DESCRIPTION

Description

TECHNICAL FIELD

[0001] The invention relates to methods for treating a human subject who has X-linked Retinitis Pigmentosa (XLRP) or another ophthalmological condition due to a loss-of-function mutation in the gene encoding the retinitis pigmentosa GTPase regulator (RPGR) protein, the method comprising administering to the subject a nucleic acid comprising an adeno-associated viral vector comprising an abbreviated human RPGR cDNA.

BACKGROUND

[0002] Retinitis pigmentosa (RP) is a leading form of inherited blindness in humans. Of the three general modes of inheritance (autosomal dominant, autosomal recessive, and X-linked), X-linked RP (XLRP) is associated with a severe form of disease involving both rod and cone photoreceptors as primary targets (Berson 1993; Sandberg and others 2007). Over 70% of X-linked RP and 10% - 20% of all RP cases are caused by mutations in the gene encoding RPGR (Bader and others 2003; Branham and others 2012; Churchill and others; Pelletier and others 2007). Given that mutations in well over 100 genes are currently known to cause RP and the greater severity of X-linked disease, RPGR is one of the most important RP disease genes.

[0003] WO2014011210 describes methods of ameliorating vision loss and other conditions associated with retinitis pigmentosa and x-linked retinitis pigmentosa in a subject.

[0004] WO0177380 describes methods for diagnosing a disease or a predisposition to disease by genotyping a RPGR gene from an individual and identifying the presence of one or more disease causing mutation(s).

[0005] WO0138578 describes methods for identifying dogs which have X-linked progressive retinal atrophy (XLPR) by testing a biological sample with genetic markers which co-segregate with a XLPR gene locus.

[0006] Pawlyk *et al.* (2016) describes photoreceptor rescue by an abbreviated human RPGR gene in a murine model of X-linked retinitis pigmentosa.

[0007] Hong *et al.* (2000) describes a single abbreviated RPGR-ORF15 variant reconstitutes

RPGR function *in vivo*.

[0008] Human retinitis pigmentosa GTPase regulator (RPGR)-ORF15 gene (SEQ ID: 5) is given in Geneseq Accession No. BCK76671.

[0009] Human retinitis pigmentosa GTPase regulator (RPGR)-ORF15 protein (SEQ: 6) is given in Geneseq, Accession No. BCK76672.

SUMMARY

[0010] The present invention is based on the discovery of an abbreviated form of human RPGR that successfully recreates functional RPGR activity, and thus includes nucleic acids for use in methods for treating subjects who have RP caused by mutations in RPGR. Subjects who can be treated include those who have loss of visual function (e.g., impaired response on electroretinographic (ERG) testing), but retain some photoreceptor cells as determined by optical coherence tomography (OCT).

[0011] The invention is defined by the claims. In particular, the invention provides a nucleic acid encoding an abbreviated human RPGR protein, wherein the abbreviated human RPGR protein is at least 95% identical to the full length of SEQ ID NO:2.

[0012] Also provided is:

a viral vector comprising the nucleic acid of the invention;

an isolated host cell comprising the viral vector of the invention;

a nucleic acid of the invention, for use in treating a human subject who has X-linked Retinitis Pigmentosa (XLRP) or another ophthalmological condition due to a loss-of-function mutation in the gene encoding the retinitis pigmentosa GTPase regulator (RPGR) protein;

a viral vector of the invention, for use in treating a human subject who has X-linked Retinitis Pigmentosa (XLRP) or another ophthalmological condition due to a loss-of-function mutation in the gene encoding the retinitis pigmentosa GTPase regulator (RPGR) protein; and

an adeno-associated viral vector comprising a nucleic acid encoding an abbreviated human RPGR protein, wherein the abbreviated human RPGR protein is at least 95% identical to the full length of SEQ ID NO:2, for use in treating a human subject who has X-linked Retinitis Pigmentosa (XLRP) or another ophthalmological condition due to a loss-of-function mutation in the gene encoding the retinitis pigmentosa GTPase regulator (RPGR) protein.

Aspects of the disclosure

[0013] Also disclosed are methods for treating a human subject who has XLRP or another clinically-defined ophthalmological condition due to a loss-of-function mutation in the gene encoding the retinitis pigmentosa GTPase regulator (RPGR) protein. The methods include administering to the subject a nucleic acid comprising an adeno-associated viral vector comprising an abbreviated human RPGR cDNA, wherein the abbreviated human RPGR cDNA encodes a protein that is at least 80% identical to the full length of SEQ ID NO:2, optionally with a deletion of up to a total of 200 additional amino acids in the region surrounding the deleted region in SEQ ID NO:2 (i.e., between amino acids 861 and 862 of SEQ ID NO:2).

[0014] In some aspect, the RPGR cDNA is under the control of a human rhodopsin kinase (hRK) promoter, e.g., an hRK promoter that comprises or consists essentially SEQ ID NO:5.

[0015] In some aspects, the adeno-associated viral vector is AAV-2, serotype-8 (AAV2/8) or AAV-8.

[0016] In some aspects, the RPGR cDNA comprises or consists essentially of a sequence that is at least 80% identical to SEQ ID NO: 1.

[0017] In some aspects, the human RPGR cDNA encodes a protein that is at least 95% identical to the full length of SEQ ID NO:2.

[0018] In some aspect, the methods include administering the nucleic acid in a low dose of about 2×10^{10} vg/mL, a middle dose of about 2×10^{11} vg/mL, or a high dose of about 2×10^{12} vg/mL. In some aspect, the nucleic acid is administered into the subretinal space. In some aspect, a micro injection cannula is inserted into the subretinal space, temporal to the optic nerve and just above the major arcade vessels, so that fluid flow can be directed towards the macula.

[0019] In another aspect, the nucleic acids encoding an abbreviated human RPGR are described, wherein the abbreviated human RPGR cDNA encodes a protein that is at least 80% identical to the full length of SEQ ID NO:2, optionally with a deletion of up to 200 additional amino acids surrounding the deleted region of SEQ ID NO:2.

[0020] In some aspect, the RPGR cDNA is under the control of a human rhodopsin kinase (hRK) promoter, e.g., an hRK promoter that comprises or consists essentially SEQ ID NO:5.

[0021] In some aspect, the RPGR cDNA comprises or consists essentially of a sequence that is at least 80% identical to SEQ ID NO: 1.

[0022] In some aspect, the human RPGR cDNA encodes a protein that is at least 95% identical to the full length of SEQ ID NO:2.

[0023] In some aspect, the human RPGR cDNA is at least 80% identical to the full length of SEQ ID NO:1, optionally with a deletion of nucleotides encoding up to 200 additional amino acids surrounding the deleted region.

[0024] Also provided herein are vectors, e.g., adeno-associated viral vectors, e.g., AAV-2, serotype-8 (AAV2/8) or AAV-8, comprising the nucleic acids encoding an abbreviated human RPGR as described herein, as well as isolated cells (i.e., cells that are not present in a living human subject or host animal) that harbor the nucleic acids encoding an abbreviated human RPGR and optionally express the abbreviated human RPGR protein.

