(57) **ABSTRACT**
Techniques and mechanisms for exchanging information between a memory controller and a memory device. In an embodiment, a memory controller receives information indicating for a memory device a threshold number of pending consolidated activation commands to access that memory device. The threshold number indicated by the information is less than a theoretical maximum number of pending consolidated activation commands, the theoretical maximum number defined based on timing parameters of the memory device. In another embodiment, the memory controller limits communication of consolidated activation commands to the memory device based on the information indicating the threshold number.

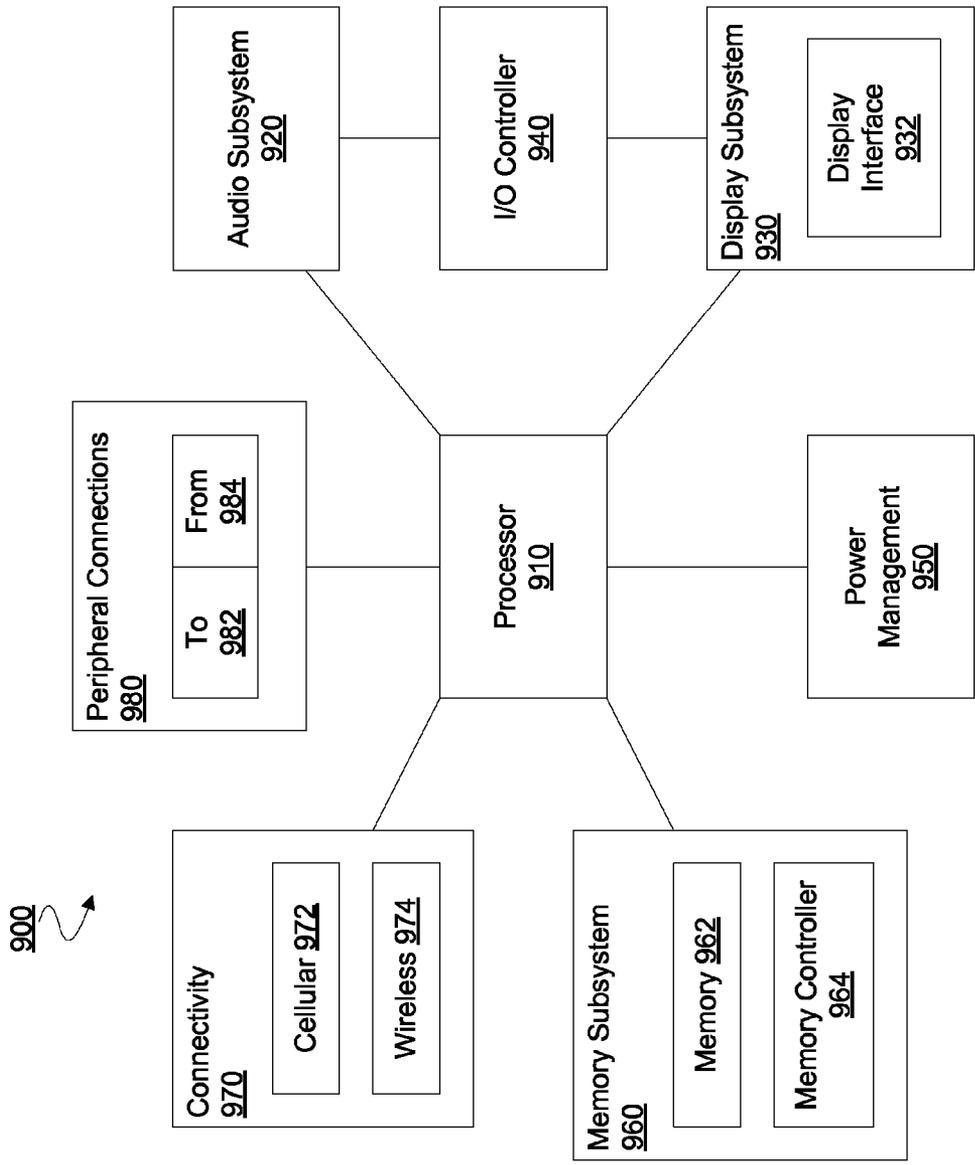

FIG. 9

METHOD, APPARATUS AND SYSTEM TO MANAGE IMPLICIT PRE-CHARGE COMMAND SIGNALING

BACKGROUND

1. Technical Field

The present invention relates to memory devices and, more particularly, to accessing memory cells of a volatile memory device.

2. Background Art

Computing systems generally rely on memory devices to store information. Such memory devices may be divided into two general types. First, volatile memory devices which require power to maintain correctness of the stored information. Second, non-volatile memory devices which maintain the stored information even after power is cut off.

One common type of volatile memory device is Dynamic Random Access Memory (DRAM). DRAM devices generally provide significantly improved performance over mechanical storage devices (such as hard disks), while providing lower cost, higher storage densities and less power consumption in comparison to other memory technologies, including and most notably, static random access memory (SRAM) devices. However, these benefits come at the cost of incurring various delays in accessing the memory cells making up a DRAM device, both at regular intervals, and in the time periods immediately before and after each access to either read data from the memory cells or to write data to the memory cells.

DRAMs generally store each bit of data in a separate capacitor within an integrated circuit. Since capacitors leak charge, the information eventually fades unless the capacitor charge is refreshed periodically. Because of this refresh requirement and other design considerations, DRAMs designers impose various timing constraints on operations within a DRAM to maintain correctness. One such constraint is a precharge requirement. In particular, when access is requested to a different row (also referred to as a Bit Line (BL)) in a DRAM, the current row has to be first deactivated by issuing a “precharge” command. The precharge command will cause the sense amplifiers to switch off and the bit lines to be precharged to matching voltages that are intermediate between high and low logic levels. After a certain row precharge time period delay (also referred to as tRP), an “activate” command may be issued to activate the next row to be accessed.

BRIEF DESCRIPTION OF THE DRAWINGS

The various embodiments of the present invention are illustrated by way of example, and not by way of limitation, in the figures of the accompanying drawings and in which:

FIG. 1 is a high-level functional block diagram illustrating elements of a system for providing memory accesses according to an embodiment.

FIG. 2 is a high-level functional block diagram illustrating elements of a memory controller for generating memory access commands according to an embodiment.

FIG. 3 is a high-level functional block diagram illustrating elements of a memory device to provide access to memory resources in response to memory commands according to an embodiment.

FIG. 4 is a flow diagram illustrating elements of a method for operating a memory device according to an embodiment.

FIG. 5 is a flow diagram illustrating elements of a method for generating memory control commands according to an embodiment.

FIG. 6 is a timing diagram illustrating elements of an exchange of explicit pre-charge command signaling according to an embodiment.

FIG. 7 is a timing diagram illustrating elements of an exchange of implicit pre-charge command signaling according to an embodiment.

