Eq. 9'.

[00119] Eq. 23, Eq. 24 and Eq. 25 are derived by considering $a_{TCC,k',k'',n}$ and

a_{TCC,k',k'',n_1,n_2} as Taylor expansion coefficients of $TCC_{k',k''}(z_1, z_2, \dots, z_N)$ rather than the

fitting coefficients disclosed in Eq. 19 and Eq.20. By Taylor expansion, $a_{TCC,k',k'',n}$ and

a_{TCC,k',k'',n_1,n_2} then become the first-order and second-order partial derivatives, respectively.

In particular, we plug Eq. 9 into partial derivatives of $TCC_{k',k''}$, then plug

$$L(k) = L_0(k) \prod_{n=1}^N \exp(j(q_n - z_{n0})P_n(k)) \quad (\text{Eq. 26}), \text{ and}$$

5 :

$$\begin{aligned} a_{TCC,k',k'',n} &= \left. \frac{\partial TCC_{k',k''}}{\partial z_n} \right|_{(z_{10}, z_{20}, \dots, z_{N0})} = \left. \frac{\partial \sum_k A(k)^2 L(k+k') L^*(k+k'')}{\partial z_n} \right|_{(z_{10}, z_{20}, \dots, z_{N0})} \\ &= \frac{\partial}{\partial z_n} \left(\sum_k \left(\prod_{n_1=1}^N \exp(j(q_{n_1} - z_{n0})(P_{n_1}(k+k') - P_{n_1}(k+k''))) \right) \right) \bigg|_{(z_{10}, z_{20}, \dots, z_{N0})} ; \\ &= \sum_k (jA(k)^2 L_0(k+k') L_0^*(k+k'') (P_n(k+k') - P_n(k+k''))) \end{aligned} \quad (\text{Eq. 26'})$$

26')

$$\begin{aligned} a_{TCC,k',k'',n,n} &= \left. \frac{\partial^2 TCC_{k',k''}}{\partial z_n^2} \right|_{(z_{10}, z_{20}, \dots, z_{N0})} = \left. \frac{\partial^2 \sum_k A(k)^2 L(k+k') L^*(k+k'')}{\partial z_n^2} \right|_{(z_{10}, z_{20}, \dots, z_{N0})} \\ &= \frac{1}{2} \frac{\partial^2}{\partial z_n^2} \left(\sum_k \left(\prod_{n_1=1}^N \exp(j(q_{n_1} - z_{n0})(P_{n_1}(k+k') - P_{n_1}(k+k''))) \right) \right) \bigg|_{(z_{10}, z_{20}, \dots, z_{N0})} \\ &= -\frac{1}{2} \sum_k (jA(k)^2 L_0(k+k') L_0^*(k+k'') (P_n(k+k') - P_n(k+k''))^2) \end{aligned} \quad (\text{Eq. 26''})$$

10 ;

$$a_{TCC,k',k'',n_1,n_2} = \frac{\partial^2 TCC_{k',k''}}{\partial z_{n_1} \partial z_{n_2}} \bigg|_{(z_{10}, z_{20}, \dots, z_{N0})} = \frac{\partial^2 \sum_k A(k)^2 L(k+k') L^*(k+k'')}{\partial z_{n_1} \partial z_{n_2}} \bigg|_{(z_{10}, z_{20}, \dots, z_{N0})}$$

$$= - \sum_k (jA(k)^2 L_0(k+k') L_0^*(k+k'') (P_{n_1}(k+k') - P_{n_1}(k+k'')) (P_{n_2}(k+k') - P_{n_2}(k+k'')))$$

. (Eq. 26''')

[00120] Optimizing a lithographic projection apparatus can expand the process window. A larger process window provides more flexibility in process design and chip design. The process window can be defined as a set of focus and dose values for which the resist image are within a certain limit of the design target of the resist image. Note that all the methods discussed here may also be extended to a generalized process window definition that can be established by different or additional base parameters in addition to exposure dose and defocus. These may include, but are not limited to, optical settings such as NA, sigma, aberrations, polarization, or optical constants of the resist layer (whose effects on the imaging process are included in the optical model, i.e. the TCCs). For example, as described earlier, if the PW also consists of different mask bias, then the optimization includes the minimization of MEEF (Mask Error Enhancement Factor), which is defined as the ratio between the wafer EPE and the induced mask edge bias. The process window defined on focus and dose values only serve as an example in this disclosure. A method of maximizing the process window, according to an embodiment, is described below.

