Title: HOSE CLAMP WITH RIPPLED SPRING LINER

Abstract: An improved hose clamp having an annular band having an inner face, tensioning means, and an annular spring liner; the spring liner having a circumferential shoulder near an edge of the liner; and a central, cylindrical, rippled, contact portion of smaller circumference than the shoulder, and of smaller width than the inner face of the band. The shoulder is adapted to abut the inner face and the contact portion is adapted to contact a hose or other article to be clamped. The ripples may be symmetric, for example, sinusoidal, or asymmetric, such as saw-tooth shaped.
HOSE CLAMP WITH RIPPLED SPRING LINER

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims priority under 35 U.S.C. § 119 to U.S. Patent Application Serial No. 13/188,103 entitled "HOSE CLAMP WITH RIPPLED SPRING LINER," which was filed on July 21, 2011, the entirety of which is incorporated herein by reference.

FIELD OF THE INVENTION

This invention relates generally to the field of hose clamp assemblies, more particularly to a spring liner that is associated with a hose clamp assembly, and specifically to a spring liner with a central, rippled, hose-contact portion.

DESCRIPTION OF THE PRIOR ART

Hose clamps are commonly utilized to join together hoses and fittings or connectors (referred to hereinafter as fittings), for example, within the automotive industry. Hose clamps, hose and fittings respond to changes in ambient temperature and system temperatures based on the thermal properties of the aforementioned components. Differing coefficients of thermal expansion of these components can result in thermally-induced reductions in clamping force, thus creating the potential for fluid or gas leakage. In addition, changes in elasticity of the hose materials over time due to creep, compression set, or deterioration can also reduce the clamping force and create the potential for fluid leakage.

Various types of spring liners used in conjunction with hose clamps are known. U.S. Pat. Nos. 7,178,204 and 7,302,741 are exemplary of the art, disclosing a spring liner having two inward projecting ridges with an outward-projecting ridge in between. The ridges create two zones of very high compression in the hose, while the central ridge area creates a zone of lesser compression.

Mention is also made of a co-pending application by the same applicant titled "Hose Clamp With Flat Spring Liner," U.S. Application Serial No. 13/188,093, which was filed on July 21, 2011, the contents of which are hereby incorporated herein by reference.
SUMMARY

It is an aspect of the present invention to provide an improved spring liner which allows a hose clamp to self-compensate for changes in elastic properties and diametric changes of the underlying hose and fittings. The invention is directed to an annular spring liner for a hose clamp having a circumferential shoulder near each edge of the liner and a central inwardly-directed circumferential, cylindrical ridge with rippled contact portion there between the two shoulders. The hose clamp seats on the shoulders of the liner when the clamp is tensioned. Thus, at least after assembly, and before tensioning of the hose clamp, the rippled central ridge is separated from the inner face of the tensioning band of the hose clamp by a gap of fairly uniform thickness. The width of the rippled contact portion is less than the width of the inner face of the tensioning band. The width of the rippled contact portion may be in the range from 40% to 75% of the width of the inner face of the tensioning band.

In another embodiment of the invention, the spring liner further has on at least a portion of one or both circumferential edges a radially outwardly-flared flange.

It is another aspect of the present invention to provide an improved hose clamp assembly having an annular band having an inner face, a tensioner disposed to facilitate constriction of the band, and the annular spring liner as described above.

The foregoing has outlined rather broadly the features and technical advantages of the present invention in order that the detailed description of the invention that follows may be better understood. Additional features and advantages of the invention will be described hereinafter which form the subject of the claims of the invention. It should be appreciated by those skilled in the art that the conception and specific embodiment disclosed may be readily utilized as a basis for modifying or designing other structures for carrying out the same purposes of the present invention. It should also be realized by those skilled in the art that such equivalent constructions do not depart from the spirit and scope of the invention as set forth in the appended claims. The novel features which are believed to be characteristic of the invention, both as to its organization and method of operation, together with further objects and advantages will be better understood from the following description when considered in connection with the accompanying figures. It is to be expressly understood, however, that each of the figures is provided for the purpose of illustration and description only and is not intended as a definition of the limits of the present invention.
BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in and form part of the specification in which like numerals designate like parts, illustrate embodiments of the present invention and together with the description, serve to explain the principles of the invention. In the drawings:

FIG. 1 is a perspective exploded view of a hose clamp assembly including clamp and spring liner in accordance with an embodiment of the present invention;

FIG. 2 is a partial sectional view of the spring liner of FIG. 1, taken along section 2-2;

FIG. 3 is a partially fragmented view of a hose clamp assembly including spring liner, hose, and fitting in accordance with an embodiment of the present invention; and

FIG. 4 is a partial sectional view of a spring liner according to another embodiment of the invention.

