(57) **ABSTRACT**

A biopsy device and method are provided for obtaining a tissue sample, such as a breast tissue biopsy sample. The biopsy device may include an outer cannula having a distal piercing tip, a cutter lumen, a side tissue port communicating with the cutter lumen, and at least one fluid passageway disposed distally of the side tissue port. The inner cutter may be advanced in the cutter lumen past the side tissue port to sever a tissue sample. After the tissue sample is severed, and before the inner cutter is retracted proximally of the side tissue port, the cutter may be used to alternately cover and uncover the fluid passageway disposed distally of the side tissue.

BIOPSY DEVICE INCORPORATING AN ADJUSTABLE PROBE SLEEVE

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application is a continuation-in-part to U.S. pat. application Ser. No. 11/072,719 entitled "BIOPSY DEVICE WITH VARIABLE SIDE APERTURE" to Weikel et al., filed 04 -Mar.-2005, the disclosure of which is hereby incorporated by reference in its entirety.

FIELD OF THE INVENTION

[0002] The present invention relates in general to biopsy devices, and more particularly to biopsy devices having a cutter for severing tissue.

BACKGROUND OF THE INVENTION

[0003] The diagnosis and treatment of tissue is an ongoing area of investigation. Medical devices for obtaining tissue samples for subsequent sampling and/or testing are known in the art. For instance, a biopsy instrument now marketed under the tradename MAMMOTOME is commercially available from Ethicon Endo-Surgery, Inc. for use in obtaining breast biopsy samples.

[0004] The following patent documents disclose various biopsy devices and are incorporated herein by reference in their entirety: U.S. Pat. No. 6,273,862 issued Aug. 14, 2001; U.S. Pat. No. 6,231,522 issued May 15, 2001; U.S. Pat. No. 6,228,055 issued May 8, 2001; U.S. Pat. No. 6,120,462 issued Sep. 19, 2000; U.S. 6,086,544 issued Jul. 11, 2000; U.S. 6,077,230 issued Jun. 20, 2000; U.S. Pat. No. 6,017,316 issued Jan. 25, 2000; U.S. Pat. No. 6,007,497 issued Dec. 28, 1999; U.S. Pat. No. 5,980,469 issued Nov. 9, 1999; U.S. Pat. No. 5,964,716 issued Oct. 12, 1999; U.S. Pat. No. 5,928,164 issued Jul. 27, 1999; U.S. Pat. No. 10/676,944, "Biopsy Instrument with Internal Specimen Collection Mechanism" filed Sep. 30, 2003 in the name of Hibner et al.; and U.S. patent application Ser. No. 10/732,843, "Biopsy Device with Sample Tube" filed Dec. 10, 2003 in the name of Cicenias et al.

[0005] These generally-known vacuum assisted core biopsy devices include desirable features wherein larger samples are drawn in by vacuum assistance and severed by a cutter. These larger samples have benefits over needle biopsies in obtaining a sample more likely to include at least a portion of a suspicious lesion for diagnostic purposes. In addition, some of these known biopsy devices are capable of taking multiple samples without having to remove the probe. This shortens the duration and inconvenience of the procedure between taking samples. In addition, this facilitates taking sufficient samples to fully excise a suspicious lesion.

[0006] Long side apertures of a probe of these biopsy devices in combination with vacuum assistance, especially with a separate vacuum lumen, have many desirable features. However, there are situations in which lesions near the skin are difficult to biopsy with a core biopsy probe. This is

more often a challenge with a small breast, especially when compressed in a localization fixture that limits the choice in access direction. If the side aperture of the probe is partially exposed, then vacuum assist may be ineffective as the specimen bowl in the probe is exposed to atmospheric pressure. Further, skin may prolapse into the specimen bowl before the cutter advances into the tissue, causing gouging of the skin, increasing post-procedure pain and scarring.

[0007] Consequently, a significant need exists for a core biopsy device that is capable of taking biopsies of a suspicious lesion that is proximate to the skin.

SUMMARY OF THE INVENTION

[0008] The present invention addresses these and other problems of the prior art by providing a core biopsy device having a probe assembly with a side aperture that is selectively longitudinally sized for taking samples. A proximal blocking member may be selectively positioned proximate to the side aperture such that a proximal portion thereof is blocked when otherwise an outer layer of skin would prolapse into the side aperture when a cutter tube is retracted and then be gouged as the cutter is advanced to take a tissue sample. Thereby, discomfort and disfiguring scarring is avoided while still retaining the ability to take a tissue sample of a lesion near to a patient's skin.

[0009] In one aspect consistent with other aspects of the invention, a device for use with a core biopsy includes a curved portion sized to correspond to a portion of the probe surrounding at least the proximal portion of the side aperture which is held thereover by an engaging structure attached to the curved portion and registered to at least partially encompass and engage the probe. A flange attached to the curved portion allows for a user to longitudinally position the curved portion over the proximal portion of the side aperture when desired. Thereby, an additional capability is provided for a biopsy device even when its operation requires that a cutter tube fully retract to remove a tissue sample before a subsequent translation for taking another sample.

[0010] In another aspect of the invention, a transparent sleeve probe is attachable to a needle of a biopsy device and includes a distal inner contour that helps to prevent gouging by an advancing cutter tube so that debris is not introduced into tissue or into the side aperture of the biopsy device.

[0011] In yet a further aspect of the invention, a core biopsy device has a probe sleeve including a curved portion sized to correspond to a portion of the probe of the core biopsy device surrounding at least the proximal portion of the side aperture which is held thereover by an engaging structure attached to the curved portion and registered to at least partially encompass and engage the probe. A flange attached to the curved portion allows a user to longitudinally position the curved portion over the proximal portion of the side aperture when desired. Thereby, an additional capability is provided for a biopsy device even when its operation requires that a cutter tube fully retract to remove a tissue sample before a subsequent translation for taking another sample.

[0012] These and other objects and advantages of the present invention shall be made apparent from the accompanying drawings and the description thereof.

BRIEF DESCRIPTION OF THE DRAWINGS

[0013] While the specification concludes with claims particularly pointing out and distinctly claiming the present invention, it is believed the same will be better understood by reference to the following description, taken in conjunction with the accompanying drawings in which:

[0014] **FIG. 1** is a partial isometric and partial schematic view of a core sampling biopsy system with a handpiece having a long stroke cutter for the collection of soft tissue depicted with a holster separated from a probe assembly;

[0015] **FIG. 2** is an exploded isometric view of the probe assembly of **FIG. 1**;

[0016] **FIG. 3** is an isometric view of the probe assembly with the left handle shell removed, showing the cutter in the first, fully retracted position, and a tissue sample is own deposited onto a tissue sampling surface of the handle after the tissue sample was moved from the distal end of the cutter;

[0017] **FIG. 4** is an exploded isometric view of the holster;

[0018] **FIG. 4A** is a top view in section of the probe assembly and a distal portion of the holster, revealing a cutter in a first, fully retracted position;

[0019] **FIG. 5** is a front view in elevation of the probe and probe sleeve taken in cross section along lines **5-5** of **FIG. 1**;

[0020] **FIG. 6** is an isometric view of the probe sleeve of **FIG. 1**.