[00121] In a first step, starting from a known condition (f_0, ε_0) in the process window, wherein f_0 is a nominal focus and ε_0 is a nominal dose, minimizing one of the cost functions below in the vicinity $(f_0 \pm \Delta f, \varepsilon_0 \pm \Delta \varepsilon)$:

$$CF(z_1, z_2, \dots, z_N, f_0, \varepsilon_0) = \max_{(f, \varepsilon) = (f_0 \pm \Delta f, \varepsilon_0 \pm \Delta \varepsilon)} \max_p |f_p(z_1, z_2, \dots, z_N, f, \varepsilon)|$$

(Eq. 27).

or

$$CF(z_1, z_2, \dots, z_N, f_0, \varepsilon_0) = \sum_{(f, \varepsilon) = (f_0 \pm \Delta f, \varepsilon_0 \pm \Delta \varepsilon)} \sum_p w_p f_p^2(z_1, z_2, \dots, z_N, f, \varepsilon) \quad (\text{Eq. 27'})$$

or

$$\begin{aligned}
CF(z_1, z_2, \dots, z_N, f_0, \varepsilon_0) = & \\
(1 - \lambda) \sum_{(f, \varepsilon) = (f_0 \pm \Delta f, \varepsilon_0 \pm \Delta \varepsilon)} \sum_p w_p f_p^2(z_1, z_2, \dots, z_N, f, \varepsilon) & \\
+ \lambda \max_{(f, \varepsilon) = (f_0 \pm \Delta f, \varepsilon_0 \pm \Delta \varepsilon)} \max_p |f_p(z_1, z_2, \dots, z_N, f, \varepsilon)| & \\
\text{(Eq.27'')} &
\end{aligned}$$

[00122] If the nominal focus f_0 and nominal dose ε_0 are allowed to shift, they can be optimized jointly with the design variables $(z_1, z_2, \dots, z_N)$. In the next step, $(f_0 \pm \Delta f, \varepsilon_0 \pm \Delta \varepsilon)$ is accepted as part of the process window, if a set of values of $(z_1, z_2, \dots, z_N, f, \varepsilon)$ can be found such that the cost function is within a preset limit.

[00123] Alternatively, if the focus and dose are not allowed to shift, the design variables $(z_1, z_2, \dots, z_N)$ are optimized with the focus and dose fixed at the nominal focus f_0 and nominal dose ε_0 . In an alternative embodiment, $(f_0 \pm \Delta f, \varepsilon_0 \pm \Delta \varepsilon)$ is accepted as part of the process window, if a set of values of $(z_1, z_2, \dots, z_N)$ can be found such that the cost function is within a preset limit.

[00124] The methods described earlier in this disclosure can be used to minimize the respective cost functions of Eqs. 27, 27', or 27''. If the design variables are characteristics of the projection optics, such as the Zernike coefficients, then minimizing the cost functions of Eqs. 27, 27', or 27'' leads to process window maximization based on projection optics optimization, i.e., Lens Optimization (LO). If the design variables are characteristics of the source and mask in addition to those of the projection optics, then minimizing the cost function of Eqs. 27, 27', or 27'' leads to process window maximizing based on simultaneous Source-Mask-Lens-Optimization (SMLO), as illustrated in Fig. 3.

[00125] Alternatively, when a lithographic projection apparatus works at a fixed nominal condition (f_0, ε_0) in the process window, the actual focus f and dose ε can deviate from the nominal focus f_0 and the nominal dose ε_0 . The distribution of the focus f and dose ε can follow a distribution (e.g. Gaussian distribution) around (f_0, ε_0) . The design variables can be optimized to minimize the probability that the resist image (e.g., solubility of the resist in the resist layer) at any evaluation point p (RI_p) falls out of a permitted range $[T_1, T_2]$. More details can be found in

commonly assigned U.S. Patent Application Serial No. 12/642,436, the disclosure of which is hereby incorporated by reference in its entirety.

[00126] Mathematically, the goal of this optimization is to find a set of values of the design variables $(z_1, z_2, \dots, z_N)$ that minimize

$$\max_p \max_{RI \in [T_1, T_2]} \max_{f, \varepsilon} P(f, \varepsilon) \quad (\text{Eq. 28}),$$

wherein $P(f, \varepsilon)$ is a probability density function of the actual focus f and dose ε .

