A surgical instrument including a handle portion, a body portion, an articulating tool assembly and a locking assembly is disclosed. The handle portion includes a movable handle. The body portion extends distally from the handle portion and defines a first longitudinal axis. The articulating tool assembly defines a second longitudinal axis and is movable from a first position where the second longitudinal axis is substantially aligned with the first longitudinal axis to at least a second position where the second longitudinal axis is at an angle to the first longitudinal axis. The locking assembly includes a member that is advanceable distally with respect to the body portion. The member engages the articulating tool assembly upon manipulation of the movable handle to move an anvil and a cartridge assembly in approximation with one another to help maintain the articulating tool assembly in its first position.

SURGICAL INSTRUMENT INCLUDING A LOCKING ASSEMBLY

TECHNICAL FIELD

[0001] The present disclosure relates to a surgical instrument and disposable loading unit including a locking assembly. More particularly, the present disclosure relates to a surgical instrument which includes a locking assembly for retaining a tool assembly of an articulating surgical instrument, e.g., a linear stapler, in a predetermined position.

BACKGROUND

[0002] Surgical instruments which include a tool assembly mounted on a distal end of a body portion of the surgical instrument for articulation are well known. Typically, such surgical instruments include articulation control mechanisms which allow an operator to remotely articulate the tool assembly in relation to the body portion of a surgical instrument to allow the operator to more easily access, operate on, and/or manipulate tissue.

[0003] Such articulating tool assemblies have become desirable, especially in the endoscopic surgical procedures. In an endoscopic surgical procedure, the distal end of a surgical instrument is inserted through small incisions in the body to access a surgical site. Typically, a appropriately sized cannula, e.g., 5 mm, 10 mm, etc., is inserted through the body incision to provide a guide channel for accessing the surgical site. Because it is desirable to provide small body incisions so that there is less scarring, reduced trauma to the patient, faster healing time, the tolerances between the surgical instrument and the inner diameter of the cannula are small.

[0004] When a surgical instrument having an articulating tool assembly is used during an endoscopic procedure, the articulating tool assembly is generally in its non-articulated position (i.e., a position in which the longitudinal axis of the tool assembly is aligned with the longitudinal axis of the body portion of the surgical instrument), during insertion of the tool assembly through a cannula or small body incision. Movement of the tool assembly to an articulated position, even slightly misaligned with the body portion of the surgical instrument, may interfere with and/or prevent insertion of the distal end of the surgical instrument through the cannula or small body incision.

[0005] During manipulation or handling of a surgical instrument having an articulating tool assembly, it is not uncommon for the tool assembly to be jarred or bumped such that the tool assembly inadvertently is moved from its non-articulated position to an articulated position. As discussed above, this is undesirable, especially where the surgical instrument is to be used in an endoscopic surgical procedure. In addition, the ability of the tool assembly to hold its position with respect to the handle portion will affect how well a surgeon can manipulate tissue using the tool assembly.

SUMMARY

[0006] The present disclosure relates to a surgical instrument including a handle portion, a body portion, an articulating tool assembly and a locking assembly. The handle portion includes a movable handle. The body portion extends distally from the handle portion and defines a first longitudinal axis. The articulating tool assembly defines a

second longitudinal axis, is disposed at a distal end of the body portion and is movable from a first position where the second longitudinal axis is substantially aligned with the first longitudinal axis to at least a second position where the second longitudinal axis is at an angle to the first longitudinal axis. The articulating tool assembly includes an anvil and a cartridge assembly which are movable into approximation with one another by manipulation of the movable handle. The locking assembly includes a member that is advanceable distally with respect to the body portion. The member engages the articulating tool assembly upon manipulation of the movable handle to move the anvil and cartridge assembly in approximation with one another to help maintain the articulating tool assembly in its first position.

[0007] In an embodiment of the disclosure, the locking assembly includes a pivot plate in mechanical cooperation with the articulating tool assembly and the member is a finger in mechanical cooperation with the body portion. It a disclosed embodiment, the pivot plate includes at least one slot (e.g., five slots) therein and is securable to a portion of the articulating tool assembly. Here, the finger extends distally from a portion of the body portion and is engagable with the at least one slot (e.g., a wedge-shaped slot). In such an embodiment, partial activation of the movable handle causes the finger to move towards the at least one slot.

[0008] In a disclosed embodiment, the locking assembly includes at least one biasing element (e.g., at least one spring) which biases the member distally towards the pivot plate. In an embodiment, the locking assembly includes a link in mechanical engagement with the pivot plate (e.g., pivotably engaged) and the member (e.g., slidable).