DETAILED DESCRIPTION

The present invention provides for a means of reducing the contact surface area of the inside diameter (ID) of traditional worm-gear hose clamp in order to increase the unit loading the hose clamp assembly imparts to the underlying hose or substrate, while increasing the grip of the hose clamp on the underlying hose. The reduction in contact surface area is achieved by the use of a circular liner that is inserted into the ID of a hose clamp or tensioning band 1. The cross-section of the liner has shoulders 5 with contact surfaces on their outside diameter (OD) which are together approximately equal in axial extent (width) to the inside surface width of the hose clamp or tensioning band. The edges of the shoulders may project upward towards the hose clamps or tensioning band at angles to hold the liner captive within the hose clamp or tensioning band ID. The profile of the liner also includes a rippled, but otherwise flat, cylindrical contact portion 7 positioned inward or lower than shoulders 5. By contact is meant that rippled portion 7 is intended to contact the underlying hose or substrate and increase the force required to force a clamp off of the hose, relative to a flat liner. This rippled contact surface is narrower than the hose clamp or tensioning band 1 width and may be in the range of 40% to 75% of the hose clamp or tensioning band width. Two legs 6 bridge between the two shoulders and the lower contact portion 7 of the liner. These legs may be
symmetrical and are located on either side of the lower contact surface and project outward at acute angles relative to the clamp centerline, thus reaching to and attaching to the upper shoulders.

The increase in unit loading can also be described as an increase in the radial pressure the clamp exerts on the underlying hose or substrate. The radial pressure (pr) a hose clamp or a tensioned band exerts is a function of the band tension (T), the band width (w) and the clamping diameter (d). For any fixed value of "T" and "d", an increase in "w" will decrease radial pressure, and a decrease in "w" will increase radial pressure. Manipulation of a simplified hoop stress formula can demonstrate this behavior; 2T = p_r w d transposes to p_r = 2T/(w d).

In addition to increasing a hose clamp or tension bands' radial pressure as a result of the liner's narrower contact width, the liner also can act as a spring, thus providing a thermal-compensating feature for the clamp. The spring effect will be described in more detail later. First, the drawings will be discussed in more detail.

Referring to FIG. 1, a hose clamp is shown comprising an outer annular band 1, and a typical tensioning means 3, 4. FIG. 1 also shows in exploded view rippled spring liner 9 in accordance with the present invention. In other embodiments, spring liner 19 is shown in section in FIGS. 2-3 and spring liner 29 in FIG. 4. Spring liner 9, as well as spring liners 19 and 29, is an annular ring with overlapping ends 10. Spring liner 9, 19 and 29 comprise two flat annular circumferential shoulders 5 near the edges of the liner, a rippled central annular circumferential contact portion 7 located between two shoulders 5 and of smaller circumference than the shoulders, and two annular circumferential legs 6 there between connecting the edges of shoulders 5 to the edges of rippled contact portion 7. FIGS. 2 and 4 show radial height differential A between the two shoulders 5 and the rippled contact portion 7. When liner 9, 19, or 29 is inserted into clamp band 1, the inner face of band 1 will abut or seat on shoulders 5, and gap A will result between the outer surface of contact portion 7 and the inner face of band 1 in the absence of clamp tensioning forces. Thus, rippled contact portion 7 does not abut the inner face of band 1 in the absence of clamp tensioning forces. The gap, A, is fairly uniform, but for the ripples. In other words, the central part of the liner is substantially flat, but with the addition of the small ripples. The ripples are a series of corrugations or small waves that are smaller in amplitude than the gap, A, and also smaller in wavelength that the width of the band or the contact portion 7. Preferably there are at least three ripples in the rippled portion, or four or
more. The ripples appear in cross sections of the liner, i.e. radial sections in a plane parallel to and passing through the center axis of the clamp.

The terms outward and inward refer to direction with respect to the center axis of the generally circular liner. Inward or inner generally means directed toward the center axis of the liner. Outward or outer generally means directed away from the center axis of the liner.

