(57) **ABSTRACT**

A leadframe suitable for use in the packaging of at least two integrated circuit dice into a single integrated circuit package is described. The leadframe includes a plurality of leads. Each of a first set of the plurality of leads has a first side and a second side substantially opposite the first side of the lead. Additionally, each of the first and second sides of the first set of leads each include at least two solder pads. Each solder pad on a lead of the first set of leads is isolated from other solder pads on the same side of the lead with at least one recessed region adjacent the solder pad. In various embodiments, I/O pads from at least two dice are physically and electrically connected to the opposing sides of the leads.

METHOD AND LEADFRAME FOR PACKAGING INTEGRATED CIRCUITS

TECHNICAL FIELD

[0001] The present invention relates generally to the packaging of integrated circuits (ICs). More particularly, an IC package is described that includes two IC dice that share common leads.

BACKGROUND OF THE INVENTION

[0002] There are a number of conventional processes for packaging integrated circuit (IC) dice. By way of example, many IC packages utilize a metallic lead frame that has been stamped or etched from a metal sheet to provide electrical interconnects to external devices. The die may be electrically connected to the lead frame by means of bonding wires, solder bumps, or other suitable electrical connections. In general, the die and portions of the lead frame are encapsulated with a molding material to protect the delicate electrical components on the active side of the die while leaving selected portions of the lead frame exposed to facilitate electrical connection to external devices.

[0003] In some applications, it is desirable to leave the back surface (opposite the active surface) of the die exposed; that is, not to encapsulate the back surface of the die with molding material. By way of example, it may be desirable to leave the back surface of the die exposed in order to increase heat dissipation out of the die. This is especially relevant for packages used in power applications. Increasing heat dissipation out of an IC die generally results in greater device performance and stability.

[0004] While existing arrangements and methods for packaging IC devices work well, there are continuing efforts to improve the thermal performance of IC devices.

SUMMARY OF THE INVENTION

[0005] In one aspect, an integrated circuit package is described that includes two dice. The active surface of each die includes a plurality of I/O pads. The active surface of the first die is positioned adjacent first sides of the leads of a leadframe such that I/O pads from the first die are arranged adjacent corresponding solder pads on the first sides. Similarly, the active surface of the second die is positioned adjacent second sides of the leads opposite the first surfaces such that I/O pads from the second die are arranged adjacent corresponding solder pads on the second sides. Each of a first set of selected leads includes at least two solder pads on each of the first and second sides of the lead. Each solder pad on a selected lead is isolated from other solder pads on the same side of the lead with at least one recessed region adjacent the solder pad. A plurality of solder joints are arranged to physically and electrically connect I/O pads from the first or second die to associated adjacent solder pads on the leads. The solder from each solder joint that contacts an associated solder pad surface on a selected lead is confined to the solder pad surface by one or more adjacent recessed regions. In this way, a single leadframe can be utilized to package two dice, one on either side of the leads of the leadframe.

[0006] In another aspect, a method of packaging at least two integrated circuit dice into a single integrated circuit package utilizing a single leadframe is described. A first die is positioned onto a first side of a leadframe such that I/O pads on the first die are positioned adjacent corresponding solder

pads on first sides of selected leads of the leadframe. Solder bumps positioned between the I/O pads on the first die and the solder pads on the first sides of the leads are then reflowed to produce a first plurality of solder joints that physically and electrically connect the first die to the leads of the leadframe. Subsequently, the leadframe is positioned onto a set of spacers such that the first die is below the leadframe. The spacers are arranged to support the leadframe such that the die does not have to contact any other surface. A second die is positioned onto a second side of the leadframe opposite the first side of the leadframe such that I/O pads on the second die are positioned adjacent corresponding solder pads on second sides of the selected leads of the leadframe. Solder bumps positioned between the I/O pads on the second die and the solder pads on the second sides of the leads are then reflowed to produce a second plurality of solder joints that physically and electrically connect the second die to the leads of the leadframe. The spacers support the leadframe such that during the second reflowing the first plurality of solder joints are not compressed by the weight of the leadframe and are thus able to retain their shape.