[0009] In a disclosed embodiment, the articulating tool assembly is part of a disposable loading unit. The present disclosure also relates to a disposable loading unit that includes the articulating tool assembly and the locking assembly, as described above.

DESCRIPTION OF THE DRAWINGS

[0010] Various embodiments of the presently disclosed surgical instrument are disclosed herein with reference to the drawings, wherein:

[0011] FIG. 1 is a side perspective view from the distal end of one embodiment of the presently disclosed surgical instrument with articulating tool assembly;

[0012] FIG. 1A is a side perspective view from the proximal end of a disposable loading unit (DLU) of the surgical instrument shown in FIG. 1 including the tool assembly;

[0013] FIG. 2 is a side perspective view of the distal end of mounting assembly and tool assembly, with parts separated, of the DLU of the surgical instrument shown in FIG. 1;

[0014] FIG. 3 is a side perspective view of the mounting assembly and the proximal body portion of the DLU shown in FIG. 1A with parts separated;

[0015] FIG. 3A is a side perspective view of a coupling member of the surgical instrument shown in FIG. 1;

[0016] FIG. 3B is a side perspective view of an upper mounting portion of the mounting assembly of the DLU of the surgical instrument shown in FIG. 1;

[0017] FIG. 3C is a side perspective view of a lower mounting portion of the mounting assembly of the DLU of the surgical instrument shown in FIG. 1;

[0018] FIG. 3D is a side perspective view from above the proximal body portion, the mounting assembly and the tool

assembly of the DLU of the surgical instrument with the tool assembly in its non-articulated position;

[0019] FIG. 3E is a side perspective view from above the proximal body portion, the mounting assembly and the tool assembly shown in FIG. 3D with the tool assembly in an articulated position;

[0020] FIG. 3F is a side perspective view from below the proximal body portion, the mounting assembly and the tool assembly of the DLU of the surgical instrument with the tool assembly in its non-articulated position;

[0021] FIG. 3G is a side perspective view from below the proximal body portion, the mounting assembly and the tool assembly shown in FIG. 3F with the tool assembly in an articulated position;

[0022] FIG. 4 is a side cross-sectional view of the tool assembly of the DLU shown in FIG. 1A;

[0023] FIG. 5 is a top perspective view of the lock member actuator of the proximal body portion locking mechanism shown in FIG. 3;

[0024] FIG. 6 is a bottom perspective view of a locking member of the locking mechanism shown in FIG. 3;

[0025] FIG. 7 is a top view of the proximal end of the DLU proximal body portion shown in FIG. 1A with the locking mechanism in its locked position;

[0026] FIG. 8 is a cross-sectional view taken along section lines 8-8 of FIG. 7;

[0027] FIG. 9 is a top view of the proximal end of the DLU proximal body portion shown in FIG. 1A with the locking mechanism in its unlocked position;

[0028] FIG. 10 is a cross-sectional view taken along section lines 10-10 of FIG. 9;

[0029] FIG. 11 is a side perspective view of the DLU and surgical instrument shown in FIG. 1 prior to attachment of the DLU to the surgical instrument;

[0030] FIG. 12 is a top view of the proximal end of the DLU and the distal end of the surgical instrument shown in FIG. 11 prior to attachment to the distal end of the surgical instrument;

[0031] FIG. 13 is a top view of the proximal end of the DLU shown in FIG. 11 as the DLU is advanced linearly into the distal end of the surgical instrument;

[0032] FIG. 14 is a top view of the proximal end of the DLU and the distal end of the surgical instrument shown in FIG. 12 after the DLU has been advanced linearly but prior to locking the DLU to the surgical instrument;

[0033] FIG. 15 is a top view of the proximal end of the DLU and the distal end of the surgical instrument shown in FIG. 13 after the DLU has been advanced linearly and rotatably locked into the surgical instrument;

[0034] FIG. 16 is a perspective view of a locking assembly for use with a surgical instrument in accordance with an embodiment of the present disclosure;

[0035] FIG. 17 is a perspective view of various components of the locking assembly of FIG. 16;

[0036] FIG. 18 is an enlarged perspective view of a portion of the locking assembly of FIGS. 16 and 17 illustrated with the articulating tool assembly in a non-articulated position;

[0037] FIG. 19 is an enlarged perspective view of a portion of the locking assembly of FIGS. 16-18 and including a link;

[0038] FIG. 20 is an enlarged perspective view of a portion of the locking assembly of FIGS. 16-19 illustrated with the articulating tool assembly in an articulated position;

[0039] FIG. 21 is an enlarged perspective view of another locking assembly for use with a surgical instrument in accordance with an embodiment of the present disclosure;

[0040] FIG. 22 is an enlarged bottom perspective view of the locking assembly of FIG. 21;