[0025] Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Methods and materials are described herein for use in the present invention; other, suitable methods and materials known in the art can also be used. The materials, methods, and examples are illustrative only and not intended to be limiting.

[0026] Other features and advantages of the invention will be apparent from the following detailed description and figures, and from the claims.

DESCRIPTION OF DRAWINGS

[0027]

Figures 1A-B. (A) Maps of the native human RPGR ORF15 coding region and both shortened forms of AAV-delivered human ORF15cDNA. (B) Immunoblots for the two recombinant forms of human *RPGR-ORF15*. AAV delivery of the small-deletion human cDNA (AAV-*ORF15-L*, "long form") leads to expression of a human RPGR-ORF15 protein of ~ 160 kD in size. AAV delivery of the large-deletion human cDNA (AAV-*ORF15-S*, "short form") leads to expression of a protein of ~130 kD in size. Both forms of human RPGR-ORF15 protein are smaller than endogenous human RPGR ORF15 found in human retinal tissue (~ 200 kD).

Figures 2A-D. RPGR ORF15 expression in *RPGR*^{-/-} mouse retinas following subretinal delivery of AAV-RPGR *ORF15*. (A) Fluorescence images of both the short (ORF15-S) and long (ORF15-L) forms of human RPGR ORF15 protein expression superimposed on Nomarski images to illustrate the layers of the outer retina. Staining of unfixed frozen retinal sections was performed at 3 weeks following treatment at 1-2 months of age. (B) Fluorescence images of both forms of human RPGR ORF15 co-localized with rootletin. Similar to WT, both forms of human RPGR ORF15 correctly localized to the photoreceptor connecting cilium just distal to rootletin. RPE, retinal pigment epithelium; OS, outer segment; CC (TZ), connecting cilium (transition zone); IS, inner segment; ONL, outer nuclear layer. (C) Ratio of hRPGR fluorescent particles to fluorescent rootletin fibers at the connecting cilium for *Rpgr*^{-/-} eyes (n=3) treated with ORF15-S, *Rpgr*^{-/-} eyes (n=3) treated with ORF15-L, and wt eyes (n=3). Counts were obtained for both rootletin within the inner segment and RPGR just distal to rootletin over a

100µm length of midperipheral retina. Values are means \pm 1 standard error. (D) Expression pattern of short and long form ORF15 protein in fixed floating retinal sections of *Rpgr*^{-/-} mice. Sections were stained for human RPGR ORF 15 protein localization 4-6 weeks following treatment at 2-3 months of age. In wt retina, murine RPGR ORF15 protein was seen as a discrete green fluorescent signal (dots) occupying the region between the photoreceptor inner and outer segments, at the level of the transition zone or connecting cilium. In contrast, the fluorescent signal for the short form of ORF15 (AAV-ORF15-S) is not limited to level of the photoreceptor connecting cilium but is also seen as diffuse signal throughout the inner and outer segments as well. The fluorescent signal for the long form of ORF15 shows very little, if any mislocalization, and is largely limited to the connecting cilium region similar to wt. OS, outer segment; CC (TZ), connecting cilium (transition zone); IS, inner segment; ONL, outer nuclear layer.

Figure 3. Immunohistochemical (yellow in original) analyses of rod and cone photoreceptors in treated (short and long form of ORF15) and control *RPGR*^{-/-} mouse retinas at age 13 months (6-months post injection). In the *RPGR*^{-/-} mouse retina treated with the short form of ORF15 (AAV8-ORF15-s), rhodopsin and cone opsin (mixed S & M cones in the inferior retina) mislocalization staining patterns are virtually indistinguishable from those seen in the control retina. Note the cone opsin mislocalization in the inner segments and synaptic layer in both of these mouse retinas. Similarly, rod and cone outer segments are shortened and disorganized with a reduced outer nuclear layer compared to an age matched wt retina. In contrast, in the *RPGR*^{-/-} mouse retina treated with the long form of ORF15 (AAV8-ORF15-l) rhodopsin shows outer segment partitioning similar to WT mouse retina. Also in the ORF15 long form treated retina rod outer segments are longer and well organized and the ONL is thicker compared with the control retina. Cone opsin staining shows more numerous cone photoreceptors with elongated and well-organized outer segments in the ORF 15 long form treated *RPGR*^{-/-} mouse retina compared with control.

Figures 4A-B. Rescue of photoreceptor cells following treatment with *RPGR* ORF15-l in *RPGR*^{-/-} mice. (A) Shown are stacked bar graphs for ONL thickness (top) and IS/OS length (bottom) for treated (red in original) and fellow control (blue in original) eyes in 3 mice at 18 months of age. (B) Representative light micrographs from a WT mouse and an ORF15-l treated and fellow control eye from an *RPGR*^{-/-} mouse at 18 months of age. Images were taken from the mid periphery along the vertical meridian in the superior retina,

Figures 5A-C. (A) Rod a-wave, rod b-wave, and cone b-wave amplitudes from 16 *RPGR*^{-/-} mice at 11-14 months of age. Control eyes (OD) showed disproportionate loss of cone b-wave amplitude relative to rod b-wave amplitude compared with the lower limits for wild-type mice. Except in one instance, treated eyes (OS) all had larger responses than fellow control eyes. In particular, note that more than half of the treated eyes at this age had rod ERG b-wave amplitudes that were at or above the lower limit of wild-type. Mean values for all three measures were significantly different between eyes ($P < 0.01$). (B) Scatterplots of ERG amplitude for 22 *RPGR*^{-/-} mice between 9 and 18 months of age on a log scale for the dark-adapted (rod) b-wave (upper graph) and light-adapted (cone) b-wave (lower graph). Data points have been shifted slightly horizontally for each age group to minimize data overlap. The

regression lines for treated and control eyes were fitted by repeated measures longitudinal regression using PROC MIXED of SAS based on all available data. (C) Representative Dark-adapted (DA) and Light-adapted (LA) ERG waveforms from a pair of ORF15-I treated and fellow control RPGR^{-/-} eyes at 18 months of age. WT (age-matched) ERG waveforms are shown for comparison. The control eye has severely reduced or nearly extinguished rod and cone ERGs, respectively, at this age. The treated eye, however, still has substantial rod and cone function at this time point that are approximately 70% and 35% of WT values, respectively.

Figure 6. Full-field ERGs to 0.5 Hz flashes of white light and to 30 Hz flashes of the same white light from 5 patients with XLRP due to RPGR ORF 15 mutations. Three or more traces are superimposed to illustrate reproducibility. Dots above traces designate flash onset. While the responses to 0.5 Hz responses were reduced by only 6% to 65% below the lower limit of normal (350 μ V), the responses to 30 Hz flashes were nondetectable as illustrated (i.e., without bandpass filtering and signal averaging).