[00127] For example, if the focus f and dose ε follow a Gaussian distribution, with a standard deviation of f as σ_f and a standard deviation of ε as σ_ε , the probability density function of (f, ε) is

$$P(f, \varepsilon) = \frac{1}{2\pi\sigma_f\sigma_\varepsilon} \exp\left(-\frac{1}{2}\left(\left(\frac{f-f_0}{\sigma_f}\right)^2 + \left(\frac{\varepsilon-\varepsilon_0}{\sigma_\varepsilon}\right)^2\right)\right) \quad (\text{Eq. 29}).$$

[00128] Here, we assume that the focus f and dose ε are independent. However, other distributions (even non-Gaussian distributions), thus other probability density functions, are also possible.

[00129] In this example, minimizing Eq. 28 is equivalent to maximize

$$\min_p \min_{RI \in [T_1, T_2]} \min_{f, \varepsilon} \left(\left(\frac{f-f_0}{\sigma_f} \right)^2 + \left(\frac{\varepsilon-\varepsilon_0}{\sigma_\varepsilon} \right)^2 \right) \quad (\text{Eq. 29'}).$$

[00130] The resist image at the evaluation point p , RI_p , is a function of the design variables $(z_1, z_2, \dots, z_N)$ and the actual focus f and dose ε . RI_p can be expanded around the nominal condition (f_0, ε_0) as:

$$\begin{aligned} & RI_p(z_1, z_2, \dots, z_N, f, \varepsilon) \\ &= RI_p(z_{10}, z_{20}, \dots, z_{N0}, f_0, \varepsilon_0) + (\varepsilon - \varepsilon_0)a_{p,\varepsilon} \\ &+ (1 + \varepsilon - \varepsilon_0)(a_{p,1f_z}(z_1, z_2, \dots, z_N)(f - f_0) + a_{p,2f}(f - f_0)^2 + a_{p,2z}(z_1, z_2, \dots, z_N)) \end{aligned} \quad (\text{Eq. 30}).$$

Since the relationship between RI and the dose ε is essentially linear and the dose ε does not typically deviate from ε_0 more than 10%, the quadratic term of the dose ε is omitted. Plugging Eq.

30 into Eq. 29 and approximating $1 + (\varepsilon - \varepsilon_0) \approx \frac{1}{1 - (\varepsilon - \varepsilon_0)}$, as $(\varepsilon - \varepsilon_0) \ll 1$, Eq. 29' can be

further simplified as:

$$\min_p \min_{RI \in [T_1, T_2]} \min_f \left(\left(\frac{f - f_0}{\sigma_f} \right)^2 + \left(\frac{a_{p,1fz}(z_1, z_2, \dots, z_N)(f - f_0) + a_{p,2f}(f - f_0)^2 + a_{p,2z}(z_1, z_2, \dots, z_N) + a_{p,\epsilon}}{RI_p(z_{10}, z_{20}, \dots, z_{N0}, f_0, \epsilon_0) - a_{p,\epsilon} - RI_p(z_1, z_2, \dots, z_N, f, \epsilon)} \sigma_\epsilon - \frac{1}{\sigma_\epsilon} \right)^2 \right) \quad (\text{Eq. 31}).$$

[00131] The methods described earlier in this disclosure can be used to minimize Eq. 31. If the design variables are characteristics of the projection optics, such as the Zernike coefficients, then minimizing Eq. 31 leads to process window maximization based on projection optics optimization.

[00132] A method of maximizing the process window according to an embodiment, thus comprises finding values of the design variables that minimize the maximum value of the probability that the resist image (e.g., solubility of the resist in the resist layer) at any evaluation point p (RI_p) falls out of a permitted range.

[00133] Fig. 7 shows one specific example of how a simultaneous SMLO process can use a Gauss Newton Algorithm for optimization. In step S702, starting values of design variables are identified. Tuning ranges for each variable may also be identified. In step S704, the cost function is defined using the design variables. In step S706 cost function is expanded around the starting values for all evaluation points in the design layout. In optional step S710, a full-chip simulation is executed to cover all critical patterns in a full-chip design layout. Desired lithographic response metric (such as CD or EPE) is obtained in step S714, and compared with predicted values of those quantities in step S712. In step S716, a process window is determined. Steps S718, S720, and S722 are similar to corresponding steps S514, S516 and S518, as described with respect to Fig. 5. As mentioned before, the final output may be a wavefront aberration map in the pupil plane, optimized to produce the desired imaging performance. The final output may also be an optimized source map and/or an optimized design layout.

[00134] As stated above, the cost function is not limited to a particular form such as Eq. 1.