[0041] FIG. 23 is a perspective view of a drive beam having a plurality of layers and a closure apparatus in accordance with an embodiment of the present disclosure;

[0042] FIG. 24 is a perspective view of the drive beam and closure apparatus of FIG. 23 with parts separated;

[0043] FIG. 25 is a cross-sectional view of a portion of the drive beam and closure apparatus of FIGS. 23 and 24;

[0044] FIG. 26 is a cross-sectional view of a drive beam and a closure apparatus in accordance with an embodiment of the present disclosure;

[0045] FIG. 27 is a cross-sectional view of the drive beam and closure apparatus of FIG. 26;

[0046] FIG. 28 is a perspective view of a tool assembly in accordance with an embodiment of the present disclosure; and

[0047] FIG. 29 is an assembly view of the tool assembly of FIG. 28.

DETAILED DESCRIPTION OF EMBODIMENTS

[0048] Embodiments of the presently disclosed surgical instrument and DLU will now be described in detail with reference to the drawings, in which like reference numerals designate identical or corresponding elements in each of the several views.

[0049] Referring to FIG. 1, surgical instrument 500 includes a handle portion 510, a body portion 512, and a disposable loading unit ("DLU") 16. Handle portion 510 includes a stationary handle 514 and a movable handle or trigger 516. Movable handle 516 is movable in relation to stationary handle 514 to advance a control rod 520 which projects from the distal end of body portion 512. Handle portion 510 and body portion 512 may be constructed in the manner disclosed in U.S. Pat. No. 6,330,965 which is hereby incorporated herein in its entirety by reference. Alternately, other surgical instruments can be used with DLU 16 to perform endoscopic surgical procedures.

[0050] Referring to FIGS. 1 and 1A, briefly, DLU 16 includes a tool assembly 17, a proximal body portion 200 and a mounting assembly 202. Body portion 200 has a proximal end adapted to releasably engage the distal end of a surgical instrument 500 (FIG. 11) in the manner to be discussed in detail below. Mounting assembly 202 is pivotally secured to a distal end of body portion 200 and is fixedly secured to a proximal end of tool assembly 17. Pivotal movement of mounting assembly 202 about an axis perpendicular to a longitudinal axis of body portion 200 affects articulation of tool assembly 17 between a non-articulated position in which the longitudinal axis of tool assembly 17 is aligned with the longitudinal axis of body portion 200 and an articulated position in which the longitudinal axis of tool assembly 17 is disposed at an angle to the longitudinal axis of body portion 200.

[0051] Referring to FIGS. 2-4, tool assembly 17 includes a cartridge assembly 18 and an anvil assembly 20. Anvil assembly 20 includes an anvil portion 28 having a plurality of staple deforming concavities 30 (FIG. 4) and a cover plate 32 secured to a top surface of anvil portion 28. Cover plate 32 and anvil portion 28 define a cavity 34 (FIG. 4) therebetween which is dimensioned to receive a distal end of a drive

assembly 212 (FIG. 3). Cover plate 32 encloses the distal end of drive assembly 212 to prevent pinching of tissue during actuation of DLU 16. A longitudinal slot 38 extends through anvil portion 28 to facilitate passage of a retention flange 40 of drive assembly 212. A camming surface 42 formed on anvil portion 28 is positioned to engage a pair of cam members 40a supported on retention flange 40 of drive assembly 212 to effect approximation of the anvil and cartridge assemblies. A pair of pivot members 44 are formed. A pair of stabilizing members 50 engage a respective shoulder 52 formed on carrier 48 to prevent anvil portion 28 from sliding axially in relation to staple cartridge 54 as camming surface 42 is pivoted about pivot members 44.

[0052] Cartridge assembly 18 includes carrier 48 which defines an elongated support channel 56 which is dimensioned and configured to receive staple cartridge 54. Corresponding tabs 58 and slots 60 formed along staple cartridge 54 and elongated support channel 56, respectively, function to retain staple cartridge 54 at a fixed location within support channel 56. A pair of support struts 62 formed on staple cartridge 54 are positioned to rest on side walls of carrier 48 to further stabilize staple cartridge 54 within support channel 56. Carrier 48 has slots 46 for receiving pivot members 44 of anvil portion 28 and allowing anvil portion 28 to move between spaced and approximated positions.