DETAILED DESCRIPTION

[0028] Viral vector-mediated somatic gene therapy has shown great promise in treating animal models of human retinal degenerative disease. To date, there have been a number of successful studies using adeno-associated virus (AAV)-mediated gene delivery to rescue photoreceptor degeneration in small animal models (Ali and others 2000; Pang and others 2012; Pawlyk and others 2010; Pawlyk and others 2005; Tan and others 2009) and large animal models (Acland and others 2001; Alexander and others 2007; Beltran and others 2012; Komaromy and others 2010; Lheriteau and others 2009). In these cases, the retinal pigment epithelium (RPE) or photoreceptors have been the primary targets for transgene expression. In addition, phase I clinical trials involving gene therapy for patients with Leber Congenital Amaurosis (LCA) targeting the RPE (Bainbridge and others 2008; Cideciyan and others 2008; Maguire and others 2008) and more recently choroideremia (Maclaren and others 2014), have already met with some success. There are currently no clinical trials using AAV-mediated gene replacement therapy for the treatment of patients with X-linked RP.

[0029] The present inventors have previously demonstrated functional and morphological rescue of both rod and cone photoreceptor cells in mice lacking RPGR using an abbreviated murine RPGR ORF15 isoform lacking about 600 bp in the purine-rich carboxyl terminus using a transgenic approach (Hong and others 2005). Some variation in the length of the repetitive region is frequently found in normal individuals (Bader and others 2003; Jacobi and others 2005; Karra and others 2006). However, the function of an abbreviated human RPGR has not been described.

[0030] In the present study, a shortened human *RPGR ORF15* replacement gene, driven by a

previously described rhodopsin kinase (RK) promoter (Khani and others 2007; Sun and others 2010) and delivered in the fast acting AAV8 vector (Allocca and others 2007; Natkunarajah and others 2008), was able to rescue the photoreceptor degeneration phenotype in the *RPGR* knockout mouse model. The purine-rich repetitive region of ORF 15 exon is required for correct subcellular localization and function of RPGR, but that shortening of its length by up to one third appears not to compromise its function. This shortened RPGR replacement gene offers a viable alternative to the so far evasive "full-length" *RPGR ORF15* in future human gene therapy trials.

RPGR

[0031] *RPGR* is expressed in a complex pattern, with both default and ORF 15 variants having been described (Vervoort and others 2000). The default or constitutive form of *RPGR* spans exons 1-19 and ORF 15 terminates in a large alternative exon designated ORF 15 before the onset of exons 16-19. The ORF15 exon is unique in that it contains a long stretch of purine rich repetitive sequence that proved difficult to clone into cDNA and unstable in many procedures of recombinant DNA manipulations. While the smaller default form of *RPGR* is the predominant form in tissues with motile cilia (Hong et al., 2003) and many types of primary cilia (our unpublished data), the ORF15 isoform of *RPGR* is necessary for normal rod and cone function in the retina (Vervoort and others 2000; Vervoort and Wright 2002) and is expressed primarily in photoreceptors (Hong and others 2003). ORF15 is also a common site for mutations in *RPGR*, with mutations identified in 22-60% of patients with X-linked RP (Breuer and others 2002; Vervoort and others 2000).

[0032] The present inventors contributed to the development of the first mouse model of X-linked RP carrying a null mutation in *RPGR* with no detectable levels of any isoforms of *RPGR* (Hong and others 2000). *RPGR null* mice manifest a slowly progressive retinal degeneration that is characterized by early cone opsin mislocalization in cell bodies and synapses and reduced levels of rhodopsin in rods. As a result, these mice have a cone-rod degeneration. By 12 months of age significant photoreceptor cell loss and decline in cone and rod function, as measured by electroretinograms (ERG), become apparent. In the retina, *RPGR* is bound to the photoreceptor connecting cilium located in between the inner and outer segments via an *RPGR* interacting protein (RPGRIP1) (see, e.g., Boylan and Wright 2000; Hong and others 2001; Roepman and others 2000). The connecting cilium is analogous to the transition zone of motile or primary cilia that may serve as a gateway to the outer segment. This subcellular localization pattern and the mutant mouse phenotype suggest that *RPGR* may have a role in protein trafficking between the inner and outer segment of both rods and cones (Hong and Li 2002; Hong and others 2000; Hong and others 2001). In attempts to develop an *RPGR* mutant mouse model with a faster course of degeneration, several other *RPGR* mouse lines have been recently developed (Brunner, et al, 2010; Huang et al, 2012). There has also been a recent report of a naturally occurring model (rd9) of X-linked *RPGR* (Thompson and others 2012). In all of these cases, including the *RPGR null* mice display a slowly progressive loss photoreceptors but with varying degree of rod and cone involvement which may be due, in

part, to differences in strain and/or pigmentation. These findings indicate that the slow rate of degeneration in the knockout model is due to species differences rather than the ablation being incomplete, and confirm the applicability of this murine model in therapeutic studies of null *RPGR* mutations in patients.

[0033] Two variants (A and C) of the full-length human RPGR (also known as CRD; RP3; COD1; PCDX; RP15; XLRP3; orf15; and CORDX1) are described in GenBank; Isoform A is at Accession No. NM_000328.2 (nucleic acid) and NP_000319.1 (protein); Isoform C is at Accession No. NM_001034853.1 (nucleic acid) and NP_001030025.1 (protein). Variant (A) uses an alternate splice site and contains multiple alternative exons in the 3' coding region, compared to variant C, and encodes isoform A (also referred to as isoform 1) that is shorter and has a distinct C-terminus, compared to isoform C. The sequence used in the exemplary compositions described herein is set forth below as SEQ ID NO: 1. The sequences of human RPGR useful in the compositions and methods described herein can be at least 80%, e.g., 85%, 90%, 95%, or 100% identical to the full length of SEQ ID NO:1, with up to an additional 50, 100, 150, or 200 amino acids deleted from the deleted region, indicated by dashes in the sequence below.

Abbreviated form of Human RPGRORF15 sequence with 378bp deleted, and deleted region shown by dashes ("-"); number of dashes does not correlate with size of deletion)

[0038] The comparison of sequences and determination of percent identity between two sequences can be accomplished using a mathematical algorithm. For example, the percent identity between two amino acid sequences can be determined using the Needleman and Wunsch ((1970) J. Mol. Biol. 48:444-453) algorithm which has been incorporated into the GAP program in the GCG software package (available on the world wide web at gcg.com), using the default parameters, e.g., a Blossum 62 scoring matrix with a gap penalty of 12, a gap extend penalty of 4, and a frameshift gap penalty of 5.

RK Promoter

[0039] In some embodiments of the methods described herein, a replacement gene construct is used in which an abbreviated human RPGR cDNA as described herein is placed under the control of a human rhodopsin kinase (hRK) promoter. In some embodiments, the RK promoter is approx. 200 bp in length (a short promoter derived from the rhodopsin kinase (RK) gene, which has been shown to drive cell-specific expression in rods and cones (Khani et al., 2007; Sun et al., 2010; Young et al., 2003)). An exemplary hRK promoter sequence is -112/+87 (Khani et al., 2007):

Viral Delivery Vector

[0040] The abbreviated human RPGR cDNA, as described above, is packaged into a delivery vector, e.g., an AAV8 or AAV2/8 vector.