BRIEF DESCRIPTION OF THE DRAWINGS

[0007] For a better understanding of the invention, reference should be made to the following detailed description taken in conjunction with the accompanying drawings, in which:

[0008] FIGS. 1A-D illustrate diagrammatic first cross-sectional side, second cross-sectional side, cross-sectional top and bottom views, respectively, of an IC package in accordance with an embodiment of the present invention.

[0009] FIGS. 2A-B illustrate diagrammatic cross-sectional side views of the IC package of FIG. 1 mounted on a printed circuit board in accordance with an embodiment of the present invention.

[0010] FIGS. 3A-B illustrate diagrammatic cross-sectional side and cross-sectional top views, respectively, of a three-die package in accordance with an embodiment of the present invention.

[0011] FIG. 4 is a flow chart illustrating a process of packaging integrated circuit dice in accordance with an embodiment of the present invention.

[0012] FIG. 5 illustrates an arrangement in which dice are mounted to each of two opposite sides of a leadframe.

[0013] Like reference numerals refer to corresponding parts throughout the drawings.

DETAILED DESCRIPTION OF EXAMPLE EMBODIMENTS

[0014] The present invention relates generally to the packaging of integrated circuits (ICs). More particularly, an IC package is described that includes two IC dice that share common leads.

[0015] In the following description, numerous specific details are set forth to provide a thorough understanding of the present invention. It will be apparent, however, to one skilled in the art that the present invention may be practiced without some or all of these specific details. In other instances, well known process steps have not been described in detail in order to avoid unnecessary obscuring of the present invention.

[0016] Various embodiments of the present invention will be described with reference to FIGS. 1-2. Aspects of the present invention provide an IC package that utilizes a lead-

frame in the packaging of at least two IC dice. The I/O pads on the active surfaces of the dice are physically and electrically connected with associated leads of the leadframe with solder joints. In some embodiments, the dice are packaged such that an exposed metallic layer deposited onto the back surface of at least one of the dice remains uncovered by molding compound used to encapsulate other portions of the dice, leads and solder joints.

[0017] Referring initially to FIGS. 1A-1D, an IC package 100 is described. IC package 100 is particularly suitable for use in power applications. Generally, package 100 may be referred to as a flip-chip-on-lead (FCOL) type package. FIGS. 1A and 1B illustrate cross-sectional side views of package 100 taken along lines B-B and C-C, respectively, shown in FIG. 1C, which illustrates a cross-sectional top view of package 100 taken along line A-A of FIG. 1A. IC package 100 includes a first bottom IC die 102 and a second top IC die 104. In some embodiments, both of the dice 102 and 104 may be configured for use in power applications.

[0018] The first bottom die 102 and second top die 104 have active surfaces 106 and 108, respectively. The active surfaces 106 and 108 are arranged so as to face one another and each include a plurality of bond pads 110 (although the die 102 would be hidden from view, the perimeters of the die 102 and bond pads 110 associated with the die 102 are illustrated with a dotted line in FIG. 1C). In some particular embodiments, the active surfaces 106 and 108 are mirror images of one another. More specifically, if the active surface 108 of the second top die 104 is positioned over and adjacent the active surface 106 of the first bottom die 102, the bond pads 110 on the active surface 108 of the top die 104 may align with corresponding similar functioning bond pads 110 on the active surface 106 of the bottom die 102. The bond pads 110 may be the original bond pads on the active surface of the die 102 or other input/output (I/O) pads that have been redistributed from the bond pads using various redistribution techniques (hereinafter, bond pads will be used interchangeably with I/O pads). Additionally, in various embodiments, underbump metallizations (UBMs) may be formed on the bond pads 110 of the dice 102 and 104 prior to solder bumping.