[0053] Staple cartridge 54 includes retention slots 64 (FIG. 2) for receiving a plurality of staples or fasteners 66 and pushers 68. A plurality of laterally spaced apart longitudinal slots 70 extend through staple cartridge 54 to accommodate upstanding cam wedges 72 of an actuation sled 74 (FIG. 2). A central longitudinal slot 76 extends along substantially the length of staple cartridge 54 to facilitate passage of a knife blade 78 (FIG. 4). During operation of surgical stapler 10, drive assembly 212 abuts actuation sled 74 and pushes actuation sled 74 through longitudinal slots 70 of staple cartridge 54 to advance cam wedges 72 into sequential contact with pushers 68. Pushers 68 translate vertically along cam wedges 72 within fastener retention slots 64 and urge fasteners 66 from retention slots 64 into staple deforming cavities 30 (FIG. 4) of anvil assembly 20.

[0054] Referring to FIG. 3, mounting assembly 235 includes an upper mounting portion 236 and a lower mounting portion 238. A centrally located pivot member 284 extends from upper mounting portion 236 through a respective opening 246a formed in a first coupling member 246. Lower mounting portion 238 includes a bore 239 for receiving pivot member 284 (see FIG. 3F). Pivot member 284 extends through bore 239 and opening 247a of a second coupling member 247. Each of coupling members 246, 247 includes an interlocking proximal portion 246b, 247b configured to be received in grooves 290 formed in the distal end of an inner housing which is formed from upper and lower housing halves 250 and 252. Coupling members 246, 247 retain mounting assembly 235 and upper and lower housing halves 250 and 252 in a longitudinally fixed position in relation to each other while permitting pivotal movement of mounting assembly 235 in relation thereto.

[0055] Referring to FIGS. 3A-3C, each coupling member 246, 247 includes a cantilevered spring arm 246c which has a distal end 246d positioned to engage mounting assembly 235. More specifically, upper mounting portion 236 includes a top surface 236a which includes a recess 236b dimen-

sioned to receive distal end 246d of spring arm 246c of a respective coupling member 246. Lower mounting portion 238 includes a bottom surface 238a having a pair of raised surfaces 238b which define a recess 238c which is dimensioned to receive spring arm 247c of a respective coupling member 247. Alternatively, at least one recess may be formed in the proximal end of tool assembly 17.

[0056] As illustrated in FIGS. 3D-3G, when distal end of spring arms 246c, 247c of coupling members 246, 247 are positioned in recesses 236b and 238c of upper and lower mounting portions 236 and 238, respectively, spring arms 246c, 247c retain mounting assembly 235 in a non-articulated position. Spring arms 246c, 247c will retain mounting assembly 235 in its non-articulated position until a predetermined force sufficient to deflect spring arms 246c from recesses 236b and 238c is applied to effect articulation of mounting assembly 235 and tool assembly 17. When the predetermined force is applied to the mounting assembly 235 and tool assembly 17, spring arms 246c, 247c will spring or deflect outwardly from recesses 236b and 238c, as shown in FIGS. 3E and 3G, to permit pivotal movement of mounting assembly 235 (and, thus, tool assembly 17) in relation to the distal end of proximal body portion 200 of the DLU 16.

[0057] As discussed above, spring arms 246c and recesses 236b and 238c maintain tool assembly 17 in its non-articulated position until a predetermined force has been applied to mounting assembly 235 to disengage spring arms 246c, 247c from recesses 236b and 238c of mounting assembly 235. It is envisioned that the spring arms/recesses could be incorporated into any articulating surgical device including staplers, graspers (See FIG. 3H), powered sealing devices, e.g., RF sealing devices, etc. Further, although two spring arms/recesses are shown, a single spring arm can be provided. Moreover, the articulating tool assembly need not form part of a DLU but rather can be supported directly on the distal end of a surgical instrument. For example, the mounting assembly can be removably or irremovably secured to the tool assembly and secured directly to the distal end of a surgical instrument.

[0058] Upper housing half 250 and lower housing half 252 are contained within an outer sleeve 251 of body portion 200 (FIG. 3). Body portion 200 includes a cutout 251a dimensioned to receive a boss or projection 250a formed on upper housing half 250. The positioning of projection 250a within cutout 251a prevents axial and rotational movement of upper and lower housing halves 250 and 252 within outer sleeve 251 of body portion 200. In one embodiment, boss 250a has a substantially rectangular configuration having a greater axial dimension than lateral dimension. The greater axial dimension provides increased surface area for preventing rotation of upper and lower housing halves 250 and 252 within sleeve 251. A proximal portion 250b of boss 250a is ramped. Ramped proximal portion 250b allows sleeve 251 to be slid over boss 250a as upper and lower housing halves 250 and 252 are positioned within sleeve 251. It is envisioned that boss 250a may assume other configurations, e.g., circular, square, triangular, etc., and still achieve its intended function. Further, boss 250a can be repositioned anywhere along upper housing half 250 or, in the alternative, be positioned on lower housing half 252 or partly on each housing half 250 and 252.