FIG. 8 is a high-level functional block diagram illustrating elements of a computing system for accessing memory resources according to an embodiment.

FIG. 9 is a high-level functional block diagram illustrating elements of a mobile device for accessing memory resources according to an embodiment.

DETAILED DESCRIPTION

Embodiments discussed here in variously provide techniques and/or mechanisms to limit communication of at least one type of consolidated commands from a memory controller to a memory device. In one such embodiment, the memory controller includes circuitry to receive information indicating a threshold number of consolidated commands that may be pending at any given time at the memory device. The threshold number may be distinguished from—e.g., less than—a theoretical maximum number of concurrently pending consolidated commands. Such a theoretical maximum may be defined, for example, based on timing parameters that characterize operation of the memory device.

Certain embodiments are discussed herein with respect to a particular type of consolidated command, referred to herein as a “consolidated Activate/implicit Precharge” command (or simply an “ACT/iPRE” command). However, such discussion may be extended to additionally or alternatively apply to any of a variety of other types of consolidated commands, according to different embodiments. A consolidated ACT/iPRE command is to explicitly specify to a memory device the performance of an activation operation—e.g., to open a row of memory. However, due to functionality available at the memory device, hint information included in such a consolidated ACT/iPRE command may be further interpreted as implicitly commanding the performance of an additional precharge operation—e.g., to close a different row of memory that is already open.

It is refresh operations, precharge operations, activate operations as well as other maintenance operations that impose the various delays that are suffered as a result of employing DRAM technology. These delays have the effect of limiting the rate at which data may be written to or read from DRAM devices. Moreover circuitry to coordinate memory accesses according to DRAM timing constraints uses valuable integrated circuit (IC) real estate and adds to production costs. Although existing memory devices include circuitry to support co-pending ACT/iPRE commands, conventional memory architecture design does not contemplate the possibility that—where co-pending ACT/iPRE commands are supported—such circuitry might support less than a theoretical maximum number of ACT/iPRE commands otherwise defined by the memory controller based on the memory device’s timing parameters. To date, it has been generally accepted as a design constraint that a memory device must accommodate the theoretical maximum of ACT/iPRE commands that a memory controller could potentially send according to the timing parameters of that memory device.

Certain embodiments arise from a realization that mechanisms may be provided to set a limit on the allowable number of co-pending ACT/iPRE commands that is less than a theoretical limit defined based on timing parameters. Such embodiments allow a memory device to avoid diminishing returns, in terms of space efficiency and/or other resource efficiency, that are associated with providing support at a memory device for incrementally larger numbers of co-pending ACT/iPRE commands.

FIG. 1 illustrates elements of a system 100 for exchanging commands to access memory resources according to an embodiment. System 100 may include memory device 110 coupled to memory controller 120—e.g. where memory controller 120 is to provide access to memory device 110 for a host processor 140 which is included in or coupled to system 100.

Memory device 110 may include any of a variety of types of memory technology that, for example, have rows of memory cells, where data is accessible via a wordline or the equivalent. In one embodiment, memory device 110 includes dynamic random access memory (DRAM) technology. Memory device 110 may be an integrated circuit package within a larger memory device (not shown) of system 100. For example, memory device 110 may be a DRAM device of a memory module such as a dual in-line memory module (DIMM).

Memory device 110 may include memory resources 114, which represent one or more logical and/or physical groups of memory. An example of one such grouping of memory is a bank of memory resources which, for example, may include an array of storage elements arranged in rows and columns. Memory device 110 may include access logic 118 to facilitate, at least in part, access to memory resources 114—e.g. where such access is provided for servicing one or more commands from memory controller 120. Access logic 118 may include, or operate in conjunction with, logic of memory device 110 which provides resource access according to conventional techniques—e.g. where functionality of threshold indication logic 112, monitor logic 116 and/or access logic 118 supplements such conventional techniques with additional functionality discussed herein. For example, threshold indication logic 112 may communicate information indicating a threshold number of pending ACT/iPRE commands for memory device 110. Alternatively or in addition, monitor logic 116 may detect that a given ACT/iPRE command indicates both an activation operation to be performed and a precharge operation to be performed.

Memory controller 120 may send commands or instructions to memory device 110 over one or more buses, as represented by the illustrative command/address (CA) bus 165. Such commands may be interpreted by memory device 110—e.g. including memory device 110 decoding command information to perform a variety of access functions within the memory and/or decoding address information with column logic and/or row logic. For example, such logic may access a specific location in memory resources 114 with a combination of a column address strobe or signal (CAS) and a row address strobe or signal (RAS). Rows of memory may be implemented in accordance with known memory architectures or their derivatives. Briefly, a row of memory resources 114 may include one or more addressable columns of memory cells, as identified by the CAS generated by column logic of memory 110. The rows may each be variously addressable via the RAS generated by row logic of memory 110.

Access to memory resources 114 may be for the purpose of writing data exchanged—and/or reading data to be

exchanged—via a data bus coupled to I/O circuitry (not shown) of memory 110. For example, N data bus signal lines DQ(1:N) 160 may couple such I/O circuitry to memory controller 120 and/or one or more other memory devices (not shown).

In an embodiment, memory controller 120 includes command logic 135—e.g. including any of a variety of hardware logic and/or executing software logic—to send commands via CA 165. Command logic 135 may include or couple to logic of memory controller which performs operations to generate, transmit or otherwise determine commands sent according to one or more conventional techniques. By way of illustration and not limitation, command logic 135 may supplement otherwise conventional command/address signaling functionality which, for example, conforms to some or all requirements of a dual data rate (DDR) specification such as the DDR4 SDRAM JEDEC Standard JESD79-4, September, 2012 or the like. For example, memory controller 120 may include monitor logic 130 comprising circuitry and/or executing software configured to determine a type of a command signaling to be asserted by (e.g. sent from) command logic 135. Monitor logic 130 may control such command signaling to accommodate a limited command response capability of memory 110.

In an embodiment, monitor logic 130 includes, maintains or otherwise has access to information indicating a command response capability of memory 110, information indicating a status of pending operations within memory 110 and/or information indicating one or more yet-to-be-served accesses to memory device 110. Such information may provide an indication of whether or not a row to be accessed in a given bank of memory device 110 is already open, and if not, whether or not a different row in the same bank is already open. If the row to be accessed is determined to already be open, then the access may be carried out without the transmission of a row activate (ACT) command. However, if the row to be accessed is determined to not already be open, then command logic 135 may transmit to memory device 110 an activate command (e.g. a row activate command) which includes a value specifying whether a bank targeted by the command includes a row which is currently open. Such a value (referred to herein as hint information) may indicate to the memory device 110 that it is to internally generate its own implicit precharge (iPRE) command to perform a precharge operation to close the currently open row—e.g. independent of memory device 110 receiving any explicit command to perform such precharge operation. Alternatively or in addition, monitor logic 130 (and/or other logic of memory controller 120) may access such information to determine—for example—how many commands of a particular type are currently pending at memory 110—e.g., where a pending command is one that memory 110 has received but has not yet completed servicing.