[0019] In various embodiments, the bottom IC die 102 includes a thin metallic layer 112 deposited onto the back surface 114 of the die as best illustrated in FIG. 1D, which illustrates the bottom surface of the package 100. The thin metallic layer 112 may be formed from any suitable metal or metallic alloy. By way of example, the thin metallic layer 112 may be an alloy of titanium, nickel and silver. The thin metallic layer 112 may also be applied to the back surface 114 of the die 102 with any suitable means including, for example, sputtering. The metallic layer 112 may serve as a heat dissipation medium for transferring thermal energy out of the die 102. In various embodiments, the back surface 114 of the die 102 is intended to be soldered directly to a desired substrate, such as a PCB, to provide for enhanced heat dissipation out of the die. Since solder does not generally adhere well to Si, the metallic layer may serve as an intermediary between the solder and the Si. In other embodiments, such as in analog applications, it is desirable to electrically connect the back surface 114 of the die 102 to a PCB to allow control over the electrical potential of the back region of the die. In some embodiments, a similar thin metallic layer 116 is also deposited onto the back surface 118 of the top die 104.

[0020] Package 100 additionally includes a leadframe having a plurality of leads 120. Each lead 120 may be configured

as a power lead intended for coupling to an external power or ground line. By way of example, power leads 120 may be configured to carry at least approximately 1 Watt. In other applications, each power lead 120 may be configured to carry much higher powers. Each lead 120 includes an inner lead finger portion 120a, a middle lead portion 120b and an outer lead portion 120c. In various embodiments, the leads 120 are arranged such that the inner lead finger portions 120a are arranged in interlaced adjacent rows over the active surface 106 of the first bottom die 102. More specifically, the leads 120 may be arranged such that the middle portion 120b and outer portion 120c of each lead 120 is positioned on an opposite side of the die 102 as the middle and outer lead portions of the leads 120 immediately adjacent to the respective lead.

[0021] In the embodiment illustrated in FIGS. 1A-D, which illustrate a dual inline package (DIP) format, four leads 120 are configured such that the four associated inner lead finger portions 120a are arranged in four interlaced rows over the active surface 106 of the bottom die 102. The outer portions 120c of the corresponding leads 120 are arranged such that two of the outer portions 120c of the leads 120 extend from each of two opposite sides of the package 100.

[0022] Furthermore, a number of signal leads 122 may be provided in addition to the power leads 120. For example, in the illustrated embodiment, two signal leads 122 are provided. The illustrated leads are arranged on opposite sides of one end of the package 100. In other embodiments, package 100 may include only one signal lead 122, while in still other embodiments, package 100 may include more than two signal leads 122. Leads 122 are generally intended for connection to signal or control lines and any suitable number of signal leads 122 may be present in package 100. The associated inner regions 122a of the leads 122 may be positioned in a single row over the active surface 106 of the bottom die 102 as illustrated in FIG. 1C. The outer portions 122c of the leads 122 are arranged to extend from opposite sides of the package 100. The described arrangement forms a DIP 100 having five rows of leads over the active surface 106 of the die 102 and six corresponding external outer lead portions 120c and 122c, three of which (two outer portions 120c and one outer portion 122c) extend from each of two opposite sides of the package 100.

[0023] Package 100 may also include a number of additional internal leads 124. Internal leads 124 may be used to connect associated bond pads 110 on the active surfaces 106 and 108 of the two dice 102 and 104 with one another. In the illustrated embodiment, the internal leads 124 do not extend out of the package 100. The leads 124 enable the dice 102 and 104 to communicate with one another. By way of example, in one embodiment, one of the dice 102 or 104 may serve as a master chip that regulates the operations of the other die. In one alternate embodiment, bond pads 110 on each of the respective dice 102 and 104 may be connected with one another with larger solder joints that span the gap between associated bond pads 110 on each of the respective dice thereby eliminating the need for the leads 124.

[0024] Each of the inner lead portions 120a and 122a and the internal leads 124 includes at least one conductive solder pad 126. The inner lead portions 120a and 122a are arranged such that the solder pads 126 are positioned adjacent corresponding bond pads 110 on the active surfaces 106 and 108 of the dice 102 and 104, respectively. Each bond pad 110 is physically and electrically connected to one of the associated leads 120, 122 or 124 with a solder ball joint 128. In various

embodiments, the outer portions **120c** and **122c** of the leads **120** and **122** additionally include package contacts **130** on the bottom surfaces of the leads. In some embodiments, the leads **120**, **122** and **124** may be etched, half-etched, or otherwise thinned relative to the solder pads **126** and/or package contacts **130** as will be described in more detail below.