[0041] Replacement genes (cDNA) can be administered in any effective carrier, e.g., any formulation or composition capable of effectively delivering the component gene to cells *in vivo*. Approaches include insertion of the gene into non-pathogenic, non-replicating viral vectors, including recombinant retroviruses, adenovirus, adeno-associated virus, lentivirus, and herpes simplex virus-1, or recombinant bacterial or eukaryotic plasmids. Viral vectors transfect cells directly; plasmid DNA can be delivered naked or with the help of, for example, cationic liposomes (lipofectamine) or derivatized (e.g., antibody conjugated), polylysine conjugates, gramicidin S, artificial viral envelopes or other such intracellular carriers, as well as direct injection of the gene construct or CaPO₄ precipitation carried out *in vivo*.

[0042] A preferred approach for *in vivo* introduction of nucleic acid into a cell is by use of a viral vector containing nucleic acid, e.g., a cDNA. Infection of cells with a viral vector has the advantage that a large proportion of the targeted cells can receive the nucleic acid. Additionally, molecules encoded within the viral vector, e.g., by a cDNA contained in the viral vector, are expressed efficiently in cells that have taken up viral vector nucleic acid.

[0043] Retrovirus vectors and adeno-associated virus vectors can be used as a recombinant gene delivery system for the transfer of exogenous genes *in vivo*, particularly into humans. These vectors provide efficient delivery of genes into cells, and the transferred nucleic acids are stably integrated into the chromosomal DNA of the host. The development of specialized cell lines (termed "packaging cells") which produce only replication-defective retroviruses has increased the utility of retroviruses for gene therapy, and defective retroviruses are characterized for use in gene transfer for gene therapy purposes (for a review see Miller, Blood 76:271 (1990)). A replication defective retrovirus can be packaged into virions, which can be used to infect a target cell through the use of a helper virus by standard techniques. Protocols for producing recombinant retroviruses and for infecting cells *in vitro* or *in vivo* with such viruses can be found in Ausubel, et al., eds., Current Protocols in Molecular Biology, Greene Publishing Associates, (1989), Sections 9.10-9.14, and other standard laboratory manuals. Examples of suitable retroviruses include pLJ, pZIP, pWE and pEM which are known to those skilled in the art. Examples of suitable packaging virus lines for preparing both ecotropic and amphotropic retroviral systems include ΨCrip, ΨCre, Ψ2 and ΨAm. Retroviruses have been used to introduce a variety of genes into many different cell types, including epithelial cells, *in vitro* and/or *in vivo* (see for example Eglitis, et al. (1985) Science 230:1395-

1398; Danos and Mulligan (1988) *Proc. Natl. Acad. Sci. USA* 85:6460-6464; Wilson et al. (1988) *Proc. Natl. Acad. Sci. USA* 85:3014-3018; Armentano et al. (1990) *Proc. Natl. Acad. Sci. USA* 87:6141-6145; Huber et al. (1991) *Proc. Natl. Acad. Sci. USA* 88:8039-8043; Ferry et al. (1991) *Proc. Natl. Acad. Sci. USA* 88:8377-8381; Chowdhury et al. (1991) *Science* 254:1802-1805; van Beusechem et al. (1992) *Proc. Natl. Acad. Sci. USA* 89:7640-7644; Kay et al. (1992) *Human Gene Therapy* 3:641-647; Dai et al. (1992) *Proc. Natl. Acad. Sci. USA* 89:10892-10895; Hwu et al. (1993) *J. Immunol.* 150:4104-4115; U.S. Patent No. 4,868,116; U.S. Patent No. 4,980,286; PCT Application WO 89/07136; PCT Application WO 89/02468; PCT Application WO 89/05345; and PCT Application WO 92/07573).

[0044] Another viral gene delivery system useful in the present methods utilizes adenovirus-derived vectors. The genome of an adenovirus can be manipulated, such that it encodes and expresses a gene product of interest but is inactivated in terms of its ability to replicate in a normal lytic viral life cycle. See, for example, Berkner et al., *BioTechniques* 6:616 (1988); Rosenfeld et al., *Science* 252:431-434 (1991); and Rosenfeld et al., *Cell* 68:143-155 (1992). Suitable adenoviral vectors derived from the adenovirus strain Ad type 5 dl324 or other strains of adenovirus (e.g., Ad2, Ad3, or Ad7 etc.) are known to those skilled in the art. Recombinant adenoviruses can be advantageous in certain circumstances, in that they are not capable of infecting non-dividing cells and can be used to infect a wide variety of cell types, including epithelial cells (Rosenfeld et al., (1992) *supra*). Furthermore, the virus particle is relatively stable and amenable to purification and concentration, and as above, can be modified so as to affect the spectrum of infectivity. Additionally, introduced adenoviral DNA (and foreign DNA contained therein) is not integrated into the genome of a host cell but remains episomal, thereby avoiding potential problems that can occur as a result of insertional mutagenesis *in situ*, where introduced DNA becomes integrated into the host genome (e.g., retroviral DNA). Moreover, the carrying capacity of the adenoviral genome for foreign DNA is large (up to 8 kilobases) relative to other gene delivery vectors (Berkner et al., *supra*; Haj-Ahmand and Graham, *J. Virol.* 57:267 (1986)).

[0045] Yet another viral vector system useful for delivery of nucleic acids is the adeno-associated virus (AAV). Adeno-associated virus is a naturally occurring defective virus that requires another virus, such as an adenovirus or a herpes virus, as a helper virus for efficient replication and a productive life cycle. (For a review see Muzyczka et al., *Curr. Topics in Micro. and Immunol.* 158:97-129 (1992). It is also one of the few viruses that may integrate its DNA into non-dividing cells, and exhibits a high frequency of stable integration (see for example Flotte et al., *Am. J. Respir. Cell. Mol. Biol.* 7:349-356 (1992); Samulski et al., *J. Virol.* 63:3822-3828 (1989); and McLaughlin et al., *J. Virol.* 62:1963-1973 (1989). Vectors containing as little as 300 base pairs of AAV can be packaged and can integrate. Space for exogenous DNA is limited to about 4.5 kb. An AAV vector such as that described in Tratschin et al., *Mol. Cell. Biol.* 5:3251-3260 (1985) can be used to introduce DNA into cells. A variety of nucleic acids have been introduced into different cell types using AAV vectors (see for example Hermonat et al., *Proc. Natl. Acad. Sci. USA* 81:6466-6470 (1984); Tratschin et al., *Mol. Cell. Biol.* 4:2072-2081 (1985); Wondisford et al., *Mol. Endocrinol.* 2:32-39 (1988); Tratschin et al., *J. Virol.* 51:611-619 (1984); and Flotte et al., *J. Biol. Chem.* 268:3781-3790 (1993)).

[0046] In preferred embodiments, the viral delivery vector is a recombinant AAV2/8 virus.

[0047] Prior to administration, the final product will undergo a series of ultrapurification steps to meet clinical grade criteria.

Subject Selection

[0048] Subjects who are candidates for the present methods of treatment include those who have a diagnosis of RP caused by mutations in the gene encoding RPGR. Subjects suffering from other ophthalmological clinically-defined conditions caused by mutations in the gene encoding RPGR, e.g., X-linked cone-rod dystrophy, can also be treated using the methods described herein. A diagnosis of XLRP or another ophthalmological condition caused by mutations in the gene encoding RPGR can be made using methods known in the art.