[0021] **FIG. 7A** is an isometric view of the probe of the biopsy system of **FIG. 1** with the be sleeve at a proximal position exposing a side aperture;

[0022] **FIG. 7B** is an isometric view of the probe of the biopsy system of **FIG. 1** with the be sleeve at a more distal position partially blocking the side aperture;

[0023] **FIG. 7C** is an isometric view of the probe of the biopsy system of **FIG. 1** with the be sleeve at a most distal position completely blocking the side aperture;

[0024] **FIG. 8A** is a left side view in elevation of the probe and probe sleeve of **FIG. 7B** en along a longitudinal centerline of lines **8-8** with vacuum assistance being employed prolapse tissue into a bowl of the probe;

[0025] **FIG. 8B** is a left side view in elevation of the probe and probe sleeve of **FIG. 7B** en along a longitudinal centerline of lines **8-8** with vacuum assistance being employed prolapse tissue into a bowl and to draw severed tissue into a sample lumen as a cutter e is rotated and translated in a cutter lumen of the probe;

[0026] **FIG. 8C** is a left side view in elevation of the probe and probe sleeve of **FIG. 7B** en along a longitudinal centerline of lines **8-8** with a completely severed tissue sample captured in the sample lumen;

[0027] **FIG. 9** is a perspective view of an alternative probe sleeve for the core sampling biopsy system of **FIG. 1** incorporating a transparent body, measurement indicia and a protective insert to prevent cutter gouging;

[0028] **FIG. 10** is a perspective view of the transparent body of the alternative probe eve of **FIG. 9**;

[0029] **FIG. 11** is a perspective view of the ribbed protective insert for the alternative be sleeve of **FIG. 9**;

[0030] **FIG. 12** is a perspective view of an alternative non-ribbed protective insert for the alternative probe sleeve of **FIG. 9**;

[0031] **FIG. 13** is a perspective view of an alternative transparent body having paired transverse gripping flanges for a further alternative probe sleeve;

[0032] **FIG. 14** is a perspective view of a further alternative transparent body having red radial clip flanges and molded measurement indicia for a yet a further alternative be sleeve;

[0033] **FIG. 15** is a perspective view of an additional alternative transparent body having increased diameter distal portion for an additional alternative probe sleeve;

[0034] **FIG. 16** is a left side view in elevation of the additional alternative transparent body of **FIG. 15** taken in cross section along longitudinal centerline **16-16**;

[0035] **FIG. 17** is a partial isometric and partial schematic view of an alternative biopsy stem that includes a handpiece with a short stroke cutter that is advantageously figured to perform a cutting stroke that blocks a proximal portion of a side aperture of robe for taking biopsy samples near an external surface;

[0036] **FIG. 18** is an isometric view of a probe assembly of the handpiece of **FIG. 17 h** a holster removed;

[0037] **FIG. 19A** is a cross-sectional isometric view of the probe assembly of **FIG. 18** en along line **19-19** with a cutter and carriage assembly positioned at a proximal position;

[0038] **FIG. 19B** is a cross-sectional isometric view of the probe assembly of **FIG. 18** en along line **19-19** with the cutter and carriage assembly positioned between proximal distal end positions;

[0039] **FIG. 19C** is a cross-sectional isometric view of the probe assembly of **FIG. 18** en along line **19-19** with the cutter and carriage assembly positioned at the distal end position;

[0040] **FIG. 20** is an exploded isometric view of the probe assembly of **FIG. 18**;

[0041] **FIG. 21A** is a schematic left side view in elevation of a probe of the probe assembly of **FIG. 18** taken along a longitudinal center line in cross section with a cutter at fully retracted position just proximal to a side aperture of the probe;

[0042] **FIG. 21B** is a schematic left side view in elevation of the probe of the probe assembly of **FIG. 18** taken along a longitudinal center line in cross section with the cutter a partially blocking position within a bowl of the probe below the side aperture, the posed cutter being used to seal an insertion point into tissue as vacuum assist is used to lapse tissue into the distal portion of the side aperture;

[0043] **FIG. 21C** is a schematic left side view in elevation of the probe of the probe assembly of **FIG. 18** taken along a longitudinal center line in cross section with the cutter fully distally translated with vacuum assist being used to both push and pull a severed sue sample in the cutter proximally; and

[0044] FIG. 22 is a left side view in elevation of a distal end of a probe for the probe assemblies of FIGS. 1 and 17 with a reduced length piercing tip.

DETAILED DESCRIPTION OF THE INVENTION

[0045] Core sampling biopsy devices are given additional flexibility to remove tissue samples that reside close to an insertion point by incorporating an ability to block a proximal portion of a side aperture in a probe, corresponding to where the outer tissue layers contact the probe when the distal portion of the side aperture is placed beside a suspicious lesion. This proximal blocking feature may be provided by a separate member attachable to generally-known biopsy devices, leveraging existing capital investments in an economical way. In the first illustrative version, a biopsy device that includes a long stroke cutter that retracts fully out of a probe between samples in order to retrieve tissue samples is thus adapted when a variable sized side aperture is desired. Alternatively, in a second illustrative version, a biopsy device that has tissue sample retrieval that is independent of cutter position is adapted to employ the cutter as the proximal blocking feature to achieve a variable sized side aperture.

[0046] Long Stroke Biopsy Device:

[0047] In FIGS. 1-3, a biopsy system 10, which is described in greater detail in the previously incorporated U.S. Pat. No. 6,273,862, performs a long cutting stroke in combination with vacuum assistance to obtain a plurality of consistently sized core biopsy samples suitable for diagnostic and therapeutic treatments without the necessity of removing a probe (a.k.a. needle, piercer) 12 to retrieve each sample. While retaining a long side aperture (port) 14 in the probe 12 is useful in many instances to retrieve relatively large samples, there are instances in which a suspicious lesion has been imaged proximate to the outer skin. Positioning the probe 12 for such a biopsy would expose a proximal portion of the side aperture 14 outside of the patient's body, defeating pneumatic features of the biopsy system 10. In addition, it should be appreciated that subsequent cutting strokes may gouge away portions of the skin that may prolapse into the side aperture 14, unnecessarily increasing discomfort and scarring at the point of insertion. Advantageously, a proximal aperture blocking member, depicted in the illustrative version of FIG. 1 as a probe sleeve 16, advantageously clips onto the probe 12 and may be distally positioned to selectively cover a proximal portion of the side aperture 14 when desired.

[0048] The biopsy system 10 includes probe assembly 18 that includes a handle 20 proximally attached to the probe 12. The biopsy system 10 further includes a detachable holster 22 that serves as a manual user interface and a mechanical and electrical connection to a control module 24 that may be remotely positioned away from diagnostic systems (e.g., magnetic resonance imaging (MRI)) (not shown). The control module 24 includes a fluid collection system 26, a control unit 28, and a power transmission source 30. The handle 20 is detachably connected to the detachable holster 22. Together they constitute a lightweight, ergonomically shaped, hand manipulatable portion referred to as a biopsy device ("handpiece") 32. The handpiece 32 is fluidly connected to the fluid collection system 26

by a first vacuum tube 34 and a second vacuum tube 36. The first and second vacuum tubes 34, 36 are detachably connected to the fluid collection system 26 by a first connector 38 and a second connector 40, respectively. The first connector 38 has a male portion 42 and a female portion 44 attached to the first vacuum tube 34. The second connector 40 has a female portion 30 and a male portion 26 attached to the second vacuum tube 36. The connector male and female portions, 42-48, are attached in this manner to prevent the accidental switching of the first and second tubes 34, 36 to the fluid collection system 26. The detachable holster 22 includes a first rotatable shaft 50, a second rotatable shaft 52, and a control cord 54. The first and second rotatable shafts 50, 52 are advantageously flexible so that the operator may easily manipulate the handpiece 32 with one hand. The control cord 54 operatively connects the handpiece 32 to the power transmission source 30 and control unit 28.

[0049] The detachable holster 22 and the handle 20 are separated in this depiction for clarity, although it would be appreciated that they would be assembled during operation. A pair of tabs 60, 62 project laterally from each side of a holster upper shell 64, and insert into left and right undercut ledges 66, 68 of a hollow handle housing 70 of the handle 20. A plurality of indentations 72 are provided on the hollow handle housing 70 to improve the operator's grip on the handpiece 32. A tube slot 74 in a lower shell 76 of the holster 22 provides clearance for first and second vacuum tubes 34, 36. A first switch 78, a second switch 80, and a third switch 82 are mounted in the distal portion of the detachable holster 22 so that the physician can operate the handpiece 32 with a single hand while having the other hand free to operate an ultrasonic imaging device or the like. The switches 78, 80, and 82 are provided to operate the power transmission source 30 and the fluid collection system 26 in conjunction with the control unit 28. A ridge 84 on the distal end of the detachable holster 22 is provided to assist the operator in grasping the handpiece 32 and in operating the switches 78, 80, and 82. The ridge 84 further provides the operator with a tactile reference as to where to properly grasp the handpiece 32.

[0050] The handle 20 includes a window 86 so that a portion of the first vacuum tube 34 may be viewed. The first and second vacuum tubes 34, 36 are made from a flexible, transparent or translucent material, such as silicone tubing. This enables visualization of the material flowing through the tubes 34, 36. By having the window 86 in the handle 20, the operator can see the flow in the first vacuum tube 34 without needing to look away from the tissue into which the probe 12 is inserted. A transverse opening 88 is provided in the distal end of the hollow handle housing 70 which allows access from either side to a tissue sampling surface 90. The tissue extracted from the surgical patient is retrieved by the operator or an assistant from the tissue sampling surface 90.