The cost function thus can be generalized as $CF(z_1, z_2, \dots, z_N) = \sum_{p=1}^P LM_p$, (Eq. 100), wherein

LM_p is the p -th evaluation point. A large number of evaluation points in the lithographic projection system can lead to complexity of the cost function and high computation cost in minimizing the cost function. A method of reducing the number of evaluation points while

maintaining the effectiveness of the optimization is desirable. Such a method is disclosed in commonly assigned U.S. Patent Application Serial No. 2011/0107280, filed on October 28, 2010, which is hereby incorporated by reference in its entirety.

[00135] Each evaluation point LM_p is a function of the design variables $(z_1, z_2, \dots, z_N)$.

5 Again, the design variables $(z_1, z_2, \dots, z_N)$ can comprise any characteristics of the lithographic projection apparatus, including those of the source, the mask, and the projection optics. In an embodiment, at least some of the evaluation points are associated with one or more features in a design layout. A gradient of evaluation point LM_p with respect to a design variable z_i measures the sensitivity of that evaluation point LM_p to changes of the design variable z_i .

10 This gradient can be mathematically expressed as $\frac{\partial LM_p}{\partial z_i}$, (Eq. 101). If an evaluation point

LM_p is insensitive to changes of z_i , i.e., $\frac{\partial LM_p}{\partial z_i}$ is small, this evaluation point LM_p may be

eliminated from the cost function without severely affecting the effectiveness of the optimization. If several evaluation points have similar gradients, not all (e.g., one) of these evaluation points may be kept in the cost function while the rest of these evaluation points eliminated from the cost
15 function without severely affecting the effectiveness of the optimization.

[00136] According to an embodiment illustrated in Fig. 8, a plurality of evaluation points may be identified in step S801; a gradient of each of the plurality of evaluation points with respect to a design variable is calculated in step S802; a subset of evaluation points is selected from the plurality of evaluation points is selected based on the gradient.

20 **[00137]** In an embodiment, gradients of an evaluation point with respect to more than one design variables $(z_j; j \in [1, 2, \dots, N])$ can be calculated. The more than one design variables can include all or part of $(z_1, z_2, \dots, z_N)$. For example, gradients of an evaluation point LM_p with respect to all design variables associated with the projection optics (e.g., the Zernike design variables). These gradients can be written into a vector form $\vec{v}_p = \left(\frac{\partial LM_p}{\partial z_j}; j \in [1, 2, \dots, N] \right)$, (Eq.

25 102).

[00138] In an embodiment, a characteristic value V_p may be calculated from the gradients in step S803. The characteristic value V_p may be, for example, the magnitude of the vector $\vec{v}_p$, the maximum range of $\vec{v}_p$ across all values of $(z_j; j \in [1, 2, \dots, N])$, or the maximum change of LM_p with respect to the change of $(z_j; j \in [1, 2, \dots, N])$.

5 [00139] In an embodiment, evaluation points with characteristic value V_p within a certain range may be eliminated from the cost function. For example, evaluation points with characteristic value V_p smaller than a threshold may be eliminated from the cost function.

[00140] In an embodiment, the evaluation points may be grouped in step S803 based on the gradients of the evaluation points. In an example illustrated in Fig. 9, correlation between each
10 pair of the evaluation points is calculated in step S901. The correlation between evaluation point

LM_p and evaluation point LM_q can be mathematically expressed as $\frac{\vec{v}_p \cdot \vec{v}_q}{\|\vec{v}_p\| \|\vec{v}_q\|}$, (Eq. 103). In

step S902, if the correlation $\frac{\vec{v}_p \cdot \vec{v}_q}{\|\vec{v}_p\| \|\vec{v}_q\|}$ is above a certain threshold, evaluation point LM_p and

evaluation point LM_q are placed in a same group. In step S903, at least one evaluation point is selected from each group. For example, the evaluation point with the greatest characteristic
15 value V_p is selected from each group. The selected evaluation point from each group form the subset of evaluation points.

[00141] In an example, eight evaluation points $LM_1, LM_2, LM_3, LM_4, LM_5, LM_6, LM_7$, and LM_8 are in the cost function. $V_1=0.43, V_2=0.37, V_3=0.57, V_4=0.72, V_5=0.40, V_6=0.85, V_7=0.71$, and $V_8=0.03$. If all evaluation points with a characteristic value less than 0.1 is eliminated, LM_8
20 is eliminated. Fig. 10 shows correlations among $LM_1, LM_2, LM_3, LM_4, LM_5, LM_6$, and LM_7 . If all evaluation points with correlation of at least 0.8 are grouped together, three groups are formed: $\{LM_1, LM_2\}$, $\{LM_3, LM_4, LM_5\}$, and $\{LM_6, LM_7\}$. From each of these three groups, the evaluation point with greatest characteristic value is selected to form the subset. Therefore, the subset comprises LM_1, LM_4 , and LM_6 .