[0025] In many embodiments, a single lead **120** or **122** may be electrically and physically connected with one or more bond pads **110** on each of the dice **102** and **104**, as illustrated in FIGS. 1A and B. This leadframe arrangement especially facilitates the packaging of dice **102** and **104** whose respective active surface **106** and **108** and associated bond pads **110** are mirror images of one another. More specifically, a single lead **120** or **122** may be used to bias bond pads **110** on both dice **102** and **104** simultaneously.

[0026] In various embodiments, one or more leads **120** are each connected with multiple I/O pads **110** on each of the active surfaces **106** and **108** of the dice **102** and **104**. By way of example, a single inner lead finger **120a** may include multiple solder pads **126**, each of which is to be physically and electrically bonded to one of multiple I/O pads **110** designated for connection with power or ground lines, which typically carry higher current and power. The number of I/O pads **110** connected with each lead **120** may vary widely. By way of example, anywhere from 1 to 8 I/O pads **110** on each die **102** and **104** may be connected with corresponding solder pads **126** on a single lead **120**. In some high power applications, an even greater number of I/O pads may be connected with a single lead **120**. In the embodiment illustrated in FIGS. 1A-D, the leads **120** that are intended for connection to higher current power or ground lines and are each connected with three corresponding I/O pads **110** on each of the top and bottom dice **104** and **102**. In contrast, the leads **122** are generally intended for connection to signal or control lines and are each connected with a single I/O pad **110** on each of the top and bottom dice **104** and **102** via a single solder joint **128**.

[0027] In some embodiments, the leads may be etched to form recessed regions **121** around the solder pads **126** on both sides of the leads **120** in order to prevent the spread of solder between adjacent solder pads **126** and along other surfaces of each lead. The recessed regions **121** essentially form a moat around each solder pad **126** that serves to isolate the solder pad from the rest of the associated lead surfaces. The recessed regions **121** may be formed by any suitable means. By way of example, the recessed regions **121** may be formed by etching the top surface of the lead frame panel. The formation and use of recessed regions to isolate solder pads is described in more detail in U.S. patent application Ser. No. 11/691,429, which is incorporated by reference herein.

[0028] Each recessed region **121** is recessed sufficiently from the surface of the solder pads of the associated leads to prevent flux and solder from spreading to undesired surfaces of the lead **120**. More particularly, the recessed regions **121** are preferably etched sufficiently deep such that the spread of flux or solder is limited to the solder pads **126** by the surface tension of the flux or solder, respectively. By way of example, the recessed regions **121** are preferably recessed to a depth in the range of approximately 2 to 4 mils in typical lead frame designs although deeper or shallower recessed regions may be provided. In one preferred embodiment the recessed regions on both sides of the leads are half-etched simultaneously thus saving valuable processing time. The aforementioned recess depths work well for a variety of solder pad geometries and sizes.

[0029] It should be appreciated that the resulting “raised” solder pads limit the spread of solder since (a) they tend to define the areas cleaned by flux, and (b) the surface tension of the solder tends to further help prevent the solder from extending beyond the edges of the solder pads **126**.

[0030] In one embodiment, the recessed regions **121** are etched such that the solder pads **126** are substantially circular. In an alternate embodiment, the solder pads **126** may be substantially oval, rectangular or square (with or without rounded corners). However, in many applications it is preferable to have substantially circular solder pads rather than rectangular solder pads or other solder pads having geometries with sharp corners. More particularly, sharp corners may have the effect of counteracting the forces of surface tension that confine the flux and solder to the surfaces of the solder pads **126**. Additionally, in some applications it will be desirable to form solder pads **126** wider than other portions of their associated leads **208**.

[0031] The recessed regions **121** preferably extend to a sufficient length along the leads so that the flux may not bridge the recessed regions between the solder pads **126** and the rest of the leads. Additionally, in some embodiments it may be desirable for the recessed regions **121** to extend to a greater length.