[0051] FIG. 2 is an exploded isometric view of the handle 20. The handle housing 70 is formed from a left handle shell 92 and a right handle shell 94, each injection molded from a rigid, biocompatible plastic such as polycarbonate. Upon final assembly of the handle 20, the left and right handle shells 92, 94 are joined together by ultrasonic welding along adjoining edge 96, or joined by any of several other methods well known in the art.

[0052] The probe 12 includes an elongated cutter tube 98, typically metallic, defining a cutter lumen 100. On the side of the distal end of the cutter tube 98 is the side aperture 14 for receiving the tissue to be extracted from the surgical patient. Joined alongside the cutter tube 98 is an elongated, tubular, metallic vacuum chamber tube 102 defining a vacuum lumen 104. Cutter lumen 100 is in fluid communication with vacuum lumen 104 via a plurality of vacuum holes 106 located in the bottom of a "bowl" 108 defined by the side aperture 14. These holes 106 are small enough to remove the fluids but not large enough to allow excised tissue portions to be removed through the first vacuum tube 34, which is fluidly connected to the vacuum chamber tube 102. A sharpened, metallic distal end 110 is attached to the distal end of the probe 12. It is designed to penetrate soft tissue such as the breast. In this embodiment, the sharpened distal end 110 is a three-sided, pyramidal-shaped point, although the tip configuration may also have other shapes.

[0053] Still referring to FIG. 2, the proximal end of the probe 12 is attached to a union sleeve 112 having a longitudinal bore 114 through it, a widened center portion 116, and a transverse opening 118 through the widened center portion 116. The union sleeve 112 is mounted between the left and right handle shells 92, 94 on a pair of union sleeve ribs 120 projecting from each handle shell 92, 94. An elongated, metallic, tubular cutter 122 is axially aligned within the longitudinal bore 114 of the union sleeve 112 and the cutter lumen 100 of the probe 12 so that the cutter 122 may slide easily in both the distal and proximal directions. A pair of cutter guides 124 are integrally molded into each of the handle shells 92, 94 to slidably retain the cutter 122 in an coaxially aligned position with the proximal end of the cutter tube 98. Cutter 122 has a sample lumen 126 through the entire length of the cutter 122. The distal end of the cutter 122 is sharpened to form a cutter blade 128 for cutting tissue held against the cutter blade 128 as the cutter 122 is rotated. The proximal end of the cutter 122 is attached to the inside of a cutter gear bore 130 of a cutter gear 132. The cutter gear 132 may be metallic or polymeric, and has a plurality of cutter gear teeth 134, each tooth having a typical spur gear tooth configuration as is well known in the art.

[0054] Still in FIG. 2, the cutter gear 132 is driven by an elongated drive gear 136 having a plurality of drive gear teeth 106 designed to mesh with the cutter gear teeth 134. The function of the drive gear 136 is to rotate the cutter gear 132 and the cutter 122 as they translate in both longitudinal directions. The drive gear 136 may be made from a metal such as stainless steel for durability and strength or from a nonferrous material for MRI compatibility. A distal drive axle 138 projects from the distal end of the drive gear 136 and mounts into an axle support rib 140 molded on the inside of the left handle shell 92. A gear shaft 142 projects from the proximal end of the drive gear 136 and is supported by a gear shaft support rib (not shown) also molded on the inside of the left handle shell 92. A left cross pin 146 is attached to the proximal end of the gear shaft 142 as a means for rotationally engaging the drive gear 136.

[0055] Still referring to FIG. 2, a carriage 148 is provided to hold the cutter gear 132 and to carry the cutter gear 132 as it is rotated in the distal and proximal directions. In the illustrative version, the carriage 148 is molded from a rigid polymer and is cylindrically shaped with a threaded bore 150 through it and with a carriage foot 152 extending from

its side. The foot 152 has a recess 154 formed into it for rotatably holding the cutter gear 132 in the proper orientation for the cutter gear teeth 134 to mesh properly with the drive gear teeth 137. The carriage 148 is attached via the threaded bore 150 to an elongated screw 156 which is parallel to the drive gear 136. The screw 156 has a plurality of conventional lead screw threads 158 and may be made from a stainless steel. The rotation of the screw 156 in one direction causes the carriage 148 to move distally, while the reverse rotation of the screw 156 causes the carriage 148 to move proximally. In turn, the cutter gear 132 moves distally and proximally according to the direction of the screw rotation, and the cutter 122 is advanced or retracted. In this version, the screw 156 is shown with a right hand thread so that clockwise rotation (looking from the proximal to distal direction) causes the carriage 148 to translate in the distal direction. It is also possible to use a left hand thread for the screw 156 as long as provisions are made to do so in the control unit 28. A distal screw axle 160 and a proximal screw shaft 162 project from the distal and proximal ends, respectively, of the screw 156. The distal screw axle 160 mounts rotatably in a distal screw support 48 of the right handle shell 94 while the proximal screw shaft 162 mounts rotatably in a proximal screw support 164, also in the right handle shell 94. A right cross pin 166 is attached to the proximal end of the screw shaft 162 as a rotational engagement means.

[0056] FIGS. 2-3 also show the first and second vacuum tubes 34, 36 referred to earlier. The distal end of the first vacuum tube 34 is attached to a polymeric vacuum fitting 168 that inserts tightly into the transverse opening 118 of the union sleeve 112. This allows the communication of fluids in the cutter lumen 100 to the fluid collection system 26. The first vacuum tube 34 is contained within the hollow handle housing 70 in an open space above the screw 156 and drive gear 136, and exits the distal end of the hollow handle housing 70 through an opening 170. The second vacuum tube 36 is fluidly attached to the proximal end of an elongated, metallic, tubular tissue remover 172. The second vacuum tube 36 exits the hollow handle housing 70 alongside the first vacuum tube 34 out the opening 170. A strainer 174 is attached to the distal end of the tissue remover 172 to prevent the passage of fragmented tissue portions through it and into the fluid collection system 26. The tissue remover 172 inserts slideably into the tubular cutter 122. During operation of the biopsy instrument, the tissue remover 172 is always stationary and is mounted between a pair of proximal supports 176 on the inside of the left and right handle shells 92, 94. When the cutter 122 is fully retracted to the first position, the distal end of the tissue remover 172 is approximately even with the distal end of the cutter 122. The distal end of the cutter 122 when at its first, fully retracted position, is slightly distal to a vertical wall 178 which is proximal and perpendicular to the tissue sampling surface 90.

[0057] In FIG. 3, a right access hole 180 is shown in the proximal end of the right handle shell 43. The right access hole 180 provides access to the proximal end of the screw 156 for operational engagement to the power transmission source 30. Similarly, a left access hole (not shown) is provided in the left handle shell 92 to provide access to the proximal end of the drive gear 136 for operational engagement with the power transmission source 30.

[0058] The tissue remover 172 has two functions. First, it helps to evacuate fluids contained in the cutter lumen 100. This is accomplished by the attachment of the second vacuum tube 36 to the proximal end of the tissue remover 172. Since the distal end of the tissue remover 172 is inserted into the cutter lumen 100, the cutter lumen 100 is fluidly connected to the fluid collection system 26. Second, the tissue remover 172 removes tissue from the cutter 122 as follows. When a tissue sample is taken, the cutter 122 advances to the fourth position just distal to the side aperture 14, and a severed tissue portion 184 is captured within the sample lumen 126 in the distal end of the cutter 122. Then the cutter 122 translates to the first position so that the cutter blade 128 is just distal of vertical wall 178. At this position of the cutter 122, the distal end of the tissue remover 172 (which is always stationary) is approximately even with the distal end of the cutter 122. Therefore, any tissue portion of significant size contained within the sample lumen 126 is pushed out of the sample lumen 126 and onto the tissue sampling surface 90. The tissue portion 184 may then be retrieved by the operator or an assistant.