[0059] The proximal end or insertion tip 193 of upper housing half 250 includes engagement nubs 254 for releas-

ably engaging the distal end of a surgical instrument in a bayonet-type fashion (see FIGS. 1A and 7). Housing halves 250 and 252 define a channel 400 for slidably receiving axial drive assembly 212 therein. An articulation link 256 is dimensioned to be slidably positioned within a slot 402 formed between upper and lower housing halves 250 and 252. A pair of H-block assemblies 255 are positioned adjacent the distal end of housing portion 200 and adjacent the distal end of axial drive assembly 212 to prevent outward buckling and bulging of drive assembly 212 during articulation and firing of surgical stapling apparatus 10. Each H-block assembly 255 includes a flexible body 255a which includes a proximal end fixedly secured to body portion 200 and a distal end fixedly secured to mounting assembly 235 (FIG. 3).

[0060] A retention member 288 is supported on engagement section 270 of axial drive assembly 212. Retention member 288 includes a pair of fingers 288a which are releasably positioned within slots or recesses 252a formed in lower housing half 252. In operation, when SULU 16 is attached to a surgical instrument and axial drive assembly 212 is actuated by applying a predetermined force to an actuation member 516 of the surgical instrument 500 (FIG. 11), axial drive assembly 212 is advanced distally to move drive assembly 212 and retention member 288 distally. As retention member 288 is advanced distally, fingers 288a are forced from recesses 252a to provide an audible and tactile indication that the surgical instrument has been actuated. Retention member 288 is designed to prevent inadvertent partial actuation of DLU 16, such as during shipping, by maintaining axial drive assembly 212 at a fixed position within DLU 16 until a predetermined axial force has been applied to axial drive assembly 212.

[0061] Axial drive assembly 212 includes an elongated drive beam 266 including a distal working head 268 and a proximal engagement section 270. In one embodiment, drive beam 266 is constructed from multiple stacked sheets of material. Engagement section 270 includes a pair of resilient engagement fingers 270a and 270b which mountingly engage a pair of corresponding retention slots formed in drive member 272. Drive member 272 includes a proximal porthole 274 configured to receive distal end of a control rod 520 (FIG. 11) of a surgical instrument when the proximal end of DLU 16 is engaged with the body portion 512 of a surgical instrument 500.

[0062] Referring also to FIGS. 5-10, DLU 16 further includes a locking mechanism including a locking member 300 and a locking member actuator 302. Locking member 300 (FIG. 6) is rotatably supported within a longitudinal or axial slot 310 (FIG. 7) formed in a proximal portion of upper housing half 250 of body portion 200 of DLU 16. Locking member 300 is movable from a first position (FIGS. 7 and 8), in which locking member 300 maintains drive assembly 212 in a prefired position, to a second position (FIGS. 9 and 10), in which drive assembly 212 is free to move axially.

[0063] As illustrated in FIG. 6, locking member 300 includes semi-cylindrical body 312 which is slidably positioned within transverse slot 310 formed in upper housing half 250 of body portion 200. Body 312 includes a radially inwardly extending cam member 314 and a radially inwardly extending finger 316. Finger 316 is dimensioned to be slidably received within a notch or slot 270c (FIG. 3) formed in drive assembly 212. Engagement of finger 316 in notch 270c of drive assembly 212 prevents drive assembly

212 from moving linearly within body portion 200 and, thus, prevents actuation of DLU 16.

[0064] Referring to FIGS. 3, 5 and 7, a locking member actuator 302 is slidably positioned within an axial slot 320 (FIG. 7) formed in upper housing half 250 of body portion 200 of DLU 16. Actuator 302 includes a proximal abutment member 322, a distal spring guide 324, and a central cam slot 326. Axial slot 320 intersects transverse slot 310 such that cam member 314 of locking member 300 is slidably positioned within cam slot 326 of locking member actuator 302. A biasing member or spring 328 (FIG. 7) is positioned about spring guide 324 between a distal surface 330 of actuator 302 and a wall 332 (FIG. 7) defining the distal end of axial slot 320. Spring 328 urges actuator 302 to its retracted position within axial slot 320. In its retracted position, abutment member 322 is positioned on and extends radially outwardly of the proximal end of DLU 16 adjacent insertion tip 193 of proximal body portion 200 and cam slot 326 is positioned to locate cam member 314 such that finger 316 of lock member 300 is positioned within notch 270c of drive assembly 212.