[0049] The methods described herein can include identifying a subject, e.g., a child, adolescent, or young adult subject, who has XLRP or another ophthalmological condition caused by mutations in the gene encoding RPGR, or who is suspected of having XLRP or another ophthalmological condition caused by mutations in the gene encoding RPGR (e.g., based on the presence of symptoms of the condition and no other obvious cause), and obtaining a sample comprising genomic DNA from the subject, detecting the presence of a mutation in RPGR using known molecular biological methods, and selecting a patient who has a mutation in RPGR that causes XLRP or another condition. Detecting a mutation in RPGR can include detecting a mutation in ORF15, e.g., as described in Sandberg et al., (2007). Invest Ophthalmol Vis Sci 48, 1298-304; Dror et al., Am J Hum Genet. Nov 2003; 73(5): 1131-1146.

[0050] Mutations in RPGR ORF15 include frameshift mutations, nonsense mutations, splice-site mutations, and missense mutations. Exemplary mutations include *ORF15Glu446 (1-bp-del)*, *ORF15Glu447 (2-bp-del)*, and *ORF15GLys521(1-bp-ins)*.

[0051] Detecting a mutation in RPGR can also include sequencing all or part of (e.g., the ORF 15 region) the RPGR gene in a subject, and comparing the sequence to a reference sequence (e.g., GenBank Accession No. NG_009553.1), to detect a mutation. Frameshift mutations, truncation mutations, mutations that alter a conserved amino acid, or mutations that affect a regulatory (e.g., promoter) region can be considered to be mutations that can cause XLRP or another ophthalmological condition as described herein; an alteration in function can be confirmed by expressing the mutant in vitro (e.g., in cultured cells) or in vivo (e.g., in a transgenic animal), and assaying, e.g., function or subcellular localization.

[0052] Patients with XLRP or another ophthalmological condition due to RPGR mutations that can be treated using a method described herein preferably retain some photoreceptors and visual function, e.g., as measured by standard visual function or field tests and/or Optical Coherence Tomography (OCT, e.g., Spectral Domain-OCT (SD-OCT)); see, e.g., Sandberg et

al., Invest Ophthalmol Vis Sci. 2007;48:1298-1304. The methods described herein can include identifying subjects who have been diagnosed with XLRP or another ophthalmological condition due to RPGR mutations, who have a confirmed mutation in RPGR that causes their condition, and testing their visual ability and detecting the presence of residual central photoreceptors. Subjects, e.g., child, adolescent, young adult, or adult subjects, who can be treated using the present methods will preferably have visual acuity of at least 20/200 (methods for determining visual acuity are well known in the art; see, e.g., Johnson, Deafness and Vision Disorders: Anatomy and Physiology, Assessment Procedures, Ocular Anomalies, and Educational Implications, Charles C. Thomas Publisher; 1999) Carlson, N; Kurtz, D.; Heath, D.; Hines, C. Clinical Procedures for Ocular Examination. Appleton & Lange; Norwalk, CT. 1990) and a detectable outer nuclear layer in the central fovea (e.g., at least 75%, 80%, 90%, 95%, or 99% of normal thickness).

EXAMPLES

[0053] The invention is further described in the following examples, which do not limit the scope of the invention described in the claims.

Materials and Methods

[0054] The following materials and methods were used in the Examples set forth below.

Animals

[0055] The generation and analysis of *RPGR*^{-/-} mice have been described previously (Hong and others 2000). The *RPGR*^{-/-} mice used in this study were bred from sibling mating among nullizygous *RPGR* males and homozygous (*RPGR*^{-/-}) females maintained in our institutional animal facility. WT mice used in the study were C57BL from Charles River Laboratory (Wilmington, MA). Mice were maintained under 12hr light/12hr dark lighting cycle. The studies were done in accordance with the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research, and approved by the IACUC of the Massachusetts Eye and Ear Infirmary.

Plasmid construction and production of recombinant AA V8

[0056] Human RPGR ORF 15 cDNA were amplified from human retinal cDNA by PCR using primers designed to encompass the entire RPGR ORF 15 isoform coding region. No full-length ORF15 cDNAs were obtained despite repeated attempts using a variety of methods, consistent with the experience of other investigators and that of our own (Hong and others 2005).

Instead, we obtained an abbreviated ORF 15 cDNA containing a large 314 codon (942 bp) in-frame deletion in the ORF15 exon (2,517-bp remaining) with the bulk of the purine rich repetitive region removed (codons 696-1010del, "short form") (Fig. 1A). A second ORF15 cDNA was constructed through recombinant DNA manipulation which contained a 126-codon (378 bp) in-frame deletion within the highly repetitive region of exon 15 (with 3,081-bp remaining in the ORF15 exon) (codons 862-988del,"long form"). These ORF15 cDNAs were sequenced to verify fidelity. To construct the AAV vectors, RPGR cDNAs were inserted into the multiple cloning site of the parental pAAV-RK-zsGreen vector. The resulting pAAV-RK-mRPGR and pAAV-RK-hRPGR vectors were packaged into AAV. AAV2/8 pseudotyped vector was generated by tripartite transfection: (1) AAV vector plasmid encoding the gene of interest, (2) AAV helper plasmid pLT-RC03 encoding AAV Rep proteins from serotype 2 and Cap proteins from serotype 8, and (3) adenovirus helper miniplasmid pHGTI-Adeno1) into 293A cells. The transfection was performed using a protocol developed by Xiao and co-workers (Xiao, et al., 1998). Two days after transfection, cells were lysed by repeated freeze and thaw cycles. After initial clearing of cell debris, the nucleic acid component of the virus producer cells was removed by Benzonase treatment. The recombinant AAV vector particles were purified by iodixanol density gradient. The purified vector particles were dialyzed extensively against PBS and tittered by dot blot hybridization.

Subretinal injections

[0057] Mice were placed under general anaesthesia with an intraperitoneal injection of ketamine (90 mg/kg)/xylazine (9 mg/kg). A 0.5% proparacaine solution was applied to the cornea as a topical anesthetic. Pupils were dilated with topical application of cyclopentolate and phenylephrine hydrochloride. Under an ophthalmic surgical microscope, a small incision was made through the cornea adjacent to the limbus using an 18-gauge needle. A 33-gauge blunt needle fitted to a Hamilton syringe was inserted through the incision behind the lens and pushed through the retina. All injections were made subretinally in a location within the nasal quadrant of the retina. Injections were made subretinally within the nasal quadrant of the retina. Each eye received either 2×10^9 vector genome (AAV- ORF15-L) or 5×10^9 vector genome (AAV- ORF15-S) in a 1 μ l volume. RPGR-ORF15 vectors were administered to the left eye (OS, oculus sinister) and control vector (AAV8-RK- EGFP) were administered to the right eye (OD, oculus dexter). These are referred throughout this text as "treated" or "control", respectively. Visualization during injection was aided by the addition of fluorescein (100mg/ml AK-FLUOR, Alcon, Inc.) to the vector suspensions at 0.1% by volume. Fundus examination following the injection found > 30% of the retina detached in most cases, confirming successful subretinal delivery. Cohorts of mice (n=50 total) were injected at 1 month of age for protein expression studies and at 3 to 7 months of age (since ERGs remained normal during this age period) for functional (ERG) and histological studies, prior to major photoreceptor loss.