25 [00142] In another example, at least one evaluation point is selected from each group in step S903, based on their proximity in real space. As illustrated in Fig. 11, three groups 1110, 1120

and 1130 each comprise several evaluation points 1111, 1121 and 1131. The three evaluation points enclosed in area 1150 are the closest in real space and can be selected to be comprised by the subset.

[00143] The method illustrated in Fig. 8 is not limited to optimization but can be used in conjunction with any other suitable algorithms.

[00144] In an embodiment, some of the evaluation points are associated with patterns in the design layout. For example, these evaluation points may be physical points on a resist image. The physical points may be on the edge, inside, or outside the patterns in the resist image.

Selection among these evaluation points to be included in the cost function effectively is selection of patterns of a design layout to be included in downstream algorithms such as SMO or SMLO.

[00145] In one embodiment, the design variables may be associated with the projection optics. For example, the design variables are Zernike coefficients or other adjustable characteristics of the projection optics. The method in Fig. 8 can be used to select evaluation points that are sensitive to design variables associated with the projection optics.

[00146] The embodiments described herein may also be used with other types of apparatuses for imaging a design layout or a portion thereof onto a substrate, for example, with an electron beam lithography apparatus. An apparatus configured to image a design layout or a portion thereof onto a substrate can be generically referred to as a lithographic imaging apparatus.

[00147] Fig. 12 is a block diagram that illustrates a computer system 100 which can assist in implementing the optimization methods and flows disclosed herein. Computer system 100 includes a bus 102 or other communication mechanism for communicating information, and a processor 104 (or multiple processors 104 and 105) coupled with bus 102 for processing information. Computer system 100 also includes a main memory 106, such as a random access memory (RAM) or other dynamic storage device, coupled to bus 102 for storing information and instructions to be executed by processor 104. Main memory 106 also may be used for storing temporary variables or other intermediate information during execution of instructions to be executed by processor 104. Computer system 100 further includes a read only memory (ROM) 108 or other static storage device coupled to bus 102 for storing static information and instructions for processor 104. A storage device 110, such as a magnetic disk or optical disk, is provided and coupled to bus 102 for storing information and instructions.

[00148] Computer system 100 may be coupled via bus 102 to a display 112, such as a cathode ray tube (CRT) or flat panel or touch panel display for displaying information to a computer user. An input device 114, including alphanumeric and other keys, is coupled to bus 102 for communicating information and command selections to processor 104. Another type of user
5 input device is cursor control 116, such as a mouse, a trackball, or cursor direction keys for communicating direction information and command selections to processor 104 and for controlling cursor movement on display 112. This input device typically has two degrees of freedom in two axes, a first axis (e.g., x) and a second axis (e.g., y), that allows the device to specify positions in a plane. A touch panel (screen) display may also be used as an input device.

[00149] According to one embodiment, portions of the optimization process may be performed by computer system 100 in response to processor 104 executing one or more sequences of one or more instructions contained in main memory 106. Such instructions may be read into main memory 106 from another computer-readable medium, such as storage device 110. Execution of the sequences of instructions contained in main memory 106 causes processor 104
15 to perform the process steps described herein. One or more processors in a multi-processing arrangement may also be employed to execute the sequences of instructions contained in main memory 106. In alternative embodiments, hard-wired circuitry may be used in place of or in combination with software instructions to implement an embodiment. Thus, an embodiment are not limited to any specific combination of hardware circuitry and software.

[00150] The term “computer-readable medium” as used herein refers to any medium that participates in providing instructions to processor 104 for execution. Such a medium may take many forms, including but not limited to, non-volatile media, volatile media, and transmission media. Non-volatile media include, for example, optical or magnetic disks, such as storage device 110. Volatile media include dynamic memory, such as main memory 106. Transmission
25 media include coaxial cables, copper wire and fiber optics, including the wires that comprise bus 102. Transmission media can also take the form of acoustic or light waves, such as those generated during radio frequency (RF) and infrared (IR) data communications. Common forms of computer-readable media include, for example, a floppy disk, a flexible disk, hard disk, magnetic tape, any other magnetic medium, a CD-ROM, DVD, any other optical medium, punch
30 cards, paper tape, any other physical medium with patterns of holes, a RAM, a PROM, and

EPROM, a FLASH-EPROM, any other memory chip or cartridge, a carrier wave as described hereinafter, or any other medium from which a computer can read.