[0065] FIGS. 11-15 illustrate DLU 16 and surgical instrument 500 prior to and during attachment of DLU 16 to surgical instrument 500. Prior to attachment of DLU 16 onto surgical instrument 500, spring 328 urges actuator 302 to its retracted position to move lock member 300 to its locked position as discussed above. When insertion tip 193 DLU 16 is linearly inserted into the open end 522 (FIG. 11) of the body portion 512 (FIG. 13) of a surgical instrument 500, nubs 254 move linearly through slots (not shown) formed in open end 522 of body portion 512. As nubs 254 pass through the slots, the proximal end 322a of abutment member 322, which is angularly offset from nubs 254, abuts a wall 276c defining the slots for receiving nubs 254. As DLU 16 is moved further into body portion 512, locking member actuator 302 is moved from its retracted position to its advanced position in the direction indicated by arrow "T" in FIG. 14. As actuator 302 is moved to its advanced position, lock member 300 is cammed in the direction indicated by arrow "U" in FIG. 14 from its locked position (FIG. 8) engaged with drive assembly 212 to its unlocked position (FIG. 10) to move finger 316 from notch 270c. The locking mechanism including locking member 300 and locking member actuator 302 prevents accidental or inadvertent advancement or manipulation of the drive member of DLU 16 such as during loading of DLU 16 onto a surgical instrument 500.

[0066] When DLU 16 has been moved linearly in relation to instrument 500 to a position wherein a proximal surface 530 of body portion 200 abuts inner surface 276c of body portion 512 (FIG. 15), DLU 16 can be rotated in relation to body portion 512 in a bayonet-type action to position nubs 254 within openings 536 of body portion 512 to lock DLU 16 onto body portion 512. It is envisioned that other coupling types besides bayonet couplings may be used to connect DLU 16 to instrument 500, e.g., spring detent or snap-fit couplings, friction fit couplings, interlocking members, threaded couplings etc.

[0067] In an embodiment of the present disclosure illustrated in FIGS. 16-20, a locking assembly 600 is illustrated for use with surgical instrument 500 and disposable loading unit 16 (see FIG. 1, for example). In the illustrated embodiments, locking assembly 600 includes a housing 602, a pusher 604, a rod 606, a slide 608, at least one spring 610,

a cam finger 612, a pivot plate 614 having slots 616 and a link 618. Locking assembly 600 generally helps tool assembly 17 (see FIG. 1, for example) maintain its position during firing of surgical instrument 500.

[0068] Referring to FIGS. 16 and 17, a portion of locking assembly 600 is at least partially contained within a housing 602. FIG. 16 illustrates locking assembly 600 disposed in relation to housing 602, while FIG. 17 illustrates locking assembly 600 isolated from housing 602. In the illustrated embodiment of FIG. 17, pusher 604 is shown with rod 606 extending distally therefrom. Slide 608 extends distally from rod 606 and is in a slidable relationship therewith, thus allowing slide 608 to move axially with respect to rod 606. Spring 610 or pair of springs (not explicitly shown in this embodiment) distally biases slide 608 from rod 606.

[0069] Now referring to FIGS. 18-20, cam finger 612 and pivot plate 614 are illustrated. Cam finger 612 extends distally from slide 608 and pivot plate 614 may be disposed on mounting assembly 235 (see FIG. 3), for example. It is envisioned that pivot plate 614 may be disposed on or incorporated with a portion of tool assembly 17. A plurality of slots 616 (five slots 616 are illustrated) is disposed on pivot plate 614 and are sized to accept at least a portion of cam finger 612 therein. Upon different amounts of articulation of tool assembly 17 (including no substantial articulation) with respect to body portion 512 (see FIG. 1, for example), cam finger 612 is approximately aligned with an individual slot 616 of pivot plate 614. FIGS. 18 and 19 illustrate cam finger 612 substantially aligned with a center slot 616a (hidden from view in FIG. 19) and FIG. 20 illustrates cam finger 612 substantially aligned with a side slot 616b.

[0070] Link 618, illustrated in FIGS. 17 and 19, is in mechanical engagement with pivot plate 614 and cam finger 612. (In FIG. 18, the link has been removed.) Link 618 is illustrated having an opening 620 and a slot 622 (FIG. 19). Opening 620 is in a pivotal relationship with a boss 624 on pivot plate 614 and slot 622 is slidably engaged with cam finger 612. This relationship allows for articulation of pivot plate 614 with respect to body portion 512 and for longitudinal translation of slide 608 with respect to pivot plate 614.