Alternatively or in addition, memory device 110 may include monitor logic 116 to evaluate some or all of a command received via CA 165—e.g. to determine whether a command is further implicitly indicating that another command is to be generated internally by memory device 110. By way of illustration and not limitation, monitor logic 116 may determine whether a command is targeting a bank which includes a page which is currently open. The targeting of such a bank is referred to as a “page miss event” (or, for brevity, simply a “page miss”). In response to monitor logic 116 identifying a page miss event corresponding to a command received via CA 165, monitor logic 116 may perform operations to prepare for accessing of memory resources

targeted by the command. As discussed herein, such operations may include memory device **110** internally generating signaling to function in the place of one or more commands received from memory controller **120**. For example, memory **110** may provide to access logic **118** signals which are functionally equivalent in one or more respects with a precharge (PRE) command from memory controller **120**. Accordingly, access logic **118** may perform operations to precharge a row (or rows) of memory resources **114** independent of memory **110** receiving any explicit PRE command specifying such precharge operations.

For the sake of brevity, “ACT/iPRE” is used herein to refer to an ACT command that implicitly indicates to a memory device that an iPRE is also to be implemented (in addition to the activation operation indicated). Servicing of such an ACT/iPRE command by a memory device requires monitoring circuitry to assure that timing constraints of the memory device are not violated. For example, such constraints may include a timing parameter tRP representing a required time to perform a memory precharge operation and/or a timing parameter tRRD representing a required time between successive activation operations. The timing requirements may impose a theoretical limit on the total number of ACT/iPRE commands which can be concurrently pending at a memory device. By way of illustration and not limitation, the total number of copending ACT/iPRE commands may be based on a total number of tRP time periods that can take complete during a tRRD time period.

FIG. 2 illustrates elements of a memory controller **200** according to an embodiment to generate memory access commands based on an identified limit to a command response capability of a memory device. Memory controller **200** may control access to memory resources such as those of memory device **110**. In an embodiment, memory controller includes some or all of the features of memory controller **120**.

FIG. 2 may include circuitry, as represented by the illustrative read request queue **215** and write request queue **22**, to receive requests to access a memory device (not shown). Read requests from read request queue **215** and write requests from write request queues **220** may be provided to command circuitry **230** configured to select, schedule and/or otherwise determine commands to implement memory accesses in response to these requests. Mode selection circuitry **225** may decide whether command circuitry **230** should be in one of multiple possible modes—e.g., based at least in part on a state of a memory device (e.g., an IC die, not shown) that is coupled to memory controller **200**. In such a first mode, command circuitry **230** may schedule a precharge (PRE) command and an activation (ACT) command as separate single commands. In a second such mode, command circuitry **230** may instead schedule a consolidated ACT/iPRE command. Commands scheduled by command circuitry **230** may be provided by transmitters **240** to a link **205** coupling memory controller to the memory device. Transmitters **240** are one example of an I/O interface to link **205**. Memory controller **200** may also include receivers **245** to receive signals from the memory device via a link **210**. There may be additional modes of memory controller, according to various embodiments.

In some embodiments, memory controller **200** includes monitor circuitry **235** configured to monitor an activity and/or other state of a memory device coupled to memory controller **200**, and based on the monitoring, to provide a state indicator that is indicative of the state. In different embodiments, monitor circuitry **235** interfaces with different circuits. Dashed lines show different possibilities for differ-

ent embodiments. For example, in some embodiments, monitor circuitry **235** monitors signals associated with command circuitry **230**, in other embodiments monitor circuitry **235** monitors signals associated with transmitters **240**, and in yet other embodiments monitor circuitry **235** monitors signals associated with receivers **245**. In still other embodiments, monitor circuitry **235** could monitor signals associated with other circuitry and/or a combination of command circuitry **230**, transmitters **240** and/or receivers **245**.

The state indicator provided by monitor circuitry **235** may be a single signal such as a single bit or a multi-bit number, or it may a combination of signals indicating different aspects of the signals associated with the circuits. In some embodiments, monitor circuitry **235** provides the state indicator directly to mode selection circuitry **225** and in other embodiments, there is intermediate circuitry.

The following are some examples of monitored state and provided state indicators. In some embodiments, monitoring with monitor circuitry **235** includes monitoring consolidated ACT/iPRE commands which are sent from memory controller **200** to a given memory IC or other memory device—e.g., via links **205**. Alternatively or in addition, such monitoring may include monitoring acknowledgements and/or other responses received in response to such consolidated ACT/iPRE commands—e.g., where such acknowledgements and/or other responses are received via links **210**. For each of some or all such ACT/iPRE commands, monitor circuitry **235** may monitor a period of time that has expired since a particular stage of communication and/or processing of the ACT/iPRE command. Alternatively or in addition, such monitoring may include maintaining a count of a total number of consolidated ACT/iPRE commands that are currently pending (e.g., received but not yet serviced) at a particular memory device.

In an embodiment, mode selection circuitry **225** receives or otherwise detects information indicating, for a particular memory device, a threshold total number of consolidated ACT/iPRE commands that may be currently pending at that memory device at any given time. Based on such information, mode selection circuitry **225** may include (e.g., store), have access to or otherwise be configured based on a value of such a threshold number—as represented by the illustrative TR **255**. By way of illustration and not limitation, TR **255** may be determined in response to a communication **250** received by memory controller **200** during (for example) a stage of fabrication, packaging, assembly or other processing to produce a system including memory controller **200** and the memory device. Communication **250** may be received from the memory device itself—e.g., via links **210**—although certain embodiments or not limited in this regard. In another embodiment, communication **250** is received during operation of memory controller **200** as part of a memory system. For example, memory controller **200** may receive communication **250** during a boot-up, wake-up or other power state transition of such a system.

In different embodiments, memory controller **200** may use different approaches to decide whether to be in the first or second mode. For example, monitor circuitry **235** may provide to mode selection circuitry **225**, directly or indirectly, a state indicator indicating a current total number of ACT/iPRE commands that are currently pending at a particular memory device (e.g., a memory IC) coupled to memory controller. Based on such a state indicator, mode selection circuitry **225** may evaluate whether the memory device is currently capable of receiving a next ACT/iPRE command. In some embodiments, mode selection circuitry **225** compares the state indicator provided by monitor cir-

circuitry 235 to TR 255. If the state indicator has a first relationship with TR 255 (for example, greater than or greater than or equal to), then the first mode of command circuitry 230 is configured, during which command signaling to indicate an activation operation and a precharge operation is performed with an ACT command and an explicit PRE command that is distinct from that ACT command. If the state indicator has a second relationship with TR 255 (for example, less than or less than or equal to), then the second mode of command circuitry 230 is configured, during which a consolidated ACT/iPRE command is used to indicate both an activation operation and a precharge operation.