[00151] Various forms of computer readable media may be involved in carrying one or more sequences of one or more instructions to processor 104 for execution. For example, the instructions may initially be borne on a magnetic disk of a remote computer. The remote computer can load the instructions into its dynamic memory and send the instructions over a telephone line using a modem. A modem local to computer system 100 can receive the data on the telephone line and use an infrared transmitter to convert the data to an infrared signal. An infrared detector coupled to bus 102 can receive the data carried in the infrared signal and place the data on bus 102. Bus 102 carries the data to main memory 106, from which processor 104 retrieves and executes the instructions. The instructions received by main memory 106 may optionally be stored on storage device 110 either before or after execution by processor 104.

[00152] Computer system 100 also preferably includes a communication interface 118 coupled to bus 102. Communication interface 118 provides a two-way data communication coupling to a network link 120 that is connected to a local network 122. For example, communication interface 118 may be an integrated services digital network (ISDN) card or a modem to provide a data communication connection to a corresponding type of telephone line. As another example, communication interface 118 may be a local area network (LAN) card to provide a data communication connection to a compatible LAN. Wireless links may also be implemented. In any such implementation, communication interface 118 sends and receives electrical, electromagnetic or optical signals that carry digital data streams representing various types of information.

[00153] Network link 120 typically provides data communication through one or more networks to other data devices. For example, network link 120 may provide a connection through local network 122 to a host computer 124 or to data equipment operated by an Internet Service Provider (ISP) 126. ISP 126 in turn provides data communication services through the worldwide packet data communication network, now commonly referred to as the "Internet" 128. Local network 122 and Internet 128 both use electrical, electromagnetic or optical signals that carry digital data streams. The signals through the various networks and the signals on network link 120 and through communication interface 118, which carry the digital data to and from computer system 100, are exemplary forms of carrier waves transporting the information.

[00154] Computer system 100 can send messages and receive data, including program code, through the network(s), network link 120, and communication interface 118. In the Internet example, a server 130 might transmit a requested code for an application program through Internet 128, ISP 126, local network 122 and communication interface 118. In accordance with an embodiment, one such downloaded application provides for the illumination optimization of the embodiment, for example. The received code may be executed by processor 104 as it is received, and/or stored in storage device 110, or other non-volatile storage for later execution. In this manner, computer system 100 may obtain application code in the form of a carrier wave.

[00155] Fig. 13 schematically depicts an exemplary lithographic projection apparatus whose illumination source could be optimized utilizing the methods described herein. The apparatus comprises:

- a radiation system IL, for supplying a projection beam B of radiation. In this particular case, the radiation system also comprises a radiation source SO;

- a first object table (mask table) MT provided with a mask holder for holding a mask MA (e.g., a reticle), and connected to first positioning means for accurately positioning the mask with respect to item PS;

- a second object table (substrate table) WT provided with a substrate holder for holding a substrate W (e.g., a resist-coated silicon wafer), and connected to second positioning means for accurately positioning the substrate with respect to item PS;

- a projection system ("lens") PS (e.g., a refractive, catoptric or catadioptric optical system) for imaging an irradiated portion of the mask MA onto a target portion C (e.g., comprising one or more dies) of the substrate W.

[00156] As depicted herein, the apparatus is of a transmissive type (i.e., has a transmissive mask). However, in general, it may also be of a reflective type, for example (with a reflective mask). Alternatively, the apparatus may employ another kind of patterning means as an alternative to the use of a mask; examples include a programmable mirror array or LCD matrix.

[00157] The source SO (e.g., a mercury lamp or excimer laser) produces a beam of radiation. This beam is fed into an illumination system (illuminator) IL, either directly or after having traversed conditioning means, such as a beam expander Ex, for example. The illuminator IL may comprise adjusting means AD for setting the outer and/or inner radial extent (commonly referred to as σ -outer and σ -inner, respectively) of the intensity distribution in the beam. In

addition, it will generally comprise various other components, such as an integrator IN and a condenser CO. In this way, the beam B impinging on the mask MA has a desired uniformity and intensity distribution in its cross-section.