[0032] It should be appreciated that the solder pads **126** defined by the recessed regions **121** may also be advantageously used to control the standoff height between the leads and an associated die. The standoff height between the leadframe (e.g., solder pad **126**) and the die (e.g., I/O pad **110**) is generally a function of the volume of solder in the solder bump **128** as well as the surface area and geometry of the associated UBM (or I/O pad **110**) and solder pad **126**. Therefore, by controlling the volume of solder as well as the surface areas and geometries of the solder pad **126** and I/O pad **110**, a desired standoff height may be achieved. Furthermore, since the same process may be applied to every solder joint, a uniform standoff height may be achieved across the entire die.

[0033] In the embodiment illustrated in FIG. 1A, the dice **102** and **104** are offset from one another. The offset results from the staggering of the solder pads **126** on opposite sides of the leads. More particularly, the recessed regions **121** in FIG. 1A are half etched and as such, the solder pads **126** on both sides of the lead **120** may not overlie one another. In other embodiments, the recessed regions **121** may be recessed to a depth of less than halfway through the lead thereby allowing the solder pads **126** on both sides of the lead to directly overlie one another thereby permitting the dice to directly overlie one another.

[0034] As will be appreciated by those familiar with the art, power or ground lines generally carry higher current than other signal or control lines. The aforementioned arrangement allows the current through a single lead **120** to be shared by multiple associated I/O pads **110** on each of the top and bottom dice **104** and **102**, and their associated solder ball joints **128**. The amount of current carried by each solder joint **128** is limited in part by the size of the solder joint (e.g., the diameter of the solder joint). The diameter of the solder joint **128** is, in turn, generally limited by the size of the corresponding I/O pad **110**, which is in turn limited by the available real estate on the active surfaces **106** and **108** of the dice **102** and **104**. More particularly, for a given die footprint, the layout (distribution), size and shape of the I/O pads **110** is limited by the regions on the active surfaces of the dice available for

bonding and the total area of the active surfaces of the dice as well as proximity constraints placed on the I/O pads.

[0035] Those familiar with the art will appreciate that the current carrying and heat dissipation capabilities of solder ball joints far exceed those of bonding wires. Generally, as the number and diameter of the solder ball joints **128** increase, the current carrying and heat dissipation capabilities increase. Additionally, as the diameters of the solder ball joints **128** increase, the resistance through the solder ball joints decreases. As a result of their larger diameters and the relatively shorter distance traveled through a solder ball joint as compared to a typical bonding wire, the electrical resistance through solder ball joints is far below that of typical bonding wires. By way of example, a typical solder ball joint may have a resistance of approximately 0.5 mΩ while a corresponding bonding wire used in a similar application may have a resistance in the range of approximately 60 to 100 mΩ.

[0036] It will be appreciated by those skilled in the art that, although a specific lead frame arrangement has been described and illustrated, embodiments of the present invention may utilize an extremely wide variety of other leadframe configurations as well. Additionally, although described with references to top and bottom dice and various surfaces, it should be appreciated that this context is intended solely for use in describing the structure and may not coincide with the final orientation of the package after subsequent attachment to a PCB or other suitable substrate.

[0037] In the illustrated embodiment, portions of the dice **102** and **104** and leads **120**, **122** and **124** are encapsulated with a molding material or compound **132**. The molding compound is generally a non-conductive plastic or resin having a low coefficient of thermal expansion. Package **100** may be encapsulated in such a way as to prevent molding material **132** from covering or intruding over the metallic layer **112** on the back surface **114** of the bottom die **102**. Package **100** may also be encapsulated such that molding material is prevented from covering or intruding over a metallic layer **116** on the back surface **118** of the top die **104**. The molding material does encapsulate other portions of the dice **102** and **104**, the solder joints **128**, leads **124** and generally at least the inner portions **120a** and **122a** and middle portions **120b** and **122b** of the leads **120** and **122**, respectively. In the embodiment illustrated in FIGS. 1A-1D, the outer portions of the leads **120** and **122** extend from the sides of the encapsulated package **100** and are bent into a characteristic gull-wing formation to facilitate electrical connection with a printed circuit board (PCB) or other suitable substrate. Additionally, the package contacts **130** on the bottom surfaces of the leads **120** and **122** may be configured so as to be coplanar with the bottom or back surface of the metallic layer **112**.