[0071] In operation, upon at least a partial actuation of movable handle 516 (see FIG. 1, for example), pusher 604 is forced distally, e.g., via control rod 520 (see FIG. 11, for example), thus causing distal translation of cam finger 612 at least partially into a slot 616 of pivot plate 614. It is envisioned that actuating movable handle 516 to approximate cartridge assembly 18 and an anvil assembly 20 (see FIG. 1A, for example) also functions to translate cam finger 612 distally. In such an embodiment, when articulating tool assembly 17 is in place and clamped on tissue, further articulation cannot be accomplished (without releasing movable handle 516, for example). Thus, locking assembly 600 helps maintain articulating tool assembly 17 in position with respect to body portion 512, prior to emplacing staples into tissue, for example.

[0072] As discussed above, spring 610 distally biases slide 608 from rod 606. This biasing provided by spring 610 helps ensure cam finger 612 is not accidentally or prematurely dislodged from slot 616 of pivot plate 614, which may result in a significant amount of "play" therebetween. Additionally, the distal bias provided by spring 610 helps eliminate manufacturing tolerances and/or clearances that are present between slide 608 and pivot plate 614. It is also envisioned

that at least a portion of cam finger 612 and/or slot 616 may be wedge-shaped to help reduce any unintended movement therebetween. In such an embodiment, a distal portion of cam finger 612 and slot 616 would be narrower than a corresponding proximal portion.

[0073] In an embodiment of the present disclosure illustrated in FIGS. 21 and 22, a locking assembly 700 is illustrated for use with surgical instrument 500 and disposable loading unit 16 (see FIG. 1, for example). In the illustrated embodiment, locking assembly 700 includes an adapter 702, a pusher 704, a pivot 706, a biasing element (e.g., a pair of springs 708) and a link 710. Locking assembly 700 generally helps maintain tool assembly 17 in a predetermined position.

[0074] With reference to FIG. 21, adapter 702 of locking assembly 700 is generally housed within body portion 512 (see FIG. 1, for example) of surgical instrument 500 or within disposable loading unit 16. In the illustrated embodiment, pusher 704 is located distally of a pair of springs 708. Pusher 704 is distally biased via the pair of springs 708 towards pivot 706 of articulating tool assembly 17. A distal portion of pusher 704 includes a pusher mating surface 712 (FIG. 22) which is shaped and dimensioned to mate with a pivot mating surface 714 (FIG. 22) disposed adjacent a proximal portion of pivot 706. Link 710 is illustrated in mechanical cooperation with a portion of pusher 704 and pivotably connected to a portion of pivot 706, thus allowing articulating tool assembly 17 to move between its first position and its second position with respect to body portion 512. More specifically, link 710 includes an opening 711 that fits over a protrusion 707 of pivot 706, thus allowing pivotal movement therebetween. Further, link 710 is slidably engaged with a portion of adapter 702, thus allowing longitudinal movement therebetween.

[0075] Now referring to FIG. 22, pusher mating surface 712 is substantially flat along a majority of its length in this embodiment. Correspondingly, pivot mating surface 714 is also flat along a majority of its length in the illustrated embodiment. Thus, the distal bias of pusher 704 towards pivot 706 (in the direction of arrow A) via the pair of springs 708, helps maintain articulating tool assembly 17 in its first, non-articulated, position, as the biasing force helps articulating tool assembly 17 resist pivoting. While two springs 708 are illustrated, more or fewer springs 708 may be provided.

[0076] To pivot articulating tool 17 from its first, non-articulated position, the distal biasing force from pair of springs 708 must be overcome. Such a pivoting action, moves pusher 704 proximally (in the direction of arrow B) against the bias of pair of springs 708. It is also envisioned that pusher mating surface 714 includes detents (not explicitly shown in this embodiment) to help stabilize articulating jaw member 17 in selected articulated positions.

[0077] With continued reference to FIG. 22, pivot 706 includes a shelf 716 thereon. As shown in FIG. 22, shelf 716 overlaps at least a portion of pusher 704 when pusher mating surface 712 is in contact with pivot mating surface 714. Shelf 716 is situated and configured to help prevent tissue from being pinched between pusher 704 and pivot 706 when articulating tool assembly 17 is rotated and/or articulated.

[0078] In an embodiment of the present disclosure illustrated in FIGS. 23-25, a multi-layered drive beam 750 having a plurality of layers 750a-750e is illustrated and may be included in a disposable loading unit 16 (see FIG. 1, for

example). A closure apparatus **760**, such as an I-beam, is also illustrated. Closure apparatus **760** includes a horizontal portion **762** that is advanceable into camming surface **42** (or other contact surface) to approximate tool assembly tool **17**, as described in detail above with reference to FIG. 2.

[0079] With reference to FIG. 24, multi-layered drive beam **750** having five layers **750a-750e** is illustrated. It is envisioned and within the scope of the present disclosure that fewer or more layers may be used to form multi-layered drive beam **750**. It is also envisioned that multi-layered drive beam **750** may replace drive beam **266** in other embodiments of this disclosure. Use of multi-layered drive beam **750** may provide increased strength and flexibility during use, specifically, for instance, while tool assembly **17** is in an articulated position.