Histology and immunofluorescence

[0058] For both light microscopy and transmission electron microscopy, enucleated eyes were fixed for 10 minutes in 1% formaldehyde, 2.5% glutaraldehyde in 0.1 M cacodylate buffer (pH7.5). Following removal of the anterior segments and lens, the eyecups were left in the same fixative at 4°C overnight. Eye cups were washed with buffer, post-fixed in osmium tetroxide, dehydrated through a graded alcohol series and embedded in Epon. Semi-thin sections (1 µm) were cut for light microscopy observations. For EM, ultrathin sections were stained in uranyl acetate and lead citrate before viewing on a JEOL 100CX electron microscope.

[0059] For immunofluorescence staining of ciliary proteins, eyes were enucleated, shock frozen, and sectioned at 10-µm thick in a cryostat. Unfixed frozen sections were then collected on glass and stained. For immunostaining of all other proteins, floating retinal sections were collected and stained. For this process eyes were placed in fixative (2% formaldehyde, 0.25% glutaraldehyde/PBS) and their anterior segments and lens were removed. Duration of fixation was typically 20 minutes. The fixed tissues were soaked in 30% sucrose/PBS for at least 2 hours, shock frozen and sectioned similar to unfixed tissues. Sections were then collected into PBS buffer and remained free floating for the duration of the immunostaining process. Stained sections were viewed and photographed on a laser scanning confocal microscope (model TCS SP2; Leica). Antibodies used were mouse RPGR (S1), human RPGR C100, anti-rootletin, 1D4 (anti-rhodopsin), mixed blue/green cone anti-opsin, and Hoechst 33342, nuclear dye stain.

Immunoblotting analysis

[0060] Retinal tissues were homogenized in RIPA buffer, boiled in Laemmli buffer and loaded at 15 µg/lane on 5% SDS-PAGE gels. After gel separation, proteins were blotted to PVDF membrane by electrotransfer. The membranes were blocked with 5% non-fat milk and incubated with primary antibodies overnight at room temperature. After washing, membranes were incubated with peroxidase-conjugated secondary antibodies. SuperSignal® West Pico Chemiluminescent Substrate (Pierce) was used for detection. For normalization, protein samples were separated on standard SDS-PAGE and probed with a transducin α antibody (gift of Dr. Heidi Hamm, Vanderbilt University).

ERG recording

[0061] Mice were dark-adapted overnight and anesthetized with sodium pentobarbital injected intraperitoneally prior to testing. Both pupils of each animal were topically dilated with phenylephrine hydrochloride and cyclopentolate hydrochloride, and mice were then placed on a heated platform. Rod dominated responses were elicited in the dark with 10-µs flashes of white light (1.37×10^5 cd/m²) presented at intervals of 1 minute in a Ganzfeld dome. Light-adapted, cone responses were elicited in the presence of a 41 cd/m² rod-desensitizing white

background with the same flashes ($1.37 \times 10^5 \text{ cd/m}^2$) presented at intervals of 1 Hz. ERGs were monitored simultaneously from both eyes with a silver wire loop electrode in contact with each cornea topically anesthetized with proparacaine hydrochloride and wetted with Goniosol, with a subdermal electrode in the neck as the reference; an electrically-shielded chamber served as ground.

[0062] All responses were differentially amplified at a gain of 1,000 (-3db at 2 Hz and 300 Hz; AM502, Tektronix Instruments, Beaverton, OR), digitized at 16-bit resolution with an adjustable peak-to-peak input amplitude (PCI-6251, National Instruments, Austin, TX), and displayed on a personal computer using custom software (Labview, version 8.2, National Instruments). Independently for each eye, cone responses were conditioned by a 60 Hz notch filter and an adjustable artifact-reject window, summed ($n=4-20$), and then fitted to a cubic spline function with variable stiffness to improve signal:noise without affecting their temporal characteristics; in this way we could resolve cone b-wave responses as small as 2 μV .

Statistical analysis

[0063] JMP, version 6 (SAS Institute, Cary, NC) was used to compare cross-sectional ERG amplitudes and implicit times. Repeated - measures analyses with PROC MIXED OF SAS, version 9.3 (SAS Institute) were used for histologic comparisons and for comparing longitudinal ERG data of treated versus untreated eyes.

Patients

[0064] Full-field electroretinographic (ERG) data, obtained from the dataset described by Sharon, et al (2003), for 111 patients with XLRP due to ORF15 RPGR mutations were reviewed to compare b-wave amplitudes to 0.5 Hz white light, which reflect remaining rod + cone function, and to 30 Hz flashes of the same white light, which reflect remaining cone function alone. To determine whether they had rod-cone or cone-rod disease, we calculated the ratio of their amplitude to 0.5 Hz flashes divided by their amplitude to 30 Hz flashes for OD and for OS; the same ratio for the lower limit of normal in our system is $350 \mu\text{V}/50 \mu\text{V} = 7$. For more precise quantification of response amplitudes to 0.5 Hz flashes and to minimize possible effects secondary to the primary photoreceptor degeneration, we focused on those patients ($n=14$) with amplitudes to 0.5 Hz flashes $> 50 \mu\text{V}$ that reflected earlier or milder disease.

ERGs of patients with ORF15 mutations

[0065] For the 14 patients with the most robust responses to 0.5 Hz white flashes, reflecting remaining rod + cone function, amplitudes to that condition ranged from 53 μV to 329 μV OD and from 59 μV to 282 μV OS. Their amplitudes to 30 Hz flashes of the same white light,

reflecting cone function alone and monitored with bandpass filtering and signal averaging for amplitudes $< 10 \mu\text{V}$, ranged from $0.98 \mu\text{V}$ to $23.5 \mu\text{V}$ OD and from $0.95 \mu\text{V}$ to $20 \mu\text{V}$ OS. The ratio of response amplitude to 0.5 Hz flashes divided by response amplitude to 30 Hz flashes had a mean \pm standard error of 47.0 ± 12.7 OD and 48.7 ± 13.0 OS. These mean values were significantly different from 7.0, the value for the ratio based on the lower limits of normal (nonparametric signed-rank test, $p = 0.0004$ OD and $p = 0.001$ OS). In other words, these patients with ORF15 mutations had markedly disproportionate loss of cone function. Examples of these ERGs are shown in Fig. 6.

Example 1. AA V-mediated Expression of human RPGR ORF15

[0066] We constructed two human RPGR ORF15 replacement genes, one with an in frame deletion of 126 codons (the long form, ORF15-L) and the other with an in frame deletion of 314 codons (the short form, ORF15-S). Both were inserted into an AAV8 vector under the control of a human rhodopsin kinase promoter (Fig. 1A) (Khani and others 2007; Sun and others 2010). Subretinal delivery of the two human RPGR ORF15 replacement genes (left eyes) led to the production of recombinant RPGR proteins. By western blotting, 2 weeks following AAV vector administration, the long form of ORF 15 produced an approximately 160-kD protein while the short form of ORF 15 produced an approximately 125-kD protein. Both protein products were smaller than native ORF15 seen in human retinal tissue (approximately 200 kD) (Figs. 1B, C). Both forms of replacement ORF15 appeared as a single band when probed with an antibody against the C-terminus of human RPGR. Under our experimental conditions and the dosages given, the expression levels of ORF 15-S and ORF15-L were comparable. Control eyes (right eyes) received AAV-GFP.