Upon applying clamp tensioning forces, i.e., tightening or tensioning of the band, the overlap section 10 of the liner can increase in length, resulting in a decrease in the circumference of the liner. As the band tightens, the liner is thus pulled into compressive engagement with the associated hose. FIG. 3 illustrates the hose clamp assembly in use with a hose 11 and a hose fitting 12. Band 1 of the hose clamp seats on the two shoulders 5. The inward facing rippled contact portion 7 of the liner creates a zone of relatively uniform compression 14 in the hose. Ripples 17 in the embodiment of FIG. 2 are of generally sinusoidal shape. The ripples will push into the hose surface, increasing the force required to pull the clamp off the hose. Other symmetric ripple profiles may be advantageously used, such as triangular, trapezoidal, or generally curvilinear.

The ripples also are believed to reduce leakage and/or increase the pressure required to produce leakage under the clamp. This effect may be the result of an increased tortuosity for any gas or liquid molecule trying to diffuse or permeate out in the region of the ripples.

FIG. 4 shows another embodiment in which ripples 27 are of asymmetric shape, namely saw tooth or triangular shape. An advantage of asymmetric, saw tooth ripples is that the pull-off force is direction-dependent and therefore the liner can be oriented to maximize the resistance to being pulled off in a desired direction. Saw tooth ripples 27 in FIG. 4 may be characterized by the two tooth angles, α and β. In FIG. 4, α and β are defined with respect to a vertical line. The angle, α, may be set as desired, for example, in the range of from zero to 50°, or from 50° to 400°, or from 5° to about 25°, or about 10°. The angle, β, may be set as desired, for example, in the range of from 20° to 90°, or from 30° to 80°, or from 35° to about 60°, or about 40°.

The profile of the liner is designed so that the two legs 6 can deflect under the compressive forces, creating a spring effect. As the band is tensioned, the deflection of the legs will cause gap A to decrease to A' (A'<A), or perhaps even disappear completely. As the band is tensioned, the deflection may also cause the rippled contact surface to deform slightly. The
decrease in gap is an indication of the amount of spring energy stored in the annular spring liner. The net effect of these radial and axial deflections and the resulting compression forces on the hose is a much better initial and long term sealing effect than obtained with prior art hose clamp liner designs.

As the hose and clamp assembly is exposed to thermal fluctuations, the spring liner can respond by further deflecting or by relaxing, thus helping to maintain an excellent sealing force on the hose assembly. As the hose material, which is typically vulcanized rubber, takes on a compression set, or inelastic deformation, due to deterioration of elastic properties over time, the force exerted by the rubber will relax or decline, and the spring liner again relaxes or releases some of the stored spring energy, thus maintaining an excellent sealing force on the hose. Compared to prior liner designs with narrow ridges which create zones of very high compression, the present invention creates a more uniform zone of moderate compression, which may advantageously avoid extreme deformations and extreme effects of compression set in the rubber hose being clamped, while still providing a high degree of mechanical grip on the hose.

If the hose clamp is tensioned to the extent that gap A' is eliminated and the outer surface of contact portion 7 contacts the inner surface of band 1, then any further deflection of the spring liner requires much higher forces, commensurate with a dramatic increase in spring rate. Under this condition, the deflection of the spring liner in response to thermal expansion of the hose is very limited. However, under this condition, the spring liner's ability to relax or respond to thermal contraction of the hose is maximized. Thus, the clamp and spring liner may be designed so that in use, gap A' is maintained even in the presence of clamp tensioning forces. Alternately, the clamp and spring liner may be designed so that in use, the outer surface of the rippled contact portion 7 may abut the inner face of the hose clamp in the presence of clamp tensioning forces.

As shown in FIGS. 2 to 4, spring liner 19 may also have one or two radially outward flared flanges 8 to aid in aligning liner 19 within band 1. The flanges shown in the figures flare outward at about a 45° angle. Any suitable flare angle or flare shape may be used. Flanges 8, as well as legs 6, may be sharply bent or may have a more rounded, gradual transition from the adjoining shoulders 5 or contact portion 7. Flanges 8 may extend the entire circumference of the liner or may be cut short in appropriate places to reduce interference in the overlap section 10 of the liner or to reduce interference between the liner and the tensioning means 3, 4. Alternately, or in addition to a flange, the spring liner may be more or less
permanently affixed to band I by any means that provides an adequate bond, such as, but not limited to, heat welding, chemical welding, chemical bonding, staking, mechanical fasteners, or a combination of two or more of the foregoing.