FIG. 3 illustrates details of memory device 300 according to some embodiments, although the inventions are not limited to these details. Memory device 300 represents one example of a memory chip, package or other such device to communicate to a memory controller (not shown) a maximum allowable number of copending consolidated ACT/iPRE commands for the memory device. Such a maximum allowable number may be less than a theoretical maximum that, for example, the memory controller might otherwise operate based on timing constraints of the memory device. Memory device 300, which may include some or all of the features of memory device 110 for example, may exchange threshold information with memory controller 200, in one embodiment.

As illustrated in FIG. 3, signals from a link 305 may be received by receivers 310 and variously provided to components to facilitate access to memory resources of memory device 300. By way of illustration and not limitation, write access information may be communicated to signal separation circuitry 315, including write data that is provided to a write buffer (WB) 330 and one or more commands to be provided to command processing circuitry 320. The write data may remain in write buffer 330 until an associated command and address causes it to be written into banks 335. Banks 335 may include respective memory arrays and further include or couple to various other circuitry—such as sense amplifiers, row and/or column decoders and/or the like—to provide access to such memory arrays. Decoders may also be included before banks 335. Some embodiments do not include a write buffer to hold write data in this manner. In a read access, banks 335 returns read data to internal data link 340. Transmitters 345 receive read data from link 340 and provide it to external link 350.

If a particular received command is a single activate (ACT) command, then command processing circuitry 320 provides the particular ACT command to banks 335 as a single command. However, if the read or write command is a consolidated ACT/iPRE command, then command processing circuitry 320 translates the consolidated ACT/iPRE command into two single commands—i.e., an ACT command and a distinct iPRE command, each to be provided separately to banks 335.

At a given time, the servicing of multiple consolidated ACT/iPRE commands may be taking place concurrently at memory device 300. Command processing circuitry 323 include or couple to circuitry, as represented by the illustrative tracker logic 325, that is to determine how the assertion of an iPRE command and/or an ACT command is to take place based on a consolidated ACT/iPRE command received from the memory controller. Such tracker logic may include, for example, a registry including entries for each pending consolidated ACT/iPRE command. Each such registry may store address and/or timer information indicating an ACT command to be asserted (or a timing thereof) for

the corresponding consolidated ACT/iPRE command. Tracker logic 325 may further comprise monitoring circuitry to variously detect, for each pending consolidated ACT/iPRE command, whether a time period has expired to allow such an ACT command to be asserted.

Certain embodiments provide for memory device 300 to communicate to a host—e.g., to a memory controller—that a total number of allowable copending consolidated ACT/iPRE commands is less than a theoretical maximum that otherwise might be implemented according to timing parameters of memory device 300. By way of illustration and not limitation, memory device 300 may include capability logic 360 (e.g., threshold indication logic 112) comprising circuitry to store or otherwise provide information indicating a command response capability of memory device 300. For example, capability logic 360 may include or otherwise have access to a value TR 365 specifying or otherwise indicating such a total number of allowable copending consolidated ACT/iPRE commands.

For example, TR 365 may specify a maximum total number of allowable copending ACT/iPRE commands. Alternatively or in addition, TR 365 may specify a manufacturing number, model number or other product-specific identifier, wherein the memory controller includes or otherwise has access to reference information (such as a look-up table) to correspond such an identifier to a threshold number of allowable copending consolidated ACT/iPRE commands. Any of a variety of other values may be additionally or alternatively included in TR 365 to facilitate the identification of such threshold information at a memory controller, according to different embodiments. Capability logic 360 may detect connectivity of memory device 300 to the host and, in response, send TR 365 in a communication 370 to the memory controller. Communication 370 may be exchanged via external link 350, for example.

FIG. 4 illustrates elements of the method 400 to configure memory accesses according to an embodiment. Method 400 may be performed by a memory system including some or all of the features of system 100, for example. In one embodiment, method 400 includes both operations 410 performed at a memory device and operations 440 performed at a memory controller that is coupled to such a memory device. However, in an alternate embodiment, method 400 includes only operations 410 or only operations 440.

Operations 410 may comprise, at 420, detecting connectivity of the memory device to the memory controller. The detecting at 420 may take place during a fabrication, assembly or other manufacturing stage of the memory system. Alternatively, the detecting at 420 may take place during or in response to a power state transition of the memory system. In response to detecting the connectivity at 420, method 400 may send to the memory controller, at 430, information indicating a threshold level of a command response capability.

For example, the memory device may send information indicating a threshold number of consolidated activation commands that may be pending at the memory device at any given time. Such a threshold number may be less than a theoretical maximum number of pending consolidated activation commands—e.g. where the theoretical maximum number might otherwise be identified by the memory controller based on timing parameters of the memory device. In one embodiment, the theoretical maximum number is defined based on a timing parameter tRP that represents a minimum time necessary for the memory device to perform a memory precharge operation. Alternatively or in addition,

the theoretical maximum number may be defined based on a timing parameter tRRD representing a minimum time necessary between successive activation operations. The threshold number may be greater than one, although certain embodiments are not limited in this regard.

In one embodiment, the indication sent at **430** includes the actual threshold number of pending consolidated activation commands. In another embodiment, the indication sent at **430** includes a product identification number, wherein the memory controller accesses reference information based on the product identification number to determine the threshold number of pending consolidated activation commands. Operations **440** may include, at **450**, the memory controller receiving from the memory device the information sent at **430**. Based on the indication of the threshold level, the memory controller may, at **460**, limit communication of consolidated ACT/iPRE commands to the memory device. For example, a determination as to whether a consolidated ACT/iPRE command is to be sent—e.g., rather than an explicit PRE command and a distinct ACT command—may be made by the memory controller based on the indicated threshold level and a current total number of consolidated ACT/iPRE commands that are pending at the memory device.

FIG. **5** is a flow chart illustrating features of a method **500** for controlling a memory device according to an embodiment. Method **500** may be performed by one of memory controllers **120**, **200**, for example. In an embodiment, method **500** includes or is in addition to operations **440** of method **400**.

Command circuitry of the memory controller may consider a next access request to service (operation **510**). The access requests under consideration for the purpose of method **500** are those for which servicing requires at least an activation operation to open a row in memory for subsequent access, and potentially an additional precharge operation to close a previously opened row in memory. A determination may be made, at **520**, as to whether a precharge operation is needed to service the request. The determining at **520** may be based, at least in part, on a location in memory that is targeted by the access request retrieved at **510**. For example, if the access to be serviced targets a row in memory that is currently open, then no precharge operation needs may need to be performed to close a different row, and method **500** may generate an ACT command at **550** (independent of any implicit or explicit indication that a precharge operation is to be performed).

However, if the determining at **520** indicates that a precharge operation is needed, then method **500** may determine whether to send ACT and PRE commands that are distinct from one another, or instead send a consolidated ACT/iPRE. For example, method **500** may include mode selection circuitry of the memory controller evaluating at **530** whether a threshold condition is satisfied by a current total number of consolidated ACT/iPRE commands pending at the memory device.