[0038] In the embodiment illustrated in FIGS. 2A and B, the package contacts **130** on the bottom surfaces of the leads **120** and **122** of package **100** are physically and electrically connected with corresponding contacts **234** on a PCB **236** via solder joints **228**. In various embodiments, the metallic layer **112** is also physically and electrically connected to an associated contact surface **238** on the PCB **236**. Additionally, in some embodiments, a heat sink **240** may be soldered to the metallic layer **116** on the top die **104**. In the illustrated embodiment, the heat sink **240** is also soldered to corresponding contact surfaces **242** on the PCB **236**. Although a specific heat sink **240** is illustrated, it will be appreciated that any suitable heat sink may be incorporated.

[0039] The described arrangement provides multiple efficient and direct mechanisms for dissipating heat out of the package **100**. More particularly, by soldering or otherwise connecting the metallic layer **112** on the back surface **114** of the bottom die **102** to the PCB **236**, a direct thermally conductive path is created between the die **102** and the PCB **236**. Additionally, the heat sink **240** provides an efficient means for transferring heat out of the top of the package **100**. Furthermore, as already described, the solder joints **128** also provide an efficient thermal path for dissipating thermal energy out of the package **100** via the leads **120** to the contacts **234** on the PCB **236**. Thus, embodiments of the present invention provide three efficient means of dissipating heat out of the package **100**.

[0040] Furthermore, the described arrangement of the dice **102** and **104** and leads **120**, **122** and **124** enables the production of a package **100** having double the effective silicon density and hence potentially double the performance while maintaining a conventional package size. Conversely, one could retain a desired silicon density and performance while halving the footprint of the package. More specifically, by advantageously utilizing the volume in the top half of the package to incorporate a second die, the number of transistors for a given package footprint may be doubled. Moreover, by soldering the exposed metallic layer on the back surface of the bottom die to a PCB and/or soldering a heat sink to an exposed metallic layer on the back surface of the top die, the thermal performance of the package is increased sufficiently to enable the full utilization of both dice. Furthermore, in embodiments in which mirror image dice are used, no additional leads are required as each lead may be connected with corresponding I/O pads on both dice.

[0041] Although the embodiments described thus far have focused on the packaging of two IC dice, it will be appreciated that, in other embodiments, more than two dice may be packaged into a single IC package as well. By way of example, FIGS. 3A and 3B illustrate an alternative embodiment of a package **100** which includes two top dice **104** and **304**. In the embodiment illustrated in FIG. 3B, the perimeter of the bottom die **102** is illustrated with a dashed line while the perimeters of the top dice **104** and **304** are each illustrated with dotted lines. In some embodiments, one or both of the top dice **104** and **304** may be utilized as a control chip for regulating operations in the bottom die **102**. In these embodiments, bond pads **110** on one or both of the dice **104** and **304** may be connected with bond pads on the bottom die **102** via internal leads **124**. Depending upon the application, the top dice **104** and **304** may or may not include exposed metallic layers on their respective back surfaces. In some embodiments, the top dice **104** and **304** may also be electrically connected with one another to permit electrical communication therebetween. As will be appreciated by those of skill in the art, the described arrangement facilitates the production of system-in-package (SIP) or multi-chip module (MCM) package designs. Furthermore, although only a single embodiment of a three-chip (die) package is illustrated, it will be appreciated that both the number and arrangement of the leads and dice may vary widely.

[0042] With reference to FIGS. 4 and 5 a process **400** of packaging at least two integrated circuit dice with a single leadframe device area will be described. A leadframe such as those described above is provided at **402**. At **404** a first die is positioned onto a first side of the leadframe. It will be appreciated that in various embodiments the leadframe is a single

leadframe device area of a larger leadframe panel having a multitude of leadframe device areas each of which is suitable for use in packaging IC dice. By way of example, the leadframe panel may be in the form of a strip with side rails and other supporting structures supporting the device areas of the leadframe panel. In these embodiments, dice may be positioned on each device area of the leadframe panel. Additionally, in some embodiments, multiple dice may be positioned within a single device area (such as in the embodiment illustrated in FIGS. 3A and 3B described above).

