Dihydropyrimidines and Uses Thereof

Throughout this application, various references are referred to within parentheses. Disclosures of these publications in their entireties are hereby incorporated by reference into this application to more fully describe the state of the art to which this invention pertains.

Background of the Invention

The designation "α_{IA}" is the appellation recently approved by the IUPHAR Nomenclature Committee for the previously designated "α_{IC}" cloned subtype as outlined in the 1995 Receptor and Ion Channel Nomenclature Supplement (Watson and Girdlestone, 1995). The designation α_{IA} is used throughout this application and the supporting tables and figures to refer to this receptor subtype. At the same time, the receptor formerly designated α_{IA} was renamed α_{ID}. The new nomenclature is used throughout this application. Stable cell lines expressing these receptors are described herein; however, these cell lines were deposited with the American Type Culture Collection (ATCC) under the old nomenclature (infra).

Benign Prostatic Hyperplasia (BPH), also called Benign Prostatic Hypertrophy, is a progressive condition which is characterized by a nodular enlargement of prostatic tissue resulting in obstruction of the urethra. This results in increased frequency of urination, nocturia, a poor urine stream and hesitancy or delay in starting the urine flow. Chronic consequences of BPH can
include hypertrophy of bladder smooth muscle, a
decompensated bladder and an increased incidence of
urinary tract infection. The specific biochemical,
histological and pharmacological properties of the
prostate adenoma leading to the bladder outlet
obstruction are not yet known. However, the
development of BPH is considered to be an inescapable
phenomenon for the aging male population. BPH is
observed in approximately 70% of males over the age of
70. Currently, in the United States, the method of
choice for treating BPH is surgery (Lepor, H., Urol.
Clinics North Amer., 17, 651 (1990)). Over 400,000
prostatectomies are performed annually (data from
1986). A medicinal alternative to surgery is clearly
very desirable. The limitations of surgery for
treating BPH include the morbidity rate of an operative
procedure in elderly men, persistence or recurrence of
obstructive and irritative symptoms, as well as the
significant cost of surgery.

Rev., 9, 407-533, 1989) are specific neuroreceptor
proteins located in the peripheral and central nervous
systems on tissues and organs throughout the body.
These receptors are important switches for controlling
many physiological functions and, thus, represent
important targets for drug development. In fact, many
α-adrenergic drugs have been developed over the past 40
years. Examples include clonidine, phenoxybenzamine
and prazosin (treatment of hypertension), naphazoline
(nasal decongestant), and apraclonidine (treating
glaucoma). α-Adrenergic drugs can be broken down into
two distinct classes: agonists (clonidine and
naphazoline are agonists), which mimic the receptor
activation properties of the endogenous
neurotransmitter norepinephrine, and antagonists
(phenoxybenzamine and prazosin are antagonists), which
act to block the effects of norepinephrine. Many of
these drugs are effective but also produce unwanted
side effects (for example, clonidine produces dry mouth and sedation in addition to its antihypertensive effects).

During the past 15 years a more precise understanding of $\alpha$-adrenergic receptors and their drugs has evolved through increased scientific scrutiny. Prior to 1977, only one $\alpha$-adrenergic receptor was known to exist. Between 1977 and 1988, it was accepted by the scientific community that at least two $\alpha$-adrenergic receptors---$\alpha_1$ and $\alpha_2$---existed in the central and peripheral nervous systems. Since 1988, new techniques in molecular biology have led to the identification of at least six $\alpha$-adrenergic receptors which exist throughout the central and peripheral nervous systems: $\alpha_{1A}$ (new nomenclature), $\alpha_{1B}$, $\alpha_{1D}$ (new nomenclature), $\alpha_{2A}$, $\alpha_{2B}$ and $\alpha_{2C}$ (Bylund, D.B., FASEB J., 6, 832 (1992)). In many cases, it is not known precisely which physiological responses in the body are controlled by each of these receptors. In addition, current $\alpha$-adrenergic drugs are not selective for any particular $\alpha$-adrenergic receptor. Many of these drugs produce untoward side effects which may be attributed to their poor $\alpha$-adrenergic receptor selectivity.

Since the mid 1970's, nonselective $\alpha$-antagonists have been prescribed to treat BPH. In 1976, M. Caine, et al. (Brit. J. Urol., 48, 255 (1976)), reported that the nonselective $\alpha$-antagonist phenoxybenzamine was useful in relieving the symptoms of BPH. This drug may produce its effects by interacting with $\alpha$-receptors located on the prostate. However, this drug also produces significant side effects such as dizziness and asthenia which severely limit its use in treating patients on a chronic basis. More recently, the $\alpha$-adrenergic antagonists prazosin and terazosin have also been found to be useful for treating BPH.
However, these drugs also produce untoward side effects. It has recently been discovered that the α_{1A} receptor is responsible for mediating the contraction of human prostate smooth muscle (Gluchowski, C. et al., WO 94/10989, 1994; Forray, C. et al., Mol. Pharmacol. 45, 703, 1994). This discovery indicates that the α_{1A} antagonists may be effective agents for the treatment of BPH with decreased side effects. Further studies have indicated that the α_{1A} receptor may also be present in other lower urinary tract tissues, such as urethral smooth muscle (Ford et al. Br. J. Pharmacol., 114, 24P, (1995)).