In some embodiments, if the number of ACT/iPRE commands currently pending at the memory device has a first relationship to a threshold number (e.g., greater than, or greater than or equal to), then the mode selection circuitry may configure a first mode of the command circuitry. Based on the first mode, method **500** may service the access request by sending (at **540**) an explicit PRE command and then sending (at **550**) an ACT command that is distinct from that explicit PRE command. However, if the number of ACT/iPRE commands currently pending at the memory device has a second relationship to the threshold number (e.g., less

than, or less than or equal to), then the mode selection circuitry may configure a second mode of the command circuitry. Based on the second mode, method **500** may service the access request by sending a consolidated ACT/iPRE command at **560**.

FIG. **6** is a timing diagram **600** illustrating features of activation and precharge command signaling according to an embodiment. In FIG. **6**, two distinct commands (PRE and ACT) are provided as signaling **610** between a memory controller and a memory device coupled thereto. These commands are also provided some time later as signaling **620** on a command link that is internal to the memory device. Signaling **610** may be exchanged in response to a determination that a current total number of consolidated ACT/iPRE commands pending at the memory device exceeds a threshold. Timing diagram shows illustrative examples of timing parameters tRP, tRRD that, but for a threshold value indicated to the memory controller, might otherwise be used by the memory controller to determine a maximum number of pending ACT/iPRE commands for the memory device.

FIG. **7** is a timing diagram illustrating the case in which a consolidated ACT/iPRE command is provided as signaling **710** on a link between a memory controller and a memory device, but distinct commands iPRE and ACT are provided in succession as signaling **720a** some time later on a command link that is internal to the memory device. The various timings on FIGS. **6** and **7** are merely illustrative and not necessary in all embodiments.

To illustrate a theoretical maximum number of pending ACT/iPRE commands, timing diagram **700a** is shown in relation to the timing of other signaling **720b**, . . . **720n** each for a respective hypothetical copending memory access request. In the example shown for timing diagram **700**, a theoretical maximum number of pending ACT/iPRE commands is shown as being determined by a total number of tRP periods that fit into a tRRD period of a pending consolidated ACT/iPRE command. In such an embodiment, a theoretical maximum Nmax may be represented, for example, by the following equation.

$$N_{max} = \left(1 + \left\lfloor \frac{tRRD}{tRP} \right\rfloor \right) \quad (1)$$

With respect to a given memory IC (or other memory device), certain embodiments variously set for a memory controller a maximum number of pending ACT/iPRE commands that is less than such a theoretical maximum Nmax.

FIG. **8** is a block diagram of an embodiment of a computing system in which memory accesses may be implemented. System **800** represents a computing device in accordance with any embodiment described herein, and may be a laptop computer, a desktop computer, a server, a gaming or entertainment control system, a scanner, copier, printer, or other electronic device. System **800** may include processor **820**, which provides processing, operation management, and execution of instructions for system **800**. Processor **820** may include any type of microprocessor, central processing unit (CPU), processing core, or other processing hardware to provide processing for system **800**. Processor **820** controls the overall operation of system **800**, and may be or include, one or more programmable general-purpose or special-purpose microprocessors, digital signal processors (DSPs), programmable controllers, application specific integrated

circuits (ASICs), programmable logic devices (PLDs), or the like, or a combination of such devices.

Memory subsystem **830** represents the main memory of system **800**, and provides temporary storage for code to be executed by processor **820**, or data values to be used in executing a routine. Memory subsystem **830** may include one or more memory devices such as read-only memory (ROM), flash memory, one or more varieties of random access memory (RAM), or other memory devices, or a combination of such devices. Memory subsystem **830** stores and hosts, among other things, operating system (OS) **836** to provide a software platform for execution of instructions in system **800**. Additionally, other instructions **838** are stored and executed from memory subsystem **830** to provide the logic and the processing of system **800**. OS **836** and instructions **838** are executed by processor **820**.

Memory subsystem **830** may include memory device **832** where it stores data, instructions, programs, or other items. In one embodiment, memory subsystem includes memory controller **834**, which is a memory controller in accordance with any embodiment described herein, and which provides mechanisms for accessing memory device **832**. In one embodiment, memory controller **834** provides commands to memory device **832**. The commands may cause memory device **832** to internally generate activate commands and/or precharge commands for memory resources.

Processor **820** and memory subsystem **830** are coupled to bus/bus system **810**. Bus **810** is an abstraction that represents any one or more separate physical buses, communication lines/interfaces, and/or point-to-point connections, connected by appropriate bridges, adapters, and/or controllers. Therefore, bus **810** may include, for example, one or more of a system bus, a Peripheral Component Interconnect (PCI) bus, a HyperTransport or industry standard architecture (ISA) bus, a small computer system interface (SCSI) bus, a universal serial bus (USB), or an Institute of Electrical and Electronics Engineers (IEEE) standard 1394 bus (commonly referred to as "Firewire"). The buses of bus **810** may also correspond to interfaces in network interface **850**.

System **800** may also include one or more input/output (I/O) interface(s) **840**, network interface **850**, one or more internal mass storage device(s) **860**, and peripheral interface **870** coupled to bus **810**. I/O interface **840** may include one or more interface components through which a user interacts with system **800** (e.g., video, audio, and/or alphanumeric interfacing). Network interface **850** provides system **800** the ability to communicate with remote devices (e.g., servers, other computing devices) over one or more networks. Network interface **850** may include an Ethernet adapter, wireless interconnection components, USB (universal serial bus), or other wired or wireless standards-based or proprietary interfaces.

Storage **860** may be or include any conventional medium for storing large amounts of data in a nonvolatile manner, such as one or more magnetic, solid state, or optical based disks, or a combination. Storage **860** holds code or instructions and data **862** in a persistent state (i.e., the value is retained despite interruption of power to system **800**). Storage **860** may be generically considered to be a "memory," although memory **830** is the executing or operating memory to provide instructions to processor **820**. Whereas storage **860** is nonvolatile, memory **830** may include volatile memory (i.e., the value or state of the data is indeterminate if power is interrupted to system **800**).

Peripheral interface **870** may include any hardware interface not specifically mentioned above. Peripherals refer generally to devices that connect dependently to system **800**.

A dependent connection is one where system **800** provides the software and/or hardware platform on which an operation executes, and with which a user interacts.

FIG. **9** is a block diagram of an embodiment of a mobile device in which memory accesses may be implemented. Device **900** represents a mobile computing device, such as a computing tablet, a mobile phone or smartphone, a wireless-enabled e-reader, or other mobile device. It will be understood that certain of the components are shown generally, and not all components of such a device are shown in device **900**.