[0059] With particular reference to FIG. 3, an isometric view of the handle 20 with the left handle shell 92 removed reveals the placement of the components described for FIG. 3. Part of the first vacuum tube 34 has also been removed for clarity. The carriage 148 is shown in the fully retracted position so that the cutter 122 is also at the fully retracted, or first position. The cutter blade 128 is slightly distal to the vertical wall 178 on the handle housing 70. The foot 152 of the carriage 148 is adapted to slide along a carriage guide surface 186 on the inside bottom of the hollow handle housing 70. A cutter axial transmission 188 includes the carriage 148, the screw 156, and the screw shaft 162. A cutter rotational transmission 190 includes the drive gear 136, the cutter gear 132, and the gear shaft 142.

[0060] FIG. 4 is an exploded isometric view of the detachable holster 22. The holster upper shell 64 and a holster lower shell 76 are each injection molded from a rigid, biocompatible plastic such as polycarbonate. Upon final assembly, the shells 64, 76 are joined together by screws (not shown) or other types of fasteners well known in the art, into a plurality of alignment holes 192. A gear drive shaft 194 and a screw drive shaft 196 are contained within the proximal, enclosed portion of the detachable holster 22. These shafts extend from a grommet 198 which has a groove 200 for retainably mounting onto a shell edge 202 of both holster upper and lower shells 64, 76, respectively. The grommet 198 rotatably attaches the first rotatable shaft 50 to the gear drive shaft 194 and the second rotatable shaft 52 to the screw drive shaft 196. The first rotatable shaft 50 rotatably inserts into a left bore 204 of the grommet 198. The second rotatable shaft 52 rotatably inserts into a right bore 206. The grommet 198 also provides a strain-relieved attachment of the control cord 54 to the detachable holster 22.

[0061] Still referring to FIG. 4, the gear drive shaft 194 is supported rotatably upon a pair of gear drive mounts 208 formed into a first wall 210 and a second wall 212 of the inside of the upper and lower holster shells 64, 76. The screw drive shaft 196 is likewise supported rotatably on screw drive mounts 214. A left coupler 216 is attached to the distal end of the drive gear shaft 194 and has a left coupler mouth 218 for rotational engagement with the left cross pin 146 attached to the gear shaft 142. When the handle 20 shown in

FIG. 2 is attached to the detachable holster 22, the gear shaft 142 becomes rotatably engaged to the gear drive shaft 194. Similarly, the screw drive shaft 196 has a right coupler 220 with a right coupler mouth 221 which rotatably engages with the cross pin 166 of the screw shaft 162. Each of the left and right couplers 216, 220 have a coupler flange 222, 224 that rotatably insert into thrust slots 226 formed into the corresponding portions of the drive mounts 158, 160. These coupler flanges 222, 224 bear the axial loading of the drive shafts 180, 182.

[0062] With reference to FIGS. 4-4A, the detachable holster 22 further includes a screw rotation sensor 228, available from Hewlett-Packard as part number HEDR-81002P, for providing an electronic signal to the control unit 28 to be described in more detail later. The rotation sensor 228 is mounted within the inside of the holster upper shell 64 and in a position directly above the screw drive shaft 196. A fluted wheel 230 is attached to the screw drive shaft 196 and extends in front of a light emitting diode (not shown) contained within the rotation sensor 228. As the fluted wheel 230 rotates, the interrupted light beams are electronically detected and transmitted back to the control unit 28 to provide information about the rotational speed of the screw drive shaft (cutter tube axial advancement or retraction speed), and the number of screw rotations from the beginning of operation (instantaneous axial position of the cutter 122). Rotation sensor leads 232 pass through the grommet 198 and are part of the bundle of conductors within the control cord 54.

[0063] The detachable holster 22 has the switches 78, 80, 82 mounted on the inside of the holster upper shell 64. The switches 78, 80, 82 are electronically connected to a plurality of conductors 234 contained in the control cord 54. The third switch 82 operates the fluid communication between the handpiece 32 and the fluid collection system 26 and also sets the control unit 28 to respond to various commands; the second switch 80 operates the movement of the cutter 122 in the proximal direction and sets the control unit 28 to respond to various commands; and the first switch 78 operates the movement of the cutter 122 in the distal direction and sets the control unit 28 to respond to various commands. The functions of the switches 78, 80, 82 are not restricted to what has been described for the first embodiment. Also, the physical locations of the switches 78, 80, 82 on the handpiece 32 are not restricted to the locations depicted in FIG. 4.

[0064] Use Of Sleeve To Adjust Side Aperture Of Long Stroke Biopsy Device:

[0065] In FIGS. 5-6, the probe sleeve 16 is shown detached from the biopsy system 10 and advantageously is open along a lower longitudinal portion to allow for snapping onto the probe 14. In particular, a proximal collar 302 has an interrupted figure-eight inner contour 304 (FIG. 5) corresponding to a lateral cross section of the probe 12. A lower opening 306 in the proximal collar 302 flares outwardly into an actuator for manual positioning of the probe sleeve 16. In particular, a finger flange 308 that has a wider arcing opening 310 so that a right lower portion of the proximal collar 302 extends unsupported as a flexible locking lip 312. A distally projecting half tube 314 is attached to the proximal collar 302 and overarches a top portion of the probe 12 with inwardly directed left and right ridges 316,

318 running along each lateral lower edge of the half tube **314** to longitudinally slidingly engage a pinched lateral waist **320** of the probe **12**. The half tube **314** distally terminates in a beveled edge **322** (**FIG. 6**) to provide for smoother insertion at the insertion point into tissue, as illustrated in **FIGS. 7A-7C** wherein the probe sleeve **16** is first proximal to the side aperture **14** (**FIG. 7A**), then slid over a proximal portion of the side aperture **14** to advantageously enable a biopsy procedure to be performed very close to the surface, (**FIG. 7B**) and then slid further forward to completely block the side aperture **14** (**FIG. 7C**).

[0066] In use, in **FIG. 8A**, the probe **12** has been inserted through skin **340** until the side aperture **14** has been placed adjacent to a suspicious lesion **342**. Vacuum pressure as indicated by arrows **344** flows proximally through sample lumen **126**, through the cutter tube **122** and, as indicated by arrows **346**, through vacuum holes **108** in the bowl **106** into the vacuum lumen **104**. The vacuum assistance causes a portion of the suspicious lesion **342** to prolapse into the bowl **106** of the probe **12**. In **FIG. 8B**, the cutter tube **122** is being simultaneously rotated and distally translated to cut a biopsy sample. Vacuum continues to be drawn proximally through sample lumen **126** to assist in drawing in the severed tissue, as depicted by arrows **348**, with vacuum also continuing to be drawn from the vacuum holes **108** in the bowl **106** through the vacuum lumen **104** to maintain the prolapsed tissue in the bowl **106** for cutting. In **FIG. 8C**, the cutter tube **122** has reached its most distal position. The tissue sample **184** is in the process of being transported out of the tissue by retracting the cutter tube **122** proximally just distal of vertical wall **178** as shown in **FIG. 3** until the tissue sample **184** is ejected onto sampling surface **90** via strainer **174** as shown in **FIG. 2**.

[0067] Transparent, Marked Probe Sleeve With Cutter Gouge Protection:

[0068] In **FIGS. 9-11**, an alternative probe sleeve **350** includes a transparent body **352** molded from an MRI compatible material. A half cylindrical tube portion **354** of the transparent body **352** distally terminates in an outer ramped surface **356** for atraumatic insertion into an opening into tissue formed by the biopsy device (not shown in **FIGS. 9-11**). The half cylindrical tube portion **354** is shaped to encompass an upper portion of a needle of a biopsy device having a cross section that is a cylindrical, oval, figure-eight shape. It should be appreciated that various internal contours may be used to correspond to a selected needle. Distal and proximal relieved areas **358**, **360** along a lower right edge of the half cylindrical tube portion **354** define there between a left curved gripping flange **362** that wraps slightly farther than a half circle contour of the distal portion of the half cylindrical tube portion **354** to resiliently lock onto the needle. A rectangular relieved area **364** along a distal lower right edge of the half cylindrical tube portion **354** defines with the proximally spaced right-side recess **366**, which is laterally across from the distal recess **385** on the left side. A right gripping flange **368** (shown in phantom) also wraps slightly under the right side of the needle for additional gripping.