[0067] Both forms of ORF 15 could be seen in the retina of *RPGR*^{-/-} mice by immunofluorescence staining of unfixed cryosections (3 weeks following subretinal injections) and correctly localized to the layer in between the inner and outer segments where the connecting cilia reside. However, the short form (AAV8-ORF15-s) gave much weaker signals (Fig. 2A) than the long form (AAV8-ORF15-l). In well-transduced retinal areas the signal from the long form treated retinas appeared indistinguishable from the WT signal (Fig. 2A, B). Double-labeling with an antibody for the ciliary rootlets, which originate from the proximal ends of basal bodies and extend toward the cell interior and thus serve as an excellent marker for the ciliary region (Hong and others 2003; Yang and others 2002), confirmed the correct subcellular localization of the recombinant RPGR to the connecting cilia (Fig. 2B). In contrast to the similarity in protein expression level determined by western blotting, only the long form of ORF 15 appeared to have a robust signal in every CC matching the number of rootlets, whereas in the short form treated retinas, many rootlets did not have an RPGR signal at their distal ends. Figure 2C shows a bar graph representing RPGR label counts relative to the counts of rooteletin fibers in *Rpgr*^{-/-} mouse retinas treated with either the long or short form of human ORF 15 as well as in untreated wildtype mouse retinas. There was no difference in the mean ratios (RPGR signal count divided by Rootletin fiber count) for the ORF15 long form

versus the wild type (Dunnett's method, $p = .24$) but a significantly lower mean ratio for the ORF15 short form versus the wildtype ($p = .0019$).

[0068] Given the similar level of expression by immunoblotting, this disparity in protein localization at the connecting cilium suggested that perhaps some fraction of the short form of ORF 15 might have mislocalized elsewhere within the photoreceptors. Further analysis by immunostaining of fixed retinal sections, which afforded better preservation of tissues at the expense of signal strength, revealed a pattern of ORF15 mislocalized to photoreceptor inner and outer segments for the short form of ORF 15 (Fig. 2D). No mislocalization was seen for the long form of ORF 15 which had a staining pattern similar to WT. Thus, the lack of staining for the short form RPGR at the CC is due to a reduced ability to localize or be confined at this subcellular compartment, rather than a lower level of expression overall.

Example 2. Human ORF15-I (long form) expression in RPGR null mice promotes rod and cone survival

[0069] To investigate the therapeutic efficacy of the two replacement genes, we evaluated *RPGR*^{-/-} mouse photoreceptors by immunostaining to look for signs of improvement in rod and cone morphology. By 13 months of age (6 months post treatment) there was no obvious difference in rod or cone morphology observed with the short form of human ORF 15 (Fig. 3); both control and ORF15 short form treated eyes had the typical degenerative appearance for this age. Rod and cone outer segments were shortened and disorganized compared to WT eyes with rod opsin mislocalization seen throughout the outer nuclear layer and cone opsin mislocalization additionally in the synaptic layer. The outer nuclear layer, in control and ORF15 short form treated eyes, was also comparably reduced in thickness.

[0070] In contrast, eyes treated with the long form of human ORF15 had rhodopsin expression in rods that was properly partitioned to the outer segments with no obvious signs of mislocalization. Similarly, cone opsin mislocalization was rare in these eyes treated with the longer ORF 15 construct. In addition, ORF15-I treated eyes were found to have more rod and cone cells (with nearly normal-appearing outer segments) than control or ORF 15-S treated eyes.

[0071] Based on these findings longitudinal studies were carried out in mice treated with the long form of ORF 15. To quantify the extent of rescue in ORF15-I treated eyes relative to the control eyes, we measured the thickness of the outer nuclear layer (ONL) and the length of photoreceptor inner /outer segments in fellow eyes of 3 *Rpgr*^{-/-} mice. These were measured in 3 regions of the superior hemisphere and in 3 regions of the inferior hemisphere, each region separated by 600µm and beginning 600 µm to either side of the optic nerve head along the vertical meridian; Repeated-measures full-factorial regression at ages 11 months and 18 months was used to identify differences by eye, hemisphere, and region as main effects, as well as their cross-products to determine whether a treatment effect varied geographically. At

11 months of age, ONL thickness was normally distributed but inner segment/outer segment length was not (Shapiro-Wilk W goodness of fit test, $p = .016$); at 18 months of age, neither ONL thickness nor inner segment/outer segment length was normally distributed ($p = .0011$ and $p = .0002$, respectively). At 11 months of age mean ONL thickness was significantly greater for treated eyes ($48.0 \mu\text{m}$) than for control eyes ($38.0 \mu\text{m}$, $p = .0015$); mean inner segment/outer segment length was also significantly greater for treated eyes ($45.1 \mu\text{m}$) than for control eyes ($29.5 \mu\text{m}$, $p < .0001$, $p < .0001$ for normalized ranks). The treatment benefits with respect to ONL thickness and IS/OS length were comparable for the inferior and superior hemispheres at this age. At 18 months of age the differences in retinal morphology between fellow eyes were even more marked: mean ONL thickness was $22.8 \mu\text{m}$ for treated eyes and $13.7 \mu\text{m}$ for control eyes ($p < .0001$, $p < .0001$ for normalized ranks), while mean inner segment/outer segment length was $19.8 \mu\text{m}$ for treated eyes and $7.3 \mu\text{m}$ for control eyes ($p < .0001$, $p < .0001$ for normalized ranks). At this age we initially observed that the treatment benefit for IS/OS length was significantly greater in the superior retina than in the inferior retina at 18 months ($p = .0036$), but this did not hold up after converting length to normalized ranks ($p = .17$). Figure 4A illustrates ONL thickness and IS/OS length by region for treated and control eyes in the three mice at 18 months of age.

[0072] Figure 4B shows representative light micrographs taken from a representative ORF15-L treated and fellow control eye at 18 months of age. In the control retina, the best-preserved area has only about 2-3 rows of loosely arranged photoreceptor nuclei with shortened and disorganized photoreceptor inner/outer segments. Note that the margins of the inner and outer segments are no longer distinct. The treated retina, on the other hand, has about 5-6 rows of photoreceptor cells throughout, with longer, better organized, and distinct inner and outer segments.