[00158] It should be noted with regard to Fig. 13 that the source SO may be within the housing of the lithographic projection apparatus (as is often the case when the source SO is a mercury lamp, for example), but that it may also be remote from the lithographic projection apparatus, the radiation beam that it produces being led into the apparatus (e.g., with the aid of suitable directing mirrors); this latter scenario is often the case when the source SO is an excimer laser (e.g., based on KrF, ArF or F₂ lasing).

[00159] The beam PB subsequently intercepts the mask MA, which is held on a mask table MT. Having traversed the mask MA, the beam B passes through the lens PL, which focuses the beam B onto a target portion C of the substrate W. With the aid of the second positioning means (and interferometric measuring means IF), the substrate table WT can be moved accurately, e.g. so as to position different target portions C in the path of the beam PB. Similarly, the first positioning means can be used to accurately position the mask MA with respect to the path of the beam B, e.g., after mechanical retrieval of the mask MA from a mask library, or during a scan. In general, movement of the object tables MT, WT will be realized with the aid of a long-stroke module (coarse positioning) and a short-stroke module (fine positioning), which are not explicitly depicted in Fig. 13. However, in the case of a wafer stepper (as opposed to a step-and-scan tool) the mask table MT may just be connected to a short stroke actuator, or may be fixed.

[00160] The depicted tool can be used in two different modes:

- In step mode, the mask table MT is kept essentially stationary, and an entire mask image is projected in one go (i.e., a single “flash”) onto a target portion C. The substrate table WT is then shifted in the x and/or y directions so that a different target portion C can be irradiated by the beam PB;

- In scan mode, essentially the same scenario applies, except that a given target portion C is not exposed in a single “flash”. Instead, the mask table MT is movable in a given direction (the so-called “scan direction”, e.g., the y direction) with a speed v, so that the projection beam B is caused to scan over a mask image; concurrently, the substrate table WT is simultaneously moved in the same or opposite direction at a speed $V = Mv$, in which M is the

magnification of the lens PL (typically, $M = 1/4$ or $1/5$). In this manner, a relatively large target portion C can be exposed, without having to compromise on resolution.

[00161] The concepts disclosed herein may simulate or mathematically model any generic imaging system for imaging sub wavelength features, and may be especially useful with emerging imaging technologies capable of producing wavelengths of an increasingly smaller size. Emerging technologies already in use include EUV (extreme ultra violet) lithography that is capable of producing a 193nm wavelength with the use of an ArF laser, and even a 157nm wavelength with the use of a Fluorine laser. Moreover, EUV lithography is capable of producing wavelengths within a range of 20-5nm by using a synchrotron or by hitting a material (either solid or a plasma) with high energy electrons in order to produce photons within this range.

[00162] While the concepts disclosed herein may be used for imaging on a substrate such as a silicon wafer, it shall be understood that the disclosed concepts may be used with any type of lithographic imaging systems, e.g., those used for imaging on substrates other than silicon wafers.

[00163] The invention may further be described using the following clauses:

1. A method for a lithographic process for imaging a portion of a design layout onto a substrate using a lithographic imaging apparatus, the lithographic process having a plurality of design variables, the method comprising:

calculating a gradient of each of a plurality of evaluation points or patterns of the lithographic process, with respect to at least one of the design variables; and

selecting a subset of evaluation points or patterns from the plurality of evaluation points or patterns based on the gradient.

2. The method of clause 1, wherein at least some of the plurality of design variables are associated with an illumination source of the lithographic imaging apparatus, at least some of the plurality of design variables are associated with imaging optics of the lithographic imaging apparatus, and/or at least some of the plurality of design variables are associated with the design layout.

3. The method of clause 1, further comprising grouping the plurality of evaluation points or patterns into a plurality of groups based on the gradient.