[0069] Alignment and gripping of the half cylindrical tube portion **354** is enhanced by overmolding a transparent thermoplastic portion **370** onto an MRI compatible spine portion **372**, which in the illustrative version is a flat

non-ferromagnetic metal (e.g., titanium) that is stamped and formed into a top spine **374**, pairs of radiating ribs **376** for additional strength and grip and a distal half-cylinder guide **378** that underlies the outer ramped surface **356** and has sufficient longitudinal length to overlay a side aperture. The distal half-cylinder guide **378** serves as protection against gouging of the softer transparent thermoplastic portion **370** by the cutter tube. Thereby, introduction of debris into the side aperture is avoided. The pairs of ribs **376** and/or molded or applied measurement marks **380** into the thermoplastic portion **370** give a visual indication external to the patient as to how far the outer ramped surface **356** has been inserted along the shaft of the needle into tissue. The user performs this adjustment by grasping a half circular disk flange **382** attached along distal edges of a pair of left and right flanking horizontal tabs **384**, **386**, each extending transverse to the proximal end of the half cylindrical tube portion **354**. In **FIG. 12**, an alternative MRI compatible reinforcement portion **390** omits pairs of ribs for some applications.

[0070] In **FIG. 13**, an additional alternative probe sleeve **400** is similar if not identical to that depicted in **FIG. 10** with several exceptions. First, a reinforcement portion is omitted for clarity and/or to denote use of a material resistant to gouging from the cutter tube. An aft portion of a shortened half cylindrical tube portion **402** and the left and right horizontal tabs **384**, **386** are omitted aft of the left curved gripping flange **362**. A heightened half oval flange **404** replaces the half circular flange and is paired with a distally spaced second heightened half oval flange **406** for positioning the probe sleeve **400**. Both flanges **404**, **406** are transverse to the half cylindrical tube portion **402** and longitudinally flank the left curved gripping flange **362**.

[0071] In **FIG. 14**, a further alternative probe sleeve **420** formed of a transparent MRI compatible material includes a half cylindrical tube portion **422** with a distal outer ramped portion **424**. Marking indicia **426** are molded along lateral sides of the half cylindrical tube portion **422**. Left and right recesses **428**, **430** and a proximal edge **432** define there between respective left and right curved gripping flanges **434**, **436** that wrap further around the needle to grip. Longitudinal positioning as well as releasing the left and right curved gripping flanges **434**, **436** is facilitated by left and right clip levers **438**, **440** that flare upwardly and outwardly respectively from the gripping flanges **434**, **436**. Depressing the clip levers **438**, **440** toward each other pries the respective gripping flanges **434**, **436** outwardly out of engagement with a needle (not shown).

[0072] In **FIGS. 15-16**, yet a further alternative probe sleeve **450** is similar if not identical to that depicted in **FIG. 10** with a reinforcement portion omitted. To avoid gouging of the MRI compatible transparent material by the cutter tube, the inner and outer contours of a distal portion **452** of a half cylindrical tube portion **454** are heightened to avoid contact.

[0073] Short Stroke Biopsy Device With Variable Aperture Implementation:

[0074] In the second illustrative version depicted in **FIG. 17**, a short stroke core sampling biopsy system **510** includes a handpiece **530** that may be held comfortably in a single hand, and may be manipulated with a single hand. Handpiece **530** may include a probe assembly **532** and a detachably connected holster **534**. Probe assembly **532** may be

operatively connected to a vacuum source **536**, such as by a first, lateral tube **538** and a second, axial tube **540**. First and second tubes **538**, **540** may be made from a flexible, transparent or translucent material, such as silicon tubing, PVC tubing or polyethylene tubing. Using a transparent material enables visualization of the matter flowing through tubes **538**, **540**.

[0075] First tube **538** may include a Y connector **542** for connecting to multiple fluid sources. A first proximal end of Y connector **542** may extend to a first solenoid controlled rotary valve **544** in a control module **546**, while the second proximal end of the Y connector **542** may extend to a second solenoid controlled rotary valve **548** in control module **546**. The first solenoid controlled rotary valve **544** in control module **546** may be operable to connect either the vacuum source **536** or a compressed air source **550** to lateral tube **538**. It is understood within this specification that compressed air means air pressure at or above atmospheric pressure. In one configuration, when valve **544** is activated, vacuum is supplied to tube **538** from vacuum source **536**, and when valve **544** is not activated, pressurized air from compressed air source **550** is supplied through tube **538**. The solenoid associated with valve **544** may be controlled by a microprocessor **552** in control module **546**, as indicated by dashed line **554**. The microprocessor **552** may be employed to adjust the position of valve **544** automatically based upon the position of a cutter **555** (as shown in FIG. 20) movably supported within probe assembly **532**. The second solenoid controlled rotary valve **548** in control module **546** may be employed to either connect a saline supply **556** (such as a saline supply bag, or alternatively, a pressurized reservoir of saline) to a tube **558** or to seal off the proximal end of tube **558**. For instance, rotary valve **548** may be activated by microprocessor **552** to supply saline when one of switches **560** on handpiece **530** is actuated. When rotary valve **548** is activated, first rotary valve **544** may be automatically deactivated (such as by microprocessor **552**) to prevent the interaction of vacuum and saline within lateral tube **538**. A stopcock **561** may be included in lateral vacuum tube **538** to allow for a syringe injection of saline directly into the tube **538**, if desired. For instance, a syringe injection may be employed to increase the saline pressure in the tube to dislodge any clogs that may occur, such as tissue clogging fluid passageways.

[0076] In one version, axial vacuum tube **540** may be employed to communicate vacuum from source **536** to probe assembly **532** through a tissue storage assembly **562**. Axial tube **540** may provide vacuum through the cutter **555** within probe assembly **532** to assist in prolapsing tissue into a side aperture **564** prior to cutting. After cutting occurs, the vacuum in axial tube **540** may be employed to help draw a severed tissue sample from probe assembly **532** and into tissue storage assembly **562**, as will be described in further detail below.

[0077] Holster **534** may include a control cord **566** for operationally connecting handpiece **530** to control module **546**, and a flexible rotatable shaft **568** connecting the holster **534** to a drive motor **570**. A power source **572** may be employed to provide energy to control module **546** for powering holster **534** via control cord **566**. Switches **560** are mounted on holster upper shell **574** to enable an operator to use handpiece **530** with a single hand. One-handed operation allows the operator's other hand to be free, for example, to

hold an ultrasonic imaging device. Switches **560** may include a two-position rocker switch **576** for manually actuating the motion of the cutter **555** (e.g. forward movement of the rocker switch moves the cutter **555** in the forward (distal) direction for tissue sampling and rearward movement of the rocker switch **576** actuates the cutter **555** in the reverse (proximal) direction. Alternatively, the cutter **555** could be automatically actuated by control module **546**. An additional switch **578** may be provided on holster **534** for permitting the operator to activate saline flow on demand into lateral tube **538** (for instance, switch **578** may be configured to operate valve **548** for providing saline flow to tube **538** when switch **578** is depressed by the user).

[0078] FIG. 18 shows probe assembly **532** disconnected from holster **534**. Probe assembly **532** includes an upper shell **580** and a lower shell **582**, each of which may be injection molded from a rigid, biocompatible plastic, such as polycarbonate. Upon final assembly of probe assembly **532**, upper and lower shells **580**, **582** may be joined together along a joining edge **584** by any of a number of methods well-known for joining plastic parts, including, without limitation, ultrasonic welding, snap fasteners, interference fit, and adhesive joining.

[0079] FIGS. 19A, 19B, 19C, and 20 illustrate probe assembly **532** in greater detail. FIG. 19A depicts a cutter assembly and carriage **586** retracted proximally. FIG. 19B depicts the cutter assembly and carriage **586** partially advanced. FIG. 19C depicts the cutter assembly and carriage **586** advanced distally. With particular reference to FIG. 20, the probe assembly **532** may include a biopsy needle (probe) **588** located at a distal end of a handle **589** of the probe assembly **532** for insertion into a patient's skin to obtain a tissue sample. Needle **588** comprises an elongated, metallic cannula **590**, which may include an upper cutter lumen **592** for receiving the cutter **555** and a lower vacuum lumen **594** for providing a fluid and pneumatic passageway. Cutter **555** may be disposed within cannula **590**, and may be coaxially disposed within cutter lumen **592**.

