P. H. ALLISON.

COMBINATION CENTER SQUARE.

APPLICATION FILED JAN. 2, 1909.

934,260.

Patented Sept. 14, 1909.

UNITED STATES PATENT OFFICE.

PETER HALL ALLISON, OF TORRINGTON, CONNECTICUT.

COMBINATION CENTER-SQUARE.

934,260.

Patented Sept. 14, 1909. Specification of Letters Patent.

Application filed January 2, 1909. Serial No. 470,396.

To all whom it may concern:
Be it known that I, Peter Hall Allison, a subject of the King of Great Britain, and a resident of Torrington, in the county of 5 Litchfield and State of Connecticut, have invented a new and Improved Combination Center-Square, of which the following is a full, clear, and exact description.

The invention relates to measuring instru-10 ments, and its object is to provide a new and improved combination center square, more especially designed for accurately determining the center of round work, for laying out angles and for use as a T-square, depth-

15 gage and scale.

For the purpose mentioned the instrument is provided with a blade and a head thereon, having apertures disposed on opposite sides of a line coinciding with the inner edge of 20 the blade, and removable pins for engagement with the said apertures to bring the pins and the edge of the blade in desired relative positions.

A practical embodiment of the invention 25 is represented in the accompanying drawings forming a part of this specification, in which similar characters of reference indi-

cate corresponding parts in all the views. Figure 1 is a perspective view of the im-30 provement; Fig. 2 is a plan view of the same, parts being in section, and showing the in-strument as applied for centering a round piece of work; Fig. 3 is a cross section of the same on the line 3—3 of Fig. 2 and showing the instrument applied to a piece of work of small diameter; and Fig. 4 is a plan view of the improvement and showing the various angles that can be accurately laid out by the use of the instrument.

The blade A of the measuring instrument terminates at one end in a head B extending on opposite sides of the inner edge A' of the blade A, as plainly shown in the drawings. The head B is provided with pairs of apertures C, C' and C², C³, of which the apertures C, C' are disposed equidistant on opposite sides of a line coinciding with the inner edge A', and the apertures C2, C3 are similarly disposed equidistant on opposite 50 sides of the inner edge A', but the apertures C, C' are nearer together than the apertures C², C³. An auxiliary aperture C⁴ is also arranged on the head B a distance forward of the aperture C². The apertures 55 C, C' are adapted to be engaged by removable head pins D, D', and similar pins D2, D3

are adapted to be engaged with the apertures C2, C3, and any one of the pins may be in-

serted in the aperture C4.

Now when it is desired to find the center 60 of a round piece of work E of large diameter, as shown in Fig. 2, then use is made of the two pins D², D³, and the instrument is applied to the work E, so that the pins D³ and applied to the morphoral face of the D^2 , D^3 engage the peripheral face of the 65 work E and the blade A extends across the end to be centered. Now lines are drawn along the edge A' across the end of the work E, and the intersection of the lines indicates the center of the work E.

When it is desired to find the center of a small piece of work E' use is made of the pins D, D' in the same manner as above described relative to the work E and the pins

By using the pins D, D³, for instance, while the other pins D', D² are removed, an angle of 45° may be drawn relative to the edge against which the said pins D and D³ abut, and angles of 60° and 30° may be 80 drawn by inserting the pin D² in the aperture C⁴ and using this pin D² in connection with the pin D' inserted in the aperture C'. In a like manner an angle of 60° may be drawn by the use of pins in the apertures 85 C³ and C⁴, it being understood that the angles are drawn along the inner edge A' of the blade A.

It will be understood that the arrangement of the apertures C, C', C² and C³ with 90 respect to the edge A' is such that a line drawn through the centers of the openings C, C3 will form upon the side adjacent to the opening C3 an angle of 45° with the edge, while on the opposite side the angle 95 will be 135°. The arrangement of the openings C', C² with respect to the edge is the same. The arrangement of the opening C and the opening C' with respect to the edge is graph that a line drawn through the conis such that a line drawn through the cen- 100 ters of C', C4 will make an angle of 30° with the edge on the side toward the opening C⁴, while a line drawn through the centers of C3, C4 will make an angle of 60° with the edge upon the side toward the opening C⁴. 105 It is also understood that by the use of the pins D, D' engaging the apertures C, C' or the pins D², D³ engaging the apertures C², C³ the instrument can be used as a T square C³, the instrument can be used as a T-square or as a depth gage, the edge A' being for the 110 purpose provided with a graduation representing linear measurement.

The measuring instrument shown and described is very simple and durable in construction, and by the use of the removable pins in the several apertures the instrument can be readily used for accurately determining the center of round work, for laying out angles and for using the instrument as a

square, depth gage, scale and the like.
The lines shown in Fig. 4, extending out10 side of the instrument and marked 45, are lines that may be laid out by the instrument relative to an arbitrary line which may be

considered as the base.

Having thus described my invention, I 15 claim as new and desire to secure by Letters Patent:

1. A measuring instrument comprising a head and a blade having a straight edge and extending from the head, said head having 20 detachable pins connected therewith and arranged in pairs, the members of each pair being arranged upon opposite sides of the straight edge of the blade and at equal distances therefrom, and in such manner that 25 the lines connecting the centers of the members of a pair will intersect the edge at a right angle.

2. A measuring instrument comprising a blade, a head on one end of the said blade 30 and having pairs of apertures, the apertures of each pair being spaced equidistant on opposite sides of a line coinciding with the inner edge of the said blade, and pins for removable engagement with the said aper-

35 tures.

3. A measuring instrument comprising a

blade, a head on one end of the said blade and having pairs of apertures, the apertures of each pair being spaced equidistant on opposite sides of a line coinciding with the inner edge of the said blade, the distances between the apertures of the said pairs of apertures varying for larger and smaller work, and pins for removable engagement with the said apertures.

4. A measuring instrument comprising a blade, a head on one end of the said blade and having pairs of apertures, the apertures of each pair being spaced equidistant on opposite sides of a line coinciding with the 5 inner edge of the said blade, the said head also having an auxiliary aperture, and pins for removable engagement with the said

apertures.

5. A measuring instrument comprising a 5 head and a blade having a straight edge and extending from the head, the head having a series of openings upon each side of the straight edge, the individual members of which are arranged at different distances of the page the arranged at different distances of the page that from the edge, the arrangement of the members of the series on one side being symmetrical with the arrangement of the series of the members on the other side, and a pair

of pins for engaging the openings.

In testimony whereof I have signed my name to this specification in the presence of

two subscribing witnesses.

PETER HALL ALLISON.

Witnesses:

EDWARD W. MORGAN, Daniel McDougall.