Example 3. Human RPGR ORF15 long-form expression improves rod and cone function

[0073] Retinal function as monitored by full-field rod and cone ERGs was evaluated in a cohort ($n=22$) of RPGR^{-/-} mice from 9-months to 18-months of age. Mice received treatment between 3 and 7 months of age, and follow-up ERGs were recorded no sooner than 6-months following injection. Figure 5A shows rod and cone ERG amplitudes by eye for 16 mice who were tested between 11 and 14 months of age. Control eyes (OD) showed disproportionate loss of cone b-wave amplitude relative to rod b-wave amplitude compared with the lower limits for wild-type mice, as previously observed in this murine model of RPGR^{-/-} mice and evidence for a cone-rod degeneration. In every case but one, the treated eye (OS) had a larger ERG a-wave and b-wave amplitude compared with the fellow control eye (OD), demonstrating improvement of rod and cone photoreceptor function. In fact, more than half of the treated eyes (9/16) had rod b-wave amplitudes that were at or above the lower limit of age-matched WT values (dotted line). Geometric mean values for rod ERG a-wave and b-wave amplitude were $121 \mu\text{V}$ OS and $65 \mu\text{V}$ OD for the a-wave and $482 \mu\text{V}$ OS and $267 \mu\text{V}$ OD for the b-wave. Mean cone ERG b-wave amplitudes was $22 \mu\text{V}$ OS and $11 \mu\text{V}$ OD. These data show an 81-86% improvement of

rod function and a 100% improvement of cone function with AAV- ORF15 treatment for this age range.

[0074] In the full cohort of 22 mice, we used repeated measures longitudinal regression to compare rates of change for rod and cone b-wave amplitudes by eye (Fig. 5B). Estimated mean rates of change were -8.6%/month for rod b-wave amplitude of the control eyes and -3.8%/month for rod b-wave amplitude of the treated eyes; the difference between these two means was significant ($p=0.0001$). Estimated mean rates of change were -5.8%/month for cone b-wave amplitude of the control eyes and -0.8%/month for cone b-wave amplitude of the treated eyes; the difference between these two means was also significant ($p<0.0001$). In addition, the decline in cone b-wave amplitude for the treated eyes was found to be not significantly different from zero ($p = 0.54$), indicating stability in cone function with no observable progression.

[0075] Representative rod and cone ERGs are shown in Fig. 5C to illustrate waveforms in treated and control eyes, including a WT, at 18 months of age (the final time point). Rod function in control eyes at this age is severely reduced (by 75%, on average), while cone function is minimal and in some cases virtually non-detectable. In contrast, treated eyes at this time point still have substantial rod and cone function although below those seen in WT eyes.

PATENTKRAV

1. Nukleinsyre, der koder for et afkortet, humant RPGR-protein, hvor det afkortede, humane RPGR-protein er mindst 95 % identisk med fuldlængden af SEQ ID NO: 2.

2. Nukleinsyre ifølge krav 1, hvor:

nukleinsyren, der koder for det afkortede, humane RPGR-protein er under kontrol af en human rhodopsinkinase- (hRK) promotor; hvor

(a) hRK-promotoren omfatter SEQ ID NO: 5; eller

(b) hRK-promotoren i det væsentlige består af SEQ ID NO: 5.

3. Nukleinsyre ifølge krav 1 eller 2, hvor nukleinsyren koder for et afkortet, humant RPGR-protein, der omfatter SEQ ID NO: 2.

4. Nukleinsyre ifølge et hvilket som helst af krav 1 til 3, hvor nukleinsyren koder for et afkortet, humant RPGR-protein, der består af SEQ ID NO: 2.

5. Nukleinsyre ifølge et hvilket som helst af krav 1 til 4, hvor nukleinsyren, der koder for det afkortede, humane RPGR-protein, er mindst 95 % identisk med fuldlængden af SEQ ID NO: 1.

6. Nukleinsyre ifølge et hvilket som helst af krav 1 til 5 til anvendelse i behandling af et menneske, der har X-bundet retinitis pigmentosa (XLRP) eller en anden oftalmologisk tilstand grundet funktionstabsmutation i det gen, der koder for retinitis pigmentosa-GTPase-regulator- (RPGR) proteinet.

7. Viral vektor, der omfatter nukleinsyren ifølge et hvilket som helst af krav 1 til 5.

8. Viral vektor ifølge krav 7, der er en adenoassocieret, viral vektor, eventuelt hvor den adenoassocierede, virale vektor er AAV2 eller AAV8.

9. Viral vektor ifølge krav 8, hvor den adenoassocierede, virale vektor er AAV2/8.

10. Viral vektor ifølge et hvilket som helst af krav 7-9 til anvendelse i behandling af et menneske, der har X-bundet retinitis pigmentosa (XLRP) eller en anden oftalmologisk tilstand grundet funktionstabsmutation i det gen, der koder for retinitis pigmentosa-GTPase-regulator- (RPGR) proteinet.

5 **11.** Isoleret værtscelle, der omfatter den virale vektor ifølge krav 7 til 9 eller nukleinsyren ifølge et hvilket som helst af krav 1 til 5.

12. Isoleret værtscelle ifølge krav 11, hvor cellen udtrykker det afkortede, humane RPGR-protein.

10 **13.** Adenoassocieret, viral vektor omfattende en nukleinsyre, der koder for et afkortet, humant RPGR-protein, hvor det afkortede, humane RPGR-protein er mindst 95 % identisk med fuldlængden af SEQ ID NO: 2, til anvendelse i behandling af et menneske, der har X-bundet retinitis pigmentosa (XLRP) eller en anden oftalmologisk tilstand grundet funktionstabsmutation i det gen, der koder for retinitis pigmentosa-GTPase-regulator-(RPGR) proteinet.

15 **14.** Viral vektor til anvendelse ifølge krav 13, hvor nukleinsyren, der koder for det afkortede, humane RPGR-protein, er under kontrol af en human rhodopsinkinase- (hRK) promotor.

15. Viral vektor til anvendelse ifølge krav 13 eller 14, hvor:

20 (a) hRK-promotoren omfatter eller i det væsentlige består af SEQ ID NO: 5; og/eller

(b) nukleinsyren, der koder for det afkortede, humane RPGR-protein omfatter eller i det væsentlige består af en sekvens, der er mindst 95 % identisk med SEQ ID NO: 1.

25 **16.** Viral vektor til anvendelse ifølge et hvilket som helst af krav 13-15, hvor den adenoassocierede, virale vektor er AAV2 eller AAV8.

17. Viral vektor til anvendelse ifølge et hvilket som helst af krav 13-15, hvor den adenoassocierede, virale vektor er AAV2/8.

18. Viral vektor til anvendelse ifølge et hvilket som helst af krav 13 til 17, hvor det afkortede, humane RPGR-protein omfatter SEQ ID NO: 2.

19. Viral vektor til anvendelse ifølge et hvilket som helst af krav 13 til 18, hvor det afkortede, humane RPGR-protein består af SEQ ID NO: 2.

20. Viral vektor til anvendelse ifølge et hvilket som helst af krav 13 til 19;

(a) hvor anvendelsen omfatter administration af nukleinsyren i en lav dosis
5 på ca. 2×10^{10} vg/mL, en mellemdosis på ca. 2×10^{11} vg/mL eller en høj dosis på ca. 2×10^{12} vg/mL; og/eller

(b) hvor nukleinsyren administreres i det subretinale rum;

eventuelt hvor en mikroinjektionskanyle indføres i det subretinale rum,
temporalt for synsnerven og lige over de store arkadekar, således at fluidstrøm kan
10 dirigeres mod makula.

SEKVENSLISTE

Sekvenslisten er udeladt af skriftet og kan hentes fra det Europæiske Patent Register.

The Sequence Listing was omitted from the document and can be downloaded from the European Patent Register.