This invention is directed to dihydropyrimidine compounds which are selective antagonists for cloned human α_{1A} receptors. This invention is also related to uses of these compounds for lowering intraocular pressure (Zhan, et al. Ophthal mol. Vis. Sci., 34 Abst. #1133, 928, 1993), inhibiting cholesterol synthesis (D'Eletto and Javitt, J. Cardiovascular Pharmacol., 13 (Suppl. 2) S1-S4, 1989), benign prostatic hyperplasia, impotency (Milne and Wyllie, EP 0 459 666 A2, 1991), sympathetically mediated pain (Campbell, WO 92/14453, 1992), cardiac arrhythmia (Spiers, et al., J. Cardiovascular Pharmacol., 16, 824-830, 1990) and for the treatment of any disease where antagonism of the α_{1A} receptor may be useful.
Summary of the Invention

This invention is directed to dihydropyrimidine compounds which are selective antagonists for human $\alpha_{1A}$ receptors. This invention is also related to uses of these compounds for lowering intraocular pressure, inhibiting cholesterol synthesis, relaxing lower urinary tract tissue, the treatment of benign prostatic hyperplasia, impotency, cardiac arrhythmia and for the treatment of any disease where antagonism of the $\alpha_{1A}$ receptor may be useful. The invention further provides a pharmaceutical composition comprising a therapeutically effective amount of the above-defined compounds and a pharmaceutically acceptable carrier.

Pharmacological Profiles of the Compounds in Cloned Human Adrenergic Receptors.

Binding affinities were measured for selected compounds of the invention at six cloned human alpha-1 and alpha-2 receptor subtypes, as well as at the L-type calcium channel. The protocols for these experiments are given below.

Protocol for the Determination of the Potency of $\alpha_1$ Antagonists

The activity of compounds at the different human receptors was determined in vitro using cultured cell lines that selectively express the receptor of interest. These cell lines were prepared by transfecting the cloned cDNA or cloned genomic DNA or constructs containing both genomic DNA and cDNA encoding the human $\alpha_1$-adrenergic receptors as follows:

$\alpha_1D$ Human Adrenergic Receptor: The entire coding region of $\alpha_1D$ (1719 bp), including 150 base pairs of 5' untranslated sequence (5' UT) and 300 bp of 3' untranslated sequence (3' UT), was cloned into the BamHI and ClaI sites of the polylinker-modified eukaryotic expression vector pCEXV-3, called EXJ.HR. The construct involved the ligation of partial overlapping human lymphocyte genomic and hippocampal cDNA clones: 5' sequence were contained on a 1.2 kb SmaI-XhoI genomic fragment (the vector-derived BamHI site was used for subcloning instead of the internal insert-derived SmaI site) and 3' sequences were contained on an 1.3 kb XhoI-ClaI cDNA fragment (the ClaI site was from the vector polylinker). Stable cell lines were obtained by cotransfection with the plasmid $\alpha_1A$/EXJ (expression vector containing the $\alpha_1A$ receptor gene (old nomenclature)) and the plasmid pGCCcos3neo (plasmid containing the aminoglycoside transferase
gene) into LM(tk-) cells using calcium phosphate technique. The cells were grown, in a controlled environment (37°C, 5% CO₂), as monolayers in Dulbecco’s modified Eagle’s Medium (GIBCO, Grand Island, NY) containing 25mM glucose and supplemented with 10% bovine calf serum, 100 units/ml penicillin g, and 100 μg/ml streptomycin sulfate. Stable clones were then selected for resistance to the antibiotic G-418 (1 mg/ml), and membranes were harvested and assayed for their ability to bind [³H]prazosin as described below (see "Radioligand Binding assays").

The cell line expressing the human α₁d receptor used herein was designated L-α₁d (old nomenclature) and was deposited with the American Type Culture Collection, 12301 Parklawn Drive, Rockville, Maryland 20852, U.S.A. under the provisions of the Budapest Treaty for the International Recognition of the Deposit of Microorganisms for the Purposes of Patent Procedure. The cell line expressing the human α₁d receptor, was accorded ATCC Accession No. CRL 11138, and was deposited on September 25, 1992.

α₁h Human Adrenergic Receptor: The entire coding region of α₁B (1563 bp), including 200 base pairs and 5’ untranslated sequence (5’ UT) and 600 bp of 3’ untranslated sequence (3’ UT), was cloned into the EcoRI site of pCEXV-3 eukaryotic expression vector. The construct involved ligating the full-length containing EcoRI brainstem cDNA fragment from λ ZapII into the expression vector. Stable cell lines were selected as described above. The cell line used herein was designated L-α₁h and was deposited with the American Type Culture Collection, 12301 Parklawn Drive, Rockville, Maryland 20852, U.S.A. under the provisions of the Budapest Treaty for the International Recognition of the Deposit of Microorganisms for the
Purposes of Patent Procedure. The cell line L-α_{1A} was accorded ATCC Accession No. CR 11139, on September 29, 1992.