The spring force exerted by the liner depends on the thickness and modulus of the material of which it is constructed. The force also depends on the precise profile, i.e. the shape and size of the legs, contact portion, and shoulders. The profile shown in FIG. 2, when formed out of sheet metal about 0.012 inches (0.3 mm) thick, is suitable for typical automotive hose clamping applications. One skilled in the art would be able to alter the materials, material properties, shoulder and rippled surface dimensions, flange angles, overlap distance, and/or spring liner thickness to optimize the rippled spring liner for particular applications. The profile need not be perfectly symmetric. The two shoulders, the legs, and the central rippled surface may all be of different sizes. The central rippled surface need not be at the exact center of the annular liner. The two leg angles may be different. The thickness of the liner may also vary in the axial direction. One or more of the shoulders and/or one or more of the legs may also be rippled.

The shoulders need not be broad, flat structures. A shoulder or shoulders may be a circumferential line of contact adapted to abut the inner face of the band of the hose clamp. Such a shoulder could be an outwardly convex ridge formed near the edge of the liner, or it could simply be an edge of the liner. The important feature of the shoulder is that it be adapted to contact or abut the inner face of the band of the hose clamp. Viewed in section as in FIG. 3, the contact between the inner face of band I and shoulder 5 could therefore be a point or a line. In three dimensional terms, the contact between the inner face of band I and shoulder 5 could therefore be a circular line or a cylindrical area, depending on the shape of the shoulder.

Friction between the overlapping ends of the spring liner can affect the clamping force achieved during assembly. To reduce the friction force, the overlapping ends may be coated with wax or other suitable lubricant. To increase the friction force, the overlapping section may be cleaned, roughened, grooved, knurled, or the like. Thus, one skilled in the art can optimize the friction as needed or desired.

Any of the various hose clamp tightening or tensioning means, i.e., "tensioner," known in the art may be used. By way of illustration, the tensioning mechanism may be a worm drive 3, 4 as shown in FIG. 1. Alternatively, the tensioner may be a T-bolt, a ratcheting mechanism, a bolt and barrel mechanism, a nut and bolt assembly, a permanent crimp, or the like, or combinations thereof. Alternatively, the clamp may be an endless band with thermally
frozen-in strain, which is tensioned by releasing the strain and allowing the band to shrink onto the spring liner, hose and fitting. In addition, tensioning band or hose clamp width may vary. The proportionality of tensioning band width to liner width and liner contact width may vary.

Other known features of hose clamps may be incorporated if desired without departing from the scope of the invention. For example, various means of attaching the assembly to the hose, such as adhesive, a vulcanizing patch, a locating tab, a locating clip, and the like may be incorporated. Cutouts or apertures for adjusting spring stiffness, or the like may be incorporated.

In actual practice, a hose clamp with an annular spring liner is placed over the hose and fitting to be joined. Clamp diameter is reduced by means of the tensioning mechanism. Spring liner diameter is reduced proportionally to the clamp diameter reduction by increasing the circumferential overlap length of the liner. As the combined hose clamp and annular spring liner diameters decrease, radial pressure acting on the underlying hose and fitting increase. Because of the shape of the liner, the radial pressure on the hose is amplified from that generated by the clamp alone, while remaining relatively uniform in the hose region under the liner.

As the radial forces acting on the spring liner increase as a result of increased tension in the outer band, the spring liner deflects in such a manner that shoulders 5 deflect downward towards hose 11. This movement can continue until the desired tension is achieved. However, the movement becomes limited at the point where the central rippled portion 7 contacts (if ever) the inner face of the clamp band 1. The deflections are elastic, spring-like behavior. Therefore, the liner can respond to variations in band tension and/or radial pressures as a spring. This spring behavior insures that the central rippled portion 7 exerts sufficient radial pressure on the hose throughout the life of the clamp installation.

As an example of a possible modification, it is envisioned that in one embodiment of the invention, the inner face of the hose clamp could initially when assembled contact one shoulder of the spring liner, there being a gap between the inner face of the clamp and a second shoulder of the liner. As the hose clamp of this embodiment is tensioned, the gap between the inner face and the second shoulder would close as deformation energy is stored in the spring liner, with the clamp perhaps even finally seating on the second shoulder.