Device **900** may include processor **910**, which performs the primary processing operations of device **900**. Processor **910** may include one or more physical devices, such as microprocessors, application processors, microcontrollers, programmable logic devices, or other processing means. The processing operations performed by processor **910** include the execution of an operating platform or operating system on which applications and/or device functions are executed. The processing operations include operations related to I/O (input/output) with a human user or with other devices, operations related to power management, and/or operations related to connecting device **900** to another device. The processing operations may also include operations related to audio I/O and/or display I/O.

In one embodiment, device **900** includes audio subsystem **920**, which represents hardware (e.g., audio hardware and audio circuits) and software (e.g., drivers, codecs) components associated with providing audio functions to the computing device. Audio functions may include speaker and/or headphone output, as well as microphone input. Devices for such functions may be integrated into device **900**, or connected to device **900**. In one embodiment, a user interacts with device **900** by providing audio commands that are received and processed by processor **910**.

Display subsystem **930** represents hardware (e.g., display devices) and software (e.g., drivers) components that provide a visual and/or tactile display for a user to interact with the computing device. Display subsystem **930** may include display interface **932**, which may include the particular screen or hardware device used to provide a display to a user. In one embodiment, display interface **932** includes logic separate from processor **910** to perform at least some processing related to the display. In one embodiment, display subsystem **930** includes a touchscreen device that provides both output and input to a user.

I/O controller **940** represents hardware devices and software components related to interaction with a user. I/O controller **940** may operate to manage hardware that is part of audio subsystem **920** and/or display subsystem **930**. Additionally, I/O controller **940** illustrates a connection point for additional devices that connect to device **900** through which a user might interact with the system. For example, devices that may be attached to device **900** might include microphone devices, speaker or stereo systems, video systems or other display device, keyboard or keypad devices, or other I/O devices for use with specific applications such as card readers or other devices.

As mentioned above, I/O controller **940** may interact with audio subsystem **920** and/or display subsystem **930**. For example, input through a microphone or other audio device may provide input or commands for one or more applications or functions of device **900**. Additionally, audio output may be provided instead of or in addition to display output. In another example, if display subsystem includes a touchscreen, the display device also acts as an input device, which may be at least partially managed by I/O controller **940**.

There may also be additional buttons or switches on device **900** to provide I/O functions managed by I/O controller **940**.

In one embodiment, I/O controller **940** manages devices such as accelerometers, cameras, light sensors or other environmental sensors, gyroscopes, global positioning system (GPS), or other hardware that may be included in device **900**. The input may be part of direct user interaction, as well as providing environmental input to the system to influence its operations (such as filtering for noise, adjusting displays for brightness detection, applying a flash for a camera, or other features).

In one embodiment, device **900** includes power management **950** that manages battery power usage, charging of the battery, and features related to power saving operation. Memory subsystem **960** may include memory device(s) **962** for storing information in device **900**. Memory subsystem **960** may include nonvolatile (state does not change if power to the memory device is interrupted) and/or volatile (state is indeterminate if power to the memory device is interrupted) memory devices. Memory **960** may store application data, user data, music, photos, documents, or other data, as well as system data (whether long-term or temporary) related to the execution of the applications and functions of system **900**.

In one embodiment, memory subsystem **960** includes memory controller **964** (which could also be considered part of the control of system **900**, and could potentially be considered part of processor **910**). Memory controller **964** monitors voltage swing characteristics of a bus. For example, memory controller **964** may detect different voltage swing characteristics for different signal lines of the same bus—e.g. a data bus. In an embodiment, memory controller **964** issues commands which cause memory **962** to internally generate an activate command or a precharge command for memory resources.

Connectivity **970** may include hardware devices (e.g., wireless and/or wired connectors and communication hardware) and software components (e.g., drivers, protocol stacks) to enable device **900** to communicate with external devices. The device could be separate devices, such as other computing devices, wireless access points or base stations, as well as peripherals such as headsets, printers, or other devices.

Connectivity **970** may include multiple different types of connectivity. To generalize, device **900** is illustrated with cellular connectivity **972** and wireless connectivity **974**. Cellular connectivity **972** refers generally to cellular network connectivity provided by wireless carriers, such as provided via GSM (global system for mobile communications) or variations or derivatives, CDMA (code division multiple access) or variations or derivatives, TDM (time division multiplexing) or variations or derivatives, LTE (long term evolution—also referred to as “4G”), or other cellular service standards. Wireless connectivity **974** refers to wireless connectivity that is not cellular, and may include personal area networks (such as Bluetooth), local area networks (such as WiFi), and/or wide area networks (such as WiMax), or other wireless communication. Wireless communication refers to transfer of data through the use of modulated electromagnetic radiation through a non-solid medium. Wired communication occurs through a solid communication medium.

Peripheral connections **980** include hardware interfaces and connectors, as well as software components (e.g., drivers, protocol stacks) to make peripheral connections. It will be understood that device **900** could both be a peripheral device (“to” **982**) to other computing devices, as well as

have peripheral devices (“from” **984**) connected to it. Device **900** commonly has a “docking” connector to connect to other computing devices for purposes such as managing (e.g., downloading and/or uploading, changing, synchronizing) content on device **900**. Additionally, a docking connector may allow device **900** to connect to certain peripherals that allow device **900** to control content output, for example, to audiovisual or other systems.

In addition to a proprietary docking connector or other proprietary connection hardware, device **900** may make peripheral connections **980** via common or standards-based connectors. Common types may include a Universal Serial Bus (USB) connector (which may include any of a number of different hardware interfaces), DisplayPort including MiniDisplayPort (MDP), High Definition Multimedia Interface (HDMI), Firewire, or other type.

In one implementation, a memory device comprises one or more arrays of memory cells, an input/output interface to detect connectivity of the memory device to a memory controller, and threshold identification logic to send to the memory controller information indicating a threshold number of pending consolidated activation commands to access the one or more arrays of memory cells, wherein a consolidated activation command indicates a precharge command, wherein the threshold number is less than a theoretical maximum number of pending consolidated activation commands, wherein the theoretical maximum number is based on timing parameters of the memory device, and wherein the memory controller limits communication of consolidated activation commands to the memory device based on the information indicating the threshold number.

In an embodiment, the theoretical maximum number is based on a timing parameter tRP representing a minimum time necessary to perform a memory precharge operation, and a timing parameter tRRD representing a minimum time necessary between successive activation operations. In another embodiment, the theoretical maximum number is equal to a sum of one and an integer equal to a floor function value based on a ratio of tRRD to tRP. In another embodiment, the threshold number is greater than one. In another embodiment, the information indicating the threshold number of pending consolidated activation commands includes the threshold number of pending consolidated activation commands. In another embodiment, wherein the information indicating the threshold number of pending consolidated activation commands includes a product identifier number, wherein the memory controller accesses reference data based on the product identification number to determine the threshold number of pending consolidated activation commands.