4. The method of clause 1, further comprising calculating a characteristic value from the gradient.

5. The method of clause 4, wherein the subset does not include any evaluation point with the characteristic value thereof is smaller than a threshold.
6. The method of clause 1, further comprising calculating correlation between gradients of a pair of evaluation points or patterns in the plurality of evaluation points or patterns.
- 5 7. The method of clause 6, further comprising grouping the plurality of evaluation points or patterns into a plurality of groups based on the correlation.
8. The method of clause 7, wherein a pair of evaluations points with correlation above a threshold are placed in a same group.
9. The method of clause 3 or 7, wherein the subset comprises at least one member selected
10 from each of the plurality of groups.
10. The method of clause 1, further comprising:
defining a cost function of the plurality of design variables, the cost function including the subset of evaluation points or patterns; and
adjusting the design variables until a predefined termination condition is satisfied.
- 15 11. The method of clause 10, wherein the predefined termination condition includes one or more of: minimization of the cost function; maximization of the cost function; reaching a preset number of iterations; reaching a value of the cost function equal to or beyond a preset threshold value; reaching a predefined computation time; and, reaching a value of the cost function within an acceptable error limit.
- 20 12. The method of clause 1, wherein the adjusting of the design variables is performed with constraints dictating the range of at least some of the design variables.
13. The method of clause 1 or 12, wherein at least some of the design variables are under constraints representing physical restrictions in a hardware implementation of the lithographic projection apparatus.
- 25 14. The method of clause 13, wherein the constraints include one or more of: rules governing mask manufacturability, and interdependence between the design variables.
15. The method of clause 1, wherein the plurality of evaluation points or patterns are selected from the following lithographic metrics: edge placement error, critical dimension, resist contour distance, worst defect size, and best focus shift.
- 30 16. The method of clause 9, wherein the at least one member is selected from each of the plurality of groups based on proximity of the at least one member in real space.

17. The method of clause 9, wherein the at least one member is selected from each of the plurality of groups based on a characteristic value calculated from the gradient .

18. The method of clause 10, wherein the adjusting is conducted by a method selected from a group consisting of the Gauss–Newton algorithm, the Levenberg-Marquardt algorithm, the
5 gradient descent algorithm, simulated annealing, solving polynomials, solving a quadratic programming problem and the genetic algorithm.

19. The method of clause 1, wherein the plurality of design variables comprises a Zernike coefficient.

20. A computer program product comprising a computer readable medium having
10 instructions recorded thereon, the instructions when executed by a computer implementing the method of any of the above clauses.

[00164] The descriptions above are intended to be illustrative, not limiting. Thus, it will be apparent to one skilled in the art that modifications may be made to the embodiments as described without departing from the scope of the claims set out below.

WHAT IS CLAIMED IS:

1. A method for a lithographic process for imaging a portion of a design layout onto a substrate using a lithographic imaging apparatus, the lithographic process having a plurality of design variables, the method comprising:
 - calculating a gradient of each of a plurality of evaluation points or patterns of the lithographic process, with respect to at least one of the design variables; and
 - selecting a subset of evaluation points or patterns from the plurality of evaluation points or patterns based on the gradient.
2. The method of Claim 1, wherein at least some of the plurality of design variables are associated with an illumination source of the lithographic imaging apparatus, at least some of the plurality of design variables are associated with imaging optics of the lithographic imaging apparatus, and/or at least some of the plurality of design variables are associated with the design layout.
3. The method of Claim 1, further comprising grouping the plurality of evaluation points or patterns into a plurality of groups based on the gradient.
4. The method of Claim 1, further comprising calculating a characteristic value from the gradient.
5. The method of Claim 1, further comprising calculating correlation between gradients of a pair of evaluation points or patterns in the plurality of evaluation points or patterns.
6. The method of Claim 6, further comprising grouping the plurality of evaluation points or patterns into a plurality of groups based on the correlation.
7. The method of Claim 6, wherein a pair of evaluations points with correlation above a threshold are placed in a same group.

8. The method of Claim 3 or 6, wherein the subset comprises at least one member selected from each of the plurality of groups.

9. The method of Claim 1, further comprising:

5 defining a cost function of the plurality of design variables, the cost function including the subset of evaluation points or patterns; and

adjusting the design variables until a predefined termination condition is satisfied.

10. The method of claim 1, wherein the adjusting of the design variables is performed with
10 constraints dictating the range of at least some of the design variables.

11. The method of Claim 1, wherein the plurality of evaluation points or patterns are selected from the following lithographic metrics: edge placement error, critical dimension, resist contour distance, worst defect size, and best focus shift.

15 **12.** The method of Claim 8, wherein the at least one member is selected from each of the plurality of groups based on proximity of the at least one member in real space.

13. The method of Claim 8, wherein the at least one member is selected from each of the
20 plurality of groups based on a characteristic value calculated from the gradient.

14. The method of Claim 9, wherein the adjusting is conducted by a method selected from a group consisting of the Gauss–Newton algorithm, the Levenberg-Marquardt algorithm, the gradient descent algorithm, simulated annealing, solving polynomials, solving a quadratic
25 programming problem and the genetic algorithm.

15. A computer program product comprising a computer readable medium having instructions recorded thereon, the instructions when executed by a computer implementing the method of any of the above claims.