[0043] In various embodiments, one or both of the dice and/or leads of the leadframe panel include solder bumps deposited thereon. At 406, the solder bumps are reflowed to form solder joints that physically and electrically connect the solder pad surfaces on the leads and I/O pads on the dice.

[0044] At 408 the populated leadframe or leadframe panel is flipped and subsequently positioned on a set of spacers at 410. FIG. 5 illustrates a single leadframe device area 500 having a first die 502 physically and electrically connected to leads 504 on a first side of the leadframe via a first set of solder joints 506. In the illustrated embodiment, side rails 509 of the leadframe panel are each positioned onto a spacer 508 to support the leadframe such that the dice 502 do not have to rest on any other surface.

[0045] At 412 a second die (or set of dice) 510 is positioned onto the second side of the leadframe such that I/O pads on the second die are positioned over the same leads 504 used to connect the first die. The populated leadframe 500 is then reflowed again at 414 to produce solder joints 512 that physically and electrically connect the bottom die (or dice) 510 to the second sides of the same leads 504. It should be noted that since the spacers 508 support the leadframe 500 during the second reflow the weight of the leadframe, dice and solder does not compress the first set of solder joints 506 which are also melted during the second reflow. Additionally, it has been observed that the cohesion of the solder in the solder joints 506 is sufficient to support the hanging dice 502 during the second reflow. Subsequently, the populated leadframe panel is then encapsulated at 416 and singulated to produce individual IC packages (if necessary) at 418.

[0046] The foregoing description, for purposes of explanation, used specific nomenclature to provide a thorough understanding of the invention. However, it will be apparent to one skilled in the art that the specific details are not required in order to practice the invention. Thus, the foregoing descriptions of specific embodiments of the present invention are presented for purposes of illustration and description. They are not intended to be exhaustive or to limit the invention to the precise forms disclosed. It will be apparent to one of ordinary skill in the art that many modifications and variations are possible in view of the above teachings.

[0047] The embodiments were chosen and described in order to best explain the principles of the invention and its practical applications, to thereby enable others skilled in the art to best utilize the invention and various embodiments with various modifications as are suited to the particular use contemplated. It is intended that the scope of the invention be defined by the following claims and their equivalents.

What is claimed is:

1. An integrated circuit package, comprising:

a first die, the first die having an active surface and a back surface substantially opposite the active surface of the first die, the active surface including a first plurality of I/O pads;

a second die, the second die having an active surface and a back surface substantially opposite the active surface of the second die, the active surface including a second plurality of I/O pads;

a plurality of leads, each lead having a first side and a second side substantially opposite the first side of the lead, the active surface of the first die being positioned adjacent first sides of selected leads such that I/O pads from the first plurality of I/O pads are arranged adjacent corresponding solder pads on the first sides of the selected leads, the active surface of the second die being positioned adjacent second sides of the selected leads such that I/O pads from the second plurality of I/O pads are arranged adjacent corresponding solder pads on the second sides of the selected leads, each selected lead including at least two solder pads on each of the first and second sides of the lead, each solder pad on a selected lead being isolated from other solder pads on the same side of the lead with at least one recessed region adjacent the solder pad; and

a plurality of solder joints that are arranged to physically and electrically connect selected ones of the I/O pads from the first die to corresponding solder pads on the first sides of associated selected leads and to physically and electrically connect selected ones of the I/O pads from the second die to corresponding solder pads on the second sides of the associated selected leads, wherein the solder of each solder joint that contacts an associated solder pad surface on a selected lead is substantially confined to the solder pad surface by one or more adjacent recessed regions.

2. An integrated circuit package as recited in claim 1, wherein each selected lead includes at least three solder pads on each of the first and second sides of the lead.

3. An integrated circuit package as recited in claim 1, wherein the solder pads on the first sides of the selected leads do not directly overlie the solder pads on the second sides of the selected leads.