In another implementation, a memory controller comprises an input/output interface to couple the memory controller to a memory device, and mode selection circuitry to receive information indicating a threshold number of pending consolidated activation commands to access the memory device, wherein a consolidated activation command indicates a precharge command, wherein the threshold number is less than a theoretical maximum number of pending consolidated activation commands, wherein the theoretical maximum number is based on timing parameters of the memory device. The memory controller further comprises command logic to communicate consolidated activation commands to the memory device, wherein the mode selection logic to limit communication of consolidated activation commands to the memory device based on the information indicating the threshold number.

15

In an embodiment, the theoretical maximum number is based on a timing parameter tRP representing a minimum time necessary to perform a memory precharge operation, and a timing parameter tRRD representing a minimum time necessary between successive activation operations. In another embodiment, the theoretical maximum number is equal to a sum of one and an integer equal to a floor function value based on a ratio of tRRD to tRP. In another embodiment, the threshold number is greater than one. In another embodiment, the information indicating the threshold number of pending consolidated activation commands includes the threshold number of pending consolidated activation commands. In another embodiment, the information indicating the threshold number of pending consolidated activation commands includes a product identifier number, wherein the memory controller accesses reference data based on the product identification number to determine the threshold number of pending consolidated activation commands.

In another implementation, a method at a memory device comprises detecting connectivity of the memory device to a memory controller, and in response to detecting the connectivity, sending to the memory controller information indicating a threshold number of pending consolidated activation commands to access the memory device, wherein a consolidated activation command indicates a precharge command, wherein the threshold number is less than a theoretical maximum number of pending consolidated activation commands, the theoretical maximum number based on timing parameters of the memory device, wherein the memory controller limits communication of consolidated activation commands to the memory device based on the information indicating the threshold number.

In an embodiment, the theoretical maximum number is based on a timing parameter tRP representing a minimum time necessary to perform a memory precharge operation, and a timing parameter tRRD representing a minimum time necessary between successive activation operations. In another embodiment, wherein the theoretical maximum number is equal to a sum of one and an integer equal to a floor function value based on a ratio of tRRD to tRP. In another embodiment, the threshold number is greater than one. In another embodiment, the information indicating the threshold number of pending consolidated activation commands includes the threshold number of pending consolidated activation commands. In another embodiment, the information indicating the threshold number of pending consolidated activation commands includes a product identifier number, wherein the memory controller accesses reference data based on the product identification number to determine the threshold number of pending consolidated activation commands.

In another implementation, a method at a memory controller comprises receiving information indicating a threshold number of pending consolidated activation commands to access a memory device coupled to the memory controller, wherein a consolidated activation command indicates a precharge command, wherein the threshold number is less than a theoretical maximum number of pending consolidated activation commands, wherein the theoretical maximum number is based on timing parameters of the memory device, and limiting a communication of consolidated activation commands to the memory device based on the information indicating the threshold number.

In an embodiment, the theoretical maximum number is based on a timing parameter tRP representing a minimum time necessary to perform a memory precharge operation,

16

and a timing parameter tRRD representing a minimum time necessary between successive activation operations. In another embodiment, the theoretical maximum number is equal to a sum of one and an integer equal to a floor function value based on a ratio of tRRD to tRP. In another embodiment, the threshold number is greater than one. In another embodiment, the information indicating the threshold number of pending consolidated activation commands includes the threshold number of pending consolidated activation commands. In another embodiment, the information indicating the threshold number of pending consolidated activation commands includes a product identifier number, wherein the memory controller accesses reference data based on the product identification number to determine the threshold number of pending consolidated activation commands.

In another implementation, a computer-readable storage medium has stored thereon instructions which, when executed by one or more processing units, cause a memory controller to perform a method comprising receiving information indicating a threshold number of pending consolidated activation commands to access a memory device coupled to the memory controller, wherein a consolidated activation command indicates a precharge command, wherein the threshold number is less than a theoretical maximum number of pending consolidated activation commands, wherein the theoretical maximum number is based on timing parameters of the memory device, and limiting a communication of consolidated activation commands to the memory device based on the information indicating the threshold number.

In an embodiment, the theoretical maximum number is based on a timing parameter tRP representing a minimum time necessary to perform a memory precharge operation, and a timing parameter tRRD representing a minimum time necessary between successive activation operations. In another embodiment, the theoretical maximum number is equal to a sum of one and an integer equal to a floor function value based on a ratio of tRRD to tRP. In another embodiment, the threshold number is greater than one. In another embodiment, the information indicating the threshold number of pending consolidated activation commands includes the threshold number of pending consolidated activation commands. In another embodiment, the information indicating the threshold number of pending consolidated activation commands includes a product identifier number, wherein the memory controller accesses reference data based on the product identification number to determine the threshold number of pending consolidated activation commands.

Techniques and architectures for accessing memory resources are described herein. In the above description, for purposes of explanation, numerous specific details are set forth in order to provide a thorough understanding of certain embodiments. It will be apparent, however, to one skilled in the art that certain embodiments can be practiced without these specific details. In other instances, structures and devices are shown in block diagram form in order to avoid obscuring the description.

Reference in the specification to “one embodiment” or “an embodiment” means that a particular feature, structure, or characteristic described in connection with the embodiment is included in at least one embodiment of the invention. The appearances of the phrase “in one embodiment” in various places in the specification are not necessarily all referring to the same embodiment.

Some portions of the detailed description herein are presented in terms of algorithms and symbolic representations of operations on data bits within a computer memory. These algorithmic descriptions and representations are the means used by those skilled in the computing arts to most effectively convey the substance of their work to others skilled in the art. An algorithm is here, and generally, conceived to be a self-consistent sequence of steps leading to a desired result. The steps are those requiring physical manipulations of physical quantities. Usually, though not necessarily, these quantities take the form of electrical or magnetic signals capable of being stored, transferred, combined, compared, and otherwise manipulated. It has proven convenient at times, principally for reasons of common usage, to refer to these signals as bits, values, elements, symbols, characters, terms, numbers, or the like.

It should be borne in mind, however, that all of these and similar terms are to be associated with the appropriate physical quantities and are merely convenient labels applied to these quantities. Unless specifically stated otherwise as apparent from the discussion herein, it is appreciated that throughout the description, discussions utilizing terms such as “processing” or “computing” or “calculating” or “determining” or “displaying” or the like, refer to the action and processes of a computer system, or similar electronic computing device, that manipulates and transforms data represented as physical (electronic) quantities within the computer system’s registers and memories into other data similarly represented as physical quantities within the computer system memories or registers or other such information storage, transmission or display devices.

Certain embodiments also relate to apparatus for performing the operations herein. This apparatus may be specially constructed for the required purposes, or it may comprise a general purpose computer selectively activated or reconfigured by a computer program stored in the computer. Such a computer program may be stored in a computer readable storage medium, such as, but is not limited to, any type of disk including floppy disks, optical disks, CD-ROMs, and magnetic-optical disks, read-only memories (ROMs), random access memories (RAMs) such as dynamic RAM (DRAM), EPROMs, EEPROMs, magnetic or optical cards, or any type of media suitable for storing electronic instructions, and coupled to a computer system bus.