[0080] Cannula **590** may have any suitable cross-sectional shape, including a circular or oval shaped cross-section. Adjacent and proximal of the distal end of cannula **590** is the side aperture **564** for receiving the tissue to be severed from the patient. The sharpened tip of needle **588** may be formed by a separate endpiece **596** attached to the distal end of cannula **590**. The sharpened tip of endpiece **596** may be used to pierce the patient's skin that the side tissue receiving port may be positioned in the tissue mass to be sampled. piece **596** may have a two-sided, flat-shaped point as shown, or any number of other shapes suitable for penetrating the soft tissue of the patient.

[0081] The proximal end of needle **588** may be attached to a union sleeve **598** having a longitudinal bore **600** there-through, and a transverse opening **602** into a widened center portion of the bore **600**. The distal end of lateral tube **538** may be inserted to fit tightly into transverse opening **602** of union sleeve **598**. This attachment allows the communication of fluids (gas or liquid) between the lower vacuum lumen **594** and the lateral tube **538**.

[0082] The cutter **555**, which may be an elongated, tubular cutter, may be disposed at least partially within upper cutter lumen **592**, and may be supported for translation and rotation within cutter lumen **592**. Cutter **555** may be supported

within vacuum lumen 594 so as to be translatable in both the distal and proximal directions. Cutter 555 may have a sharpened distal end 606 for cutting tissue received in upper cutter lumen 592 through side aperture 564. The cutter 555 may be formed of any suitable material, including without limitation a metal, a polymer, a ceramic, or a combination of materials. Cutter 555 may be translated within cutter lumen 592 by a suitable cutter drive assembly 607 such that distal end 606 travels from a position proximal of the side aperture 564 (illustrated in FIG. 19A) to a position distal of side aperture 564 (illustrated in FIG. 19C), in order to cut tissue received in cutter lumen 592 through the side aperture 564. In an alternative embodiment, an exterior cutter (not shown) may be employed, with the exterior cutter sliding coaxially with an inner cannular needle, and the inner needle may include a side tissue receiving port.

[0083] Union sleeve 598 is supported between probe upper and lower shells 580, 582 to ensure proper alignment between cutter 555 and the union sleeve 598. The cutter 555 may be a hollow tube, with a sample lumen 608 extending axially through the length of cutter 555. The proximal end of cutter 555 may extend through an axial bore of a cutter gear 610. Cutter gear 610 may be metallic or polymeric, and includes a plurality of cutter gear teeth 612. Cutter gear 610 may be driven by a rotary drive shaft 614 having a plurality of drive gear teeth 616 designed to mesh with cutter gear teeth 612. Drive gear teeth 616 may extend along the length of drive shaft 614 so as to engage cutter gear teeth 612 as the cutter 555 translates from a proximal most position to a distal most position, as illustrated in FIGS. 19A-19C. Drive gear teeth 616 may be in continual engagement with cutter gear teeth 612 to rotate cutter 555 whenever drive shaft 614 is rotatably driven. Drive shaft 614 rotates cutter 555 as the cutter advances distally through side aperture 564 for the cutting of tissue. Drive shaft 614 may be injection molded from a rigid engineered plastic such as liquid crystal polymer material or, alternatively, could be manufactured from a metallic or non-metallic material. Drive shaft 614 includes a first axial end 620 extending distally from the shaft 614. Axial end 612 is supported for rotation within probe lower shell 582, such as by a bearing surface feature 622 molded on the inside of the probe shells 580, 582. Similarly, a second axial end 624 extends proximally from rotary drive shaft 614 and is supported in a second bearing surface feature 626, which may also be molded on the inside of probe lower shell 582. An O-ring and bushing (not shown) may be provided on each axial end 620, 624 to provide rotational support and audible noise dampening of the shaft 614 when rotary drive shaft 614 is mounted in probe lower shell 582.

[0084] As shown in FIGS. 19A, 19B, 19C, and 20, a drive carriage 634 is provided in probe assembly 532 to hold cutter gear 610, and carry the cutter gear and attached cutter 555 during translation in both the distal and proximal directions. Drive carriage 634 may be molded from a rigid polymer and has a cylindrically-shaped bore 636 extending axially therethrough. A pair of J-shaped hook extensions 640 extend from one side of drive carriage 634. Hook extensions 640 rotatably support cutter 555 on either side of cutter gear 610 to provide proximal and distal translation of the cutter gear 610 and cutter 555 during proximal and distal translation of drive carriage 634. Hook extensions 640 align cutter 555 and cutter gear 610 in the proper orientation for cutter gear teeth 612 to mesh with drive gear teeth 616.

[0085] Drive carriage 634 is supported on a translation shaft 642. Shaft 642 is supported generally parallel to cutter 555 and rotary drive shaft 614. Rotation of the translation shaft 642 provides translation of the drive carriage 634 (and so also cutter gear 610 and cutter 555) by employing a lead screw type drive. Shaft 642 includes an external lead screw thread feature, such as lead screw thread 644, on its outer surface. The screw thread 644 extends into the bore 636 in drive carriage 634. The screw thread 644 engages an internal helical threaded surface feature (not shown) provided on the inner surface of bore 636. Accordingly, as shaft 642 is rotated, the drive carriage 634 translates along the threaded feature 644 of the shaft 642. The cutter gear 610 and the cutter 555 translate with the drive carriage 634. Reversing the direction of rotation of shaft 642 reverses the direction of translation of the drive carriage 634 and the cutter 555. Translation shaft 642 may be injection molded from a rigid engineered plastic such as liquid crystal polymer material or, alternatively, could be manufactured from a metallic or non-metallic material. Translation shaft 642 with lead screw thread feature 644 may be molded, machined, or otherwise formed. Likewise, drive carriage 634 may be molded or machined to include an internal helical thread in bore 636. Rotation of shaft 642 drives the carriage and cutter gear 610 and cutter 555 in distal and proximal directions, depending upon the direction of rotation of shaft 642, so that cutter 555 translates within probe assembly 532. Cutter gear 610 is rigidly attached to cutter 555 so that the cutter translates in the same direction and at the same speed as drive carriage 634.

[0086] In one version, at the distal and proximal ends of lead screw thread 644, the helical thread is cut short so that the effective pitch width of the thread is zero. At the distal most and proximal most positions of thread 644, translation of drive carriage 634 is no longer positively driven by shaft 642 regardless of the continued rotation of shaft 642, as the carriage effectively runs off thread 644. Biasing members, such as compression coil springs 650a and 650b (FIG. 20), are positioned on shaft 642 adjacent the distal and proximal ends of screw thread 644. Springs 650a/b bias drive carriage 634 back into engagement with lead screw thread 644 when the carriage runs off thread 644. While shaft 642 continues rotating in the same direction, the zero pitch width thread in combination with springs 650a/b cause drive carriage 634 and, therefore, cutter 555 to “freewheel” at the end of the shaft. At the proximal end of the threaded portion of shaft 642, drive carriage 634 engages spring 650a. At the distal end of the threaded portion of shaft 642, drive carriage 634 engages spring 650b. When drive carriage 634 runs off screw thread 644, spring 650a or 650b engages drive carriage 634 and biases drive carriage 634 back into engagement with screw thread 644 of shaft 642, at which point continued rotation of shaft 642 again causes drive carriage 634 to run off screw thread 644. Accordingly, as long as rotation of shaft 642 is maintained in the same direction, drive carriage 634 (and cutter 555) will continue to “freewheel”, with the distal end of cutter 555 translating a short distance proximally and distally as the carriage is alternately biased onto thread 644 by spring 650a or 650b and then run off screw thread 644 by rotation of shaft 642. When the cutter is in the distal most position shown in FIG. 19C, with the distal end 606 of cutter 555 positioned distal of side aperture 564, spring 650b will engage drive carriage 634, and repeatedly urge drive carriage 634 back into engagement

with screw thread 644 when drive carriage 634 runs off screw thread 644. Accordingly, after cutter 555 is advanced such that the distal end 606 of cutter 555 translates distally past side aperture 564 to cut tissue, to the position shown in FIG. 19C, continued rotation of shaft 642 will result in distal end 606 oscillating back and forth, translating a short distance proximally and distally, until the direction of rotation of shaft 642 is reversed (such as to retract cutter 555 distally to the position shown in FIG. 19A). The slight movement of drive carriage 634 into engagement with screw thread 644 and out of engagement with screw thread 644 against the biasing force of spring 650b, causes the distal end 606 of cutter 555 to repetitively reciprocate a short distance within cannula 590, which distance may be about equal to the pitch of threads 644, and which distance is shorter than the distance the cutter travels in crossing side aperture 564. This reciprocal movement of cutter 555 may provide alternate covering and uncovering of at least one fluid passageway disposed distally of side aperture 564, as described below.