**α_{1A} Human Adrenergic Receptor:** The entire coding region of α_{1A} (1401 bp), including 400 base pairs of 5' untranslated sequence (5' UT) and 200 bp of 3' untranslated sequence (3' UT), was cloned into the KpnI site of the polylinker-modified pCEXV-3-derived eukaryotic expression vector, EXJ.RH. The construct involved ligating three partial overlapping fragments: a 5' 0.6kb HincII genomic clone, a central 1.8 EcoRI hippocampal cDNA clone, and a 3' 0.6Kb PstI genomic clone. The hippocampal cDNA fragment overlaps with the 5' and 3' genomic clones so that the HincII and PstI sites at the 5' and 3' ends of the cDNA clone, respectively, were utilized for ligation. This full-length clone was cloned into the KpnI site of the expression vector, using the 5' and 3' KpnI sites of the fragment, derived from vector (i.e., pBluescript) and 3'-untranslated sequences, respectively. Stable cell lines were selected as described above. The stable cell line expressing the human α_{1A} receptor used herein was designated L-α_{1C} (old nomenclature) and was deposited with the American Type Culture Collection, 12301 Parklawn Drive, Rockville, Maryland 20852, U.S.A. under the provisions of the Budapest Treaty for the International Recognition of the Deposit of Microorganisms for the Purposes of Patent Procedure. The cell line expressing the human α_{1A} receptor was accorded Accession No. CR 11140, on September 25, 1992.

**Radioligand Binding Assays:** Transfected cells from culture flasks were scraped into 5ml of 5mM Tris-HCl, 5mM EDTA, pH 7.5, and lysed by sonication. The cell lysates were centrifuged at 1000 rpm for 5 min at 4°C, and the supernatant was centrifuged at 30,000 x g for
20 min at 4°C. The pellet was suspended in 50mM Tris-HCl, 1mM MgCl₂, and 0.1% ascorbic acid at pH 7.5. Binding of the α₁ antagonist [³H]prazosin (0.5 nM, specific activity 76.2 Ci/mmol) to membrane preparations of LM(tk⁻) cells was done in a final volume of 0.25 ml and incubated at 37°C for 20 min. Nonspecific binding was determined in the presence of 10 μM phentolamine. The reaction was stopped by filtration through GF/B filters using a cell harvester. Inhibition experiments, routinely consisting of 7 concentrations of the tested compounds, were analyzed using a non-linear regression curve-fitting computer program to obtain Ki values.

α₁ Human Adrenergic Receptors: To determine the potency of α₁ antagonists at the α₁ receptors, LM(tk⁻) cell lines stably transfected with the genes encoding the α₂A, α₂B, and α₂C receptors were used. The cell line expressing the α₂A receptor is designated L-α₂A, and was deposited on November 6, 1992 under ATCC Accession No. CRL 11180. The cell line expressing the α₂B receptor is designated L-NGC-α₂B, and was deposited on October 25, 1989 under ATCC Accession No. CRL10275. The cell line expressing the α₂C receptor is designated L-α₂C, and was deposited on November 6, 1992 under ATCC Accession No. CRL-11181. All the cell lines were deposited with the American Type Culture Collection, 12301 Parklawn Drive, Rockville, Maryland 20852, U.S.A. under the provisions of the Budapest Treaty for the International Recognition of the Deposit of Microorganisms for the Purposes of Patent Procedure. Cell lysates were prepared as described above (see Radioligand Binding Assays), and suspended in 25mM glycylglycine buffer (pH 7.6 at room temperature). Equilibrium competition binding assay were performed using [³H]rauwolscine (0.5nM), and nonspecific binding was determined by incubation with 10μM phentolamine. The bound
radioligand was separated by filtration through GF/B filters using a cell harvester.

Determination of the Activity of \( \alpha_1 \) Antagonists at Calcium Channels

The potency of \( \alpha_1 \) antagonists at calcium channels may be determined in competition binding assays of [3H]nitrendipine to membrane fragments of rat cardiac muscle, essentially as described by Glossman and Ferry (Methods in Enzymology 109:513-550, 1985). Briefly, the tissue is minced and homogenized in 50mM Tris-HCl (pH 7.4) containing 0.1mM phenylmethylsulfonyl fluoride. The homogenates are centrifuged at 1000 g for 15 minutes, and the resulting supernatant centrifuged at 45,000 g for 15 minutes. The 45,000 g pellet is suspended in buffer and centrifuged a second time. Aliquots of membrane protein are then incubated for 30 minutes at 37°C in the presence of [3H]nitrendipine (1nM), and nonspecific binding determined in the presence of 10μM nifedipine. The bound radioligand is separated by filtration through GF/B filters using a cell harvester.

The compounds described above were assayed using cloned human alpha adrenergic receptors. The preferred compounds were found to be selective \( \alpha_{1c} \) antagonists. The binding affinities of compounds 13-17 are illustrated in the following table.
Binding affinities of compounds 13-17 at cloned human α1d, α1b and α1a receptors.