The use of an embodiment of the invention has benefits. As mentioned previously, the force required to pull off the clamp may be increased, resulting in higher working pressure and better sealing. Also, the clamp pressure is amplified relative to a band
without a liner at a given tension. The generally flat central portion of the liner with only relatively small ripples results in a more uniform pressure distribution both around the hose and along the hose than for the prior art spring liner having two inward ridges according to U.S. Pat. No. 7,302,741. This could be helpful for certain applications or embodiments.

Edge effects and relaxation or compression set effects within the rubber, may make the results or advantages to be dependent on the details of the hose construction and materials which is being clamped. Thus, the benefits of the invention, and the comparative advantages relative to the prior art liner, may depend on the type of hose and the type of application. The prior art liner, with its two larger ridges could still give higher peak pressures immediately under the ridges. However, some types of hose or application may be better clamped with a higher average pressure, but lower peak pressure.

Although the present invention and its advantages have been described in detail, it should be understood that various changes, substitutions, and alterations can be made herein without departing from the spirit and scope of the invention as defined by the appended claims.

Moreover, the scope of the present application is not intended to be limited to the particular embodiments of the process, machine, manufacture, composition of matter, means, methods, and steps described in the specification. As one of ordinary skill in the art will readily appreciate from the disclosure of the present invention, processes, machines, manufacture, compositions of matter, means, methods, or steps, presently existing or later to be developed that perform substantially the same function or achieve substantially the same result as the corresponding embodiments described herein may be utilized according to the present invention. Accordingly, the appended claims are intended to include within their scope such processes, machines, manufacture, compositions of matter, means, methods, or steps. The invention disclosed herein may suitably be practiced in the absence of any element that is not specifically disclosed herein.
WHAT IS CLAIMED IS:

1. An annular spring liner, for a hose clamp having an inner face, comprising: a circumferential shoulder near an edge of said liner; and a central, cylindrical, rippled, contact portion of smaller circumference than said shoulder; wherein said shoulder is adapted to abut said inner face.

2. The spring liner of claim 1 further comprising a circumferential shoulder near each edge of said liner, wherein both said shoulders abut said inner face.

3. The spring liner of claim 2 wherein said rippled contact portion does not abut said inner face in the absence of clamp tensioning forces.

4. The spring liner of claim 3 wherein said rippled contact portion is narrower than said inner face.

5. The spring liner of claim 4 wherein said rippled contact portion has a width in the range of 40% to 70% of the width of said inner face.

6. The spring liner of claim 4, further comprising on at least one edge a radially outwardly flared flange.

7. The spring liner of claim 3, further comprising on each circumferential edge a radially outwardly flared flange extending beyond the width of the inner face.

8. The spring liner of claim 1 wherein said liner has generally circular shape with overlapping ends.

9. The spring liner of claim 1 wherein said rippled portion comprises ripples of generally sinusoidal shape.
10. The spring liner of claim 1 wherein said rippled portion comprises ripples of saw-tooth shape.

11. A hose clamp having an inner face and an annular spring liner, said liner comprising:
   a circumferential shoulder near an edge of said liner; and
   a central, cylindrical, rippled, contact portion of smaller circumference than said shoulder;
   wherein said shoulder is adapted to abut said inner face.

12. The hose clamp of claim 11 further comprising a circumferential shoulder near each edge of said liner, wherein both said shoulders abut said inner face.

13. The hose clamp of claim 12 wherein said rippled contact portion does not abut said inner face in the absence of clamp tensioning forces and a gap is defined there between.

14. The hose clamp of claim 13 wherein said rippled contact portion is narrower than said inner face.

15. The hose clamp of claim 14 wherein said rippled contact portion has a width in the range of 40% to 70% of the width of said inner face.

16. The hose clamp of claim 14, further comprising on at least one edge a radially outwardly flared flange.

17. The hose clamp of claim 13, further comprising on each circumferential edge a radially outwardly flared flange extending beyond the width of the inner face.

18. The hose clamp of claim 10 wherein said liner has generally circular shape with overlapping ends.
19. The hose clamp of claim 10 wherein said rippled portion of said spring liner comprises ripples of generally sinusoidal shape.

20. The hose clamp of claim 1 wherein said rippled portion of said spring liner comprises ripples of saw-tooth shape.

21. The hose clamp of claim 13 further comprising a tensioner.

22. The hose clamp of claim 21 wherein said tensioner comprises a worm drive.