[0087] The zero pitch width ends of lead screw thread 644 provide a defined stop for the axial translation of cutter 555, thereby eliminating the need to slow drive carriage 634 (i.e. cutter 555) as it approaches the distal and proximal ends of the thread. This defined stop reduces the required positioning accuracy for drive carriage 634 relative to shaft 642, resulting in reduced calibration time at the initialization of a procedure. The freewheeling of drive carriage 634 at the distal and proximal most positions of translation shaft 642 eliminates the need to rotate shaft 642 a precise number of turns during a procedure. Rather, translation shaft 642 only needs to translate at least a minimum number of turns to insure drive carriage 634 has translated the entire length of lead screw thread 644 and into the zero width thread. Additionally, the freewheeling of drive carriage 634 eliminates the need to home the device, allowing probe assembly 532 to be inserted into the patient's tissue without first being attached to holster 534. After probe assembly 532 is inserted, holster 534 is attached and sampling may be commenced.

[0088] As shown in FIG. 20, a non-rotating rear tube 652 may be provided in which tube 652 may extend proximally from the proximal end of cutter 555 just proximal of cutter gear 610. Rear tube 652 may be hollow, may have substantially the same inner diameter as cutter 555, and may be comprised of the same material as cutter 555. A seal 654 may be positioned between cutter 555 and rear tube 652 to enable cutter 555 to rotate relative to rear tube 652 while providing a pneumatic seal between rear tube 652 and cutter 555. A rear lumen 656 may extend through the length of tube 652 and may be aligned with sample lumen 608 in cutter 555. Rear lumen 656 transports excised tissue samples from sample lumen 608 through probe assembly 532 to tissue storage assembly 562. Sample lumen 608 and rear lumen 656 are axially aligned to provide a continuous, generally straight lined, unobstructed passageway between side aperture 564 and tissue storage assembly 562 for the transport of tissue samples. The inner surfaces of cutter 555 and tube 652 may be coated with a hydro-lubricous material to aid in the proximal transport of the excised tissue samples.

[0089] A lateral extension 658 may be provided and may be supported by and extend distally from rear tube 652 for securing the tube 652 to drive carriage 634. The extension

658 connects tube 652 to drive carriage 634 so that tube 652 translates with cutter 555, and maintains lumens 608, 656 in continuous fluid-tight communication throughout the cutting cycle.

[0090] FIGS. 21A - 21C provide simplified schematic views of the movement of cutter 555 during a cutting cycle of the biopsy system 510. As shown in FIG. 21A, cutter 555 is located at a distal-most position with distal cutting end 606 disposed distally of the distal most edge of the side aperture 564. This position is similar to when the probe assembly 532 is being prepared for insertion.

[0091] With the probe assembly 532 thus positioned, the cutter 555 is retracted a preprogrammed amount, as shown in FIG. 21B. Thereby, the effective side aperture dimension is variably reduced as desired for taking a smaller length sample. The probe (needle) 588 has been inserted to point where an external surface 672 of body tissue 673 encompasses a proximal blocked portion 674 of the side aperture 564 with a distal unblocked portion 675 of the side aperture adjacent to a suspicious lesion 676. As the cutting cycle begins as depicted, a lateral vacuum force (indicated by arrow 677) may be provided in lower vacuum lumen 594. Vacuum force 677 may be transmitted from vacuum source 536 through tube 538 to lower vacuum lumen 594 through a flow path provided by union sleeve 598 (not shown in FIG. 21B). This vacuum force 677 maintains a portion of the suspicious lesion 676 in a prolapsed position inside of the bowl 671 for cutting. Microprocessor 552 may be employed to activate valve 544 to supply vacuum force 682 when switch 576 is actuated by the user to begin moving cutter 555 distally within needle 588. Lateral vacuum force 682 communicates with side aperture 564 through fluid passageways 678 disposed under side aperture 564, and through one or more fluid passageways 679 disposed distally of the side aperture 564.

[0092] Lateral vacuum force 677 may be employed in combination with an axial vacuum force 680 through sample lumen 608 to draw a tissue sample 682 into side aperture 564. After tissue sample 682 is drawn into side aperture 564, cutter 555 may be rotated and simultaneously translated distally to sever the tissue sample 682 from the surrounding tissue. While cutter 555 advances, vacuum forces 677, 680 may be maintained through lower vacuum lumen 594 and sample lumen 608 to draw the tissue sample 682 into the sample lumen 608 as the sample 682 is severed. As shown in FIG. 21B, as cutter 555 advances the cutter 555 slides across fluid passageways 678, successively blocking the lateral vacuum 677 through fluid passageways 678.

[0093] When cutter 555 reaches the distal most position, as shown in FIG. 21C, fluid passageways 678 may be completely blocked by cutter 555. With passageway 679 open, lower vacuum lumen 594 remains in fluid communication with sample lumen 608 through divider 670 despite the blocking of passageways 678.

[0094] A predefined amount of time after cutter 555 reaches its distal most position and begins to freewheel, the solenoid on rotary valve 544 may be deenergized or otherwise controlled by microprocessor 552 to replace lateral vacuum force 677 with forward pressurized air (either atmospheric or greater) as shown by the arrows 682 in FIG. 21C. The pressurized air is discharged through lateral tube 538 to vacuum lumen 594. With port holes 678 closed off by

cutter 555, the pressurized air communicates with upper cutter lumen 592 through fluid passageway 679 to apply a force against the distal face of sample 682. The “push” force acting on the distal face of sample 682 may act in combination with “pull” axial vacuum force 680 provided through sample lumen 608 of cutter 555 to move sample 682 into and through sample lumen 608 of cutter 555, as shown in FIG. 21 C. Alternatively, instead of employing pressurized air to provide a force on the distal face of sample 682, a pressurized liquid, such as saline, may be directed through lower vacuum lumen 594 and fluid passageways 679 to provide the force on the distal face of sample 682. The cutter 555 closes side aperture 564 from the flow of fluid (gas or liquid) so that tissue surrounding the outer cannula and side aperture 564 is not exposed to the fluid.

[0095] As the tissue sample 682 translates proximally through probe assembly 532 towards sample collection assembly 562, cutter 555 may be maintained in a distal most position. Alternatively, cutter 555 may be retracted back through side aperture 564 towards its initial position in preparation for the next cutting cycle. After cutter 555 is retracted to its partially blocking position, and the tissue sample is translated to tissue storage assembly 562, lateral vacuum force 677 is again provided via vacuum lumen 594 to draw the next tissue sample into side aperture 564. During the translation of cutter 555, cutter 555 may operate in conjunction with divider 670 to separate cutter lumen 592 from vacuum lumen 594.

[0096] During the cutting cycle, cutter 555 translates from a point selectively either just proximal of side tissue receiving side aperture 564 or in the partially blocking position to a point just distal of side aperture 564. The severed tissue samples 682 are directed through the length of sample lumen 608 of cutter 555 and out of the proximal end of cutter 555, rather than translating with cutter 555 (with the samples carried in the distal end of the cutter) proximally through needle 588 to eject samples 682 with a knock-out pin, as in some prior devices. Accordingly, the cutting stroke length may be reduced to be just slightly longer than the length of the side aperture 564. With the reduced stroke 25 length, the distal end of cutter 555 (as well as a length of cutter 555) may remain within needle 588 throughout the cutting cycle, eliminating the need to accommodate the full length of cutter 555 within probe housing (handle) 589 and proximal of needle 588. In addition, the reduced cutting stroke length reduces the required length of translation shaft 642, since the shaft need only translate cutter 555 a distance slightly longer than the length of side aperture 564. Reducing the translation shaft length, and eliminating the need to accommodate the cutter length within the probe housing (handle) 589, enables the length of handpiece 530 to be reduced. The time required to acquire each tissue sample is also reduced in the present invention, due to the shortened cutting stroke reducing the time required to advance and retract the cutter through cannula 590.