The algorithms and displays presented herein are not inherently related to any particular computer or other apparatus. Various general purpose systems may be used with programs in accordance with the teachings herein, or it may prove convenient to construct more specialized apparatus to perform the required method steps. The required structure for a variety of these systems will appear from the description herein. In addition, certain embodiments are not described with reference to any particular programming language. It will be appreciated that a variety of programming languages may be used to implement the teachings of such embodiments as described herein.

Besides what is described herein, various modifications may be made to the disclosed embodiments and implementations thereof without departing from their scope. Therefore, the illustrations and examples herein should be construed in an illustrative, and not a restrictive sense. The scope of the invention should be measured solely by reference to the claims that follow.

What is claimed is:

1. A memory device comprising:
one or more arrays of memory cells;

an input/output interface to detect connectivity of the memory device to a memory controller; and
threshold identification logic to send to the memory controller information indicating a threshold number of pending consolidated activation commands to access the one or more arrays of memory cells, wherein a consolidated activation command indicates a precharge command, wherein the threshold number is less than a theoretical maximum number of pending consolidated activation commands, wherein the theoretical maximum number is based on timing parameters of the memory device, and wherein the memory controller limits communication of consolidated activation commands to the memory device based on the information indicating the threshold number.

2. The memory device of claim 1, wherein the theoretical maximum number is based on:

a timing parameter tRP representing a minimum time necessary to perform a memory precharge operation; and

a timing parameter tRRD representing a minimum time necessary between successive activation operations.

3. The memory device of claim 2, wherein the theoretical maximum number is equal to a sum of one and an integer equal to a floor function value based on a ratio of tRRD to tRP.

4. The memory device of claim 1, wherein the threshold number is greater than one.

5. The memory device of claim 1, wherein the information indicating the threshold number of pending consolidated activation commands includes the threshold number of pending consolidated activation commands.

6. The memory device of claim 1, wherein the information indicating the threshold number of pending consolidated activation commands includes a product identifier number, wherein the memory controller accesses reference data based on the product identification number to determine the threshold number of pending consolidated activation commands.

7. A memory controller comprising:

an input/output interface to couple the memory controller to a memory device;

mode selection circuitry to receive information indicating a threshold number of pending consolidated activation commands to access the memory device, wherein a consolidated activation command indicates a precharge command, wherein the threshold number is less than a theoretical maximum number of pending consolidated activation commands, wherein the theoretical maximum number is based on timing parameters of the memory device; and

command logic to communicate consolidated activation commands to the memory device, wherein the mode selection logic to limit communication of consolidated activation commands to the memory device based on the information indicating the threshold number.

8. The memory controller of claim 7, wherein the theoretical maximum number is based on:

a timing parameter tRP representing a minimum time necessary to perform a memory precharge operation; and

a timing parameter tRRD representing a minimum time necessary between successive activation operations.

9. The memory controller of claim 8, wherein the theoretical maximum number is equal to a sum of one and an integer equal to a floor function value based on a ratio of tRRD to tRP.

19

10. The memory controller of claim 7, wherein the threshold number is greater than one.

11. The memory controller of claim 7, wherein the information indicating the threshold number of pending consolidated activation commands includes a product identifier number, wherein the memory controller accesses reference data based on the product identification number to determine the threshold number of pending consolidated activation commands.

12. A method at a memory device, the method comprising:

detecting connectivity of the memory device to a memory controller; and

in response to detecting the connectivity, sending to the memory controller information indicating a threshold number of pending consolidated activation commands to access the memory device, wherein a consolidated activation command indicates a precharge command, wherein the threshold number is less than a theoretical maximum number of pending consolidated activation commands, the theoretical maximum number based on timing parameters of the memory device, wherein the memory controller limits communication of consolidated activation commands to the memory device based on the information indicating the threshold number.

13. The method of claim 12, wherein the theoretical maximum number is based on:

a timing parameter tRP representing a minimum time necessary to perform a memory precharge operation; and

a timing parameter tRRD representing a minimum time necessary between successive activation operations.

14. The method of claim 13, wherein the theoretical maximum number is equal to a sum of one and an integer equal to a floor function value based on a ratio of tRRD to tRP.

15. The method of claim 12, wherein the information indicating the threshold number of pending consolidated activation commands includes a product identifier number, wherein the memory controller accesses reference data based on the product identification number to determine the threshold number of pending consolidated activation commands.

16. A method at a memory controller, the method comprising:

receiving information indicating a threshold number of pending consolidated activation commands to access a memory device coupled to the memory controller, wherein a consolidated activation command indicates a precharge command, wherein the threshold number is less than a theoretical maximum number of pending consolidated activation commands, wherein the theoretical maximum number is based on timing parameters of the memory device; and

limiting a communication of consolidated activation commands to the memory device based on the information indicating the threshold number.

17. The method of claim 16, wherein the theoretical maximum number is based on:

a timing parameter tRP representing a minimum time necessary to perform a memory precharge operation; and

20

a timing parameter tRRD representing a minimum time necessary between successive activation operations.

18. The method of claim 17, wherein the theoretical maximum number is equal to a sum of one and an integer equal to a floor function value based on a ratio of tRRD to tRP.

19. The method of claim 16, wherein the information indicating the threshold number of pending consolidated activation commands includes a product identifier number, wherein the memory controller accesses reference data based on the product identification number to determine the threshold number of pending consolidated activation commands.

20. A system comprising:

a memory controller;

a memory device including:

one or more arrays of memory cells;

an input/output interface coupled to the memory controller; and

threshold identification logic to send to the memory controller information indicating a threshold number of pending consolidated activation commands to access the one or more arrays of memory cells, wherein a consolidated activation command indicates a precharge command, wherein the threshold number is less than a theoretical maximum number of pending consolidated activation commands, wherein the theoretical maximum number is based on timing parameters of the memory device, and wherein the memory controller limits communication of consolidated activation commands to the memory device based on the information indicating the threshold number; and

a display coupled to the memory controller and the memory.

21. The system of claim 20, wherein the theoretical maximum number is based on:

a timing parameter tRP representing a minimum time necessary to perform a memory precharge operation; and

a timing parameter tRRD representing a minimum time necessary between successive activation operations.

22. The system of claim 21, wherein the theoretical maximum number is equal to a sum of one and an integer equal to a floor function value based on a ratio of tRRD to tRP.

23. The system of claim 20, wherein the threshold number is greater than one.

24. The system of claim 20, wherein the information indicating the threshold number of pending consolidated activation commands includes the threshold number of pending consolidated activation commands.

25. The system of claim 20, wherein the information indicating the threshold number of pending consolidated activation commands includes a product identifier number, wherein the memory controller accesses reference data based on the product identification number to determine the threshold number of pending consolidated activation commands.