4. An integrated circuit package as recited in claim 1, wherein the pitch between a solder pad on the first side of a selected lead and a solder pad on the second side of the lead is substantially half the pitch between adjacent solder pads on the same side of the lead.

5. An integrated circuit package as recited in claim 1, wherein the solder pads on the first sides of the selected leads directly overlie the solder pads on the second sides of the selected leads.

6. A leadframe suitable for use in the packaging of at least two integrated circuit dice into a single integrated circuit package, the leadframe comprising:

a plurality of leads, each of a first set of the plurality of leads having a first side and a second side substantially opposite the first side of the lead, each of the first and second sides of the first set of leads each including at least two solder pads, each solder pad on a lead of the first set of leads being isolated from other solder pads on the same side of the lead with at least one recessed region adjacent the solder pad.

7. A leadframe as recited in claim 6, wherein each lead of the first set of leads includes at least three solder pads on each of the first and second sides of the lead.

8. A leadframe as recited in claim 6, wherein each lead of the first set of leads includes at least eight solder pads on each of the first and second sides of the lead.

9. A leadframe as recited in claim 6, wherein the solder pads on the first sides of the first set of leads do not directly overlie the solder pads on the second sides of the leads.

10. A leadframe as recited in claim 6, wherein the pitch between a solder pad on the first side of a lead of the first set of leads and a solder pad on the second side of the lead is substantially half the pitch between adjacent solder pads on the same side of the lead.

11. A leadframe as recited in claim 6, wherein the solder pads on the first sides of the leads of the first set of leads directly overlie the solder pads on the second sides of the leads.

12. A leadframe as recited in claim 6, wherein widths of selected solder pads are wider than their associated leads.

13. A leadframe as recited in claim 6, wherein each recessed region is recessed to a depth in the range of approximately 2 to 4 mils from the surface of the associated solder pad.

14. A leadframe as recited in claim 6, wherein each recessed region is recessed to a depth of approximately half the thickness of the associated lead.

15. A leadframe as recited in claim 6, wherein the solder pads are substantially circular.

16. A method of packaging at least two integrated circuit dice into a single integrated circuit package utilizing a single leadframe, the method comprising:

positioning a first die onto a first side of a leadframe such that I/O pads on the first die are positioned adjacent corresponding solder pads on first sides of selected leads of the leadframe;

reflowing solder bumps positioned between the I/O pads on the first die and the solder pads on the first sides of the leads to produce a first plurality of solder joints that physically and electrically connect the first die to the leads of the leadframe;

positioning the leadframe onto a set of spacers such that the first die is below the leadframe, the spacers being arranged to support the leadframe such that the die does not have to contact any other surface;

positioning a second die onto a second side of the leadframe opposite the first side of the leadframe such that I/O pads on the second die are positioned adjacent corresponding solder pads on second sides of the selected leads of the leadframe; and

reflowing solder bumps positioned between the I/O pads on the second die and the solder pads on the second sides of the leads to produce a second plurality of solder joints that physically and electrically connect the second die to the leads of the leadframe, whereby the spacers support the leadframe such that during the second reflowing the first plurality of solder joints are not compressed by the weight of the leadframe.

17. A method as recited in claim 16, wherein the first plurality of solder joints are melted during the second reflowing and wherein the cohesion of the solder is sufficient to support the weight of the first die.

18. A method as recited in claim 16, wherein selected I/O pads on the first die and selected I/O pads from the second die are connected to the same leads.

19. A method as recited in claim 16, wherein multiple I/O pads on the first die are connected with a single selected lead and wherein multiple I/O pads on the second die are connected with the same single selected lead.

20. A method as recited in claim 16, wherein either or both of the first and second sides of the leadframe have I/O pads from at least two dice connected with solder pads on the same side of the leadframe.

21. A method as recited in claim 16, wherein the leadframe is a single leadframe device area of a larger leadframe panel that includes a plurality of device areas each of which is configured for use it packaging at least one die on either side of the leadframe device area.

22. A method as recited in claim 21, further comprising encapsulating the leadframe panel and singulating the leadframe panel to produce a plurality of integrated circuit packages each including at least two dice.