[0097] It should be appreciated that the biopsy system 510 advantageously supports an effectively reduced side aperture mode when desired. The reduced proximal travel of cutter 555 allows biopsy system 510 to be used on patients where the breast is compressed to a thin cross-section. Under these circumstances, biopsy needle 588 is inserted into the breast and the proximal end of side aperture 564 is not within the breast. The reduced cutter translation length effectively reduces the length of side aperture 564 preventing the sharp distal edge 606 of cutter 555 from contacting

the patient’s skin during each sampling cycle. The reduced cutter translation length may be preprogrammed into the microprocessor 552 located in control module 546 by the user before or during the procedure.

[0098] SHORTENED DISTAL PIERCING TIP: In FIG. 22, a probe 712 for the probe assemblies 18, 532 advantageously includes a piercing tip 720 having a reduced longitudinal length (e.g., approximately 2 mm shorter) than generally-known piercing tips so as to reduce the “dead space” to a distal end 722 of a side aperture 724 in a cutter lumen 726. Generally known dead spaces are often about 8 mm. Thereby, lesions close to the chest wall or the medial side of the breast may be sampled without piercing as far beyond the lesion. The piercing tip 720 may be a flat blade as depicted or a pyramidal tip, a rounded cone with needle point, orthogonally crossing flat blades or other shapes.

[0099] As an alternative approach and apparatus, a piercing tip with a reduced longitudinal length may be incorporated into an obturator that extends out of a sleeve having an open distal end. Once the piercing tip reaches the surgical site, the obturator is removed and replaced with either a blunt ended stylus or a probe of a biopsy device. The blunt distal end thereof may be distally moved to occupy the location previously occupied by the piercing tip to closely approach a skin or chest wall barrier.

[0100] While preferred embodiments of the present invention have been shown and described herein, it will be obvious to those skilled in the art that such embodiments are provided by way of example only. Numerous variations, changes, and substitutions will now occur to those skilled in the art without departing from the spirit and scope of the appended claims. Additionally, each element described in relation to the invention may be alternatively described as a means for performing that element’s function.

[0101] For example, a proximal blocking feature for a side aperture of a core sampling biopsy device may be integral to a probe rather than being a detachable sleeve nor a selectable position of the cutter. For instance, a guillotine door may be slidably attached to the probe, either externally or internally to the probe and either manually positioned or remotely controlled from a handle of the device as desired to shorten the side aperture.

[0102] As another example, a sleeve may include a longitudinally stepped recess such that rotation presents either a blocking position or a nonblocking position, which may be particularly applicable to circular probes. A proximally placed turn wheel on such a sleeve may provide a visual indication of the current position and the direction of rotation to change the condition.

[0103] As another example, a frangibly-attached blocking member may be formed across the proximal portion of the side aperture. When a full-sized sample is planned, this block member may be detached and disposed of.

[0104] As yet another example, a similar probe sleeve may be advantageously used with a biopsy system that does not rely upon vacuum assist (e.g., palpating tissue into the bowl of the probe during ultrasonic imaging).

What is Claimed:

1. A device for selectively blocking a proximal portion of a side aperture in a needle or a core biopsy instrument having a cutter that translates across the side aperture to sever prolapsed tissue, comprising:

- a half cylindrical tube portion having an inner contour corresponding to the side aperture and a proximate upper portion of the needle of the core biopsy instrument;
 - a gripping flange attached to the half cylindrical tube portion positioned to resiliently lock to an underside of a proximate lower portion of the needle; and
 - a finger flange attached to a proximal portion of the half cylindrical tube portion sized for manual longitudinal positioning of the half cylindrical tube portion relative to the side aperture.
2. The device of claim 1, wherein the half cylindrical tube portion comprises a transparent material.
 3. The device of claim 1, wherein the half-cylindrical tube portion comprises a magnetic resonance imaging compatible material.
 4. The device of claim 1, wherein the half cylindrical tube portion further comprises a distal outer ramped surface.
 5. The device of claim 1, wherein a distal portion of the half cylindrical tube portion comprises an inner relieved contour sized to avoid contact with the cutter of the core biopsy instrument.
 6. The device of claim 1, wherein a distal portion of the half cylindrical tube portion comprises an inner metallic guide resistant to damage from the cutter of the core biopsy instrument.
 7. The device of claim 1, wherein the half cylindrical tube portion further comprises measurement indicia.
 8. The device of claim 1, further comprising a metallic reinforcement portion attached to the half cylindrical tube portion.
 9. The device of claim 1, wherein the gripping flange comprises left and right gripping flanges, each gripping flange attached to upwardly and outwardly diverging finger flanges manually depressed together to flare the gripping flanges out of engagement with the needle of the core biopsy instrument.
 10. A device for selectively blocking a proximal portion of a side aperture in a needle or a core biopsy instrument having a cutter that translates across the side aperture to sever prolapsed tissue, comprising:
 - a transparent half cylindrical tube portion having an inner contour corresponding to the side aperture and a proximate upper portion of the needle of the core biopsy instrument, the inner contour including a distal portion operatively configured to avoid damage from the cutter of the core biopsy instrument;
 - a gripping flange attached to the half cylindrical tube portion positioned to resiliently lock to an underside of a proximate lower portion of the needle; and
 - a finger flange attached to a proximal portion of the half cylindrical tube portion sized for manual longitudinal positioning of the half cylindrical tube portion relative to the side aperture.
 11. The device of claim 10, wherein the distal portion of the half cylindrical tube portion comprises an inner relieved contour sized to avoid contact with the cutter of the core biopsy instrument.
 12. The device of claim 10, wherein the distal portion of the half cylindrical tube portion comprises an inner metallic guide resistant to damage from the cutter of the core biopsy instrument.

13. A biopsy device, comprising:
 - a piercing tube having a side aperture proximate to a distal end thereof defining a bowl portion within the piercing tube for receiving prolapsed tissue through the side aperture;
 - a cutter tube longitudinally translatable within the piercing tube;
 - a cutter drive assembly operatively configured to distally translate the cutter tube across the side aperture severing prolapsed tissue; and
 - a probe sleeve selectably positionable across a proximal portion of the side aperture.
14. The biopsy device of claim 13, wherein the probe sleeve comprises a collar selectively detachable from the probe tube.
15. The biopsy device of claim 14, further comprising:
 - a vacuum assistance system; and
 - a vacuum lumen attached along a length of the piercing tube in fluid communication with the bowl portion thereof forming a vacuum assisted probe and the vacuum assistance system;
 wherein the probe sleeve further comprises a circumferential portion shaped to engage the piercing tube and vacuum lumen.
16. The biopsy device of claim 2, wherein the probe sleeve includes a proximally attached actuator shaped to be grasped by a user.
17. The biopsy device of claim 13, wherein the cutter lumen includes a piercing tip wherein a dead space longitudinal distance from a distal end of the side aperture to a distal-most end of the piercing tip is less than 7.8 mm.
18. The biopsy device of claim 17, wherein the dead space longitudinal distance is approximately 6 mm.
19. The device of claim 13, wherein the half cylindrical tube portion comprises a transparent material.
20. The device of claim 13 wherein the half-cylindrical tube portion comprises a magnetic resonance imaging compatible material.
21. The device of claim 13, wherein the half cylindrical tube portion further comprises a distal outer ramped surface.
22. The device of claim 13, wherein a distal portion of the half cylindrical tube portion comprises an inner relieved contour sized to avoid contact with the cutter of the core biopsy instrument.
23. The device of claim 13, wherein a distal portion of the half cylindrical tube portion comprises an inner metallic guide resistant to damage from the cutter of the core biopsy instrument.
24. The device of claim 13, wherein the half cylindrical tube portion further comprises measurement indicia.
25. The device of claim 13, further comprising a metallic reinforcement portion attached to the half cylindrical tube portion.
26. The device of claim 13, wherein the gripping flange comprises left and right gripping flanges, each gripping flange attached to upwardly and outwardly diverging finger flanges manually depressed together to flare the gripping flanges out of engagement with the needle of the core biopsy instrument.