[0080] A plurality of cutouts **770** is illustrated in FIGS. 23-25 which extend through each layer of multi-layered drive beam **750**. Although the figures show between five and ten cutouts per layer of multi-layered drive beam **750**, the exact number of cutouts **770** may be fewer than five, between five and ten, or greater than ten. Additionally, cutouts **770** of adjacent layers of drive beam **750** may or not align with each other. The use of cutouts **770** reduces cross-sectional dimensions of drive beam **750** and allows for bending force adjustment. While rectangular cutouts **770** are illustrated, the use of cutouts **770** having other regular or non-regular shapes is also contemplated.

[0081] The attachment of each layer **750a-750e** of multi-layered drive beam **750** and the attachment to closure apparatus **760** are illustrated in FIG. 25. In the illustrated embodiment, an outer layer (**750a** or **750e** of FIG. 24) is affixed to closure apparatus **760** in two locations (each location being indicated by numeral **780** in FIG. 25), via a pair of spot welds, for example. It is also envisioned that each outer layer **750a**, **750e** includes an aperture **776** that fits over a boss **778** protruding from closure apparatus **760**. Each outer layer **750a**, **750e** is also affixed to an adjacent layer (e.g., **750b** or **750d**) in two locations (each location being indicated by numeral **781** in FIG. 25), possibly via a pair of spot welds. Further, each inner layer (e.g., **750b**, **750c** and **750d**) is attached to an adjacent inner layer (for instance, **750b** is attached to **750c**; **750c** is attached to **750b** and **750d**; and **750d** is attached to **750c**) in two locations, via spot welds, for example. While spot welding is disclosed as an attachment method, other methods for attaching each layer to each other and the outer layers to the closure apparatus are envisioned and within the scope of the present disclosure. The illustrated embodiments show attachment points **780** of inner layers adjacent closure apparatus **760**, but it is envisioned and within the scope of the present disclosure that attachment points **780** are disposed in other locations on drive beam **750**. Additionally, it is envisioned that at least one layer of drive beam **750** is made of a metal, such as stainless steel. Portions of drive beam **750** and/or closure apparatus **760** may also be made of or at least partially coated with a plastic material, as described below. Further, closure apparatus **790** may include a cutting surface **766** (FIG. 23) thereon for cutting tissue.

[0082] In an embodiment of the present disclosure illustrated in FIGS. 26 and 27, a closure apparatus **800** and a portion of drive beam **802** are shown. Closure apparatus and/or a contact surface (e.g., camming surface **42**) of tool assembly **17** (see FIG. 2, for example) may include a plastic

surface or plastic coating. In this embodiment, closure apparatus **800** is illustrated having a pair of caps **804** at least partially covering horizontal portions **806** of closure apparatus **800**. Caps **804** may be made of plastic in this embodiment. Such plastic surfaces disposed on closure apparatus **800** and/or contact surface of tool assembly **17** generally reduce the amount of friction therebetween vis-à-vis two metal surfaces. That is, a plastic to metal or a plastic to plastic interaction may create less friction than interaction between a pair of metal surfaces. This reduced amount of friction may correspond to a reduced firing force.

[0083] It is envisioned that a portion of closure apparatus **800**, such as pair of caps **804**, is made of plastic, overmolded with plastic or includes a plastic coating. Additionally, a contact surface of tool assembly **17**, or at least a portion thereof, may also be made of plastic, be overmolded with plastic or include a plastic coating.

[0084] In an embodiment of the disclosure, closure apparatus **800** may include an I-shaped cross section, as illustrated in FIGS. 26 and 27. Additionally, closure apparatus **800** and drive beam **802** may be part of a disposable loading unit **16** and/or part of a surgical instrument **500** that is able to articulate. Further, drive beam **802** may include a single layer or a plurality of layers (as shown in FIG. 26) and at least a portion of drive beam **802** may be made of plastic. Still further, closure apparatus **800** may include a cutting surface **808** (FIG. 27) thereon for cutting tissue.

[0085] With continued reference to FIGS. 26 and 27, plastic cap **804** may include a reinforced section **810** which may increase the strength of closure apparatus **800** or may provide a stronger connection between cap **804** and horizontal portion **806** of closure apparatus **800**. It is also envisioned that cap **804** may be removably attached to closure apparatus **800**. In such an embodiment, cap **804** may be removed and replaced if any substantial wearing or damage occurs.

[0086] In an embodiment of the present disclosure illustrated in FIGS. 28 and 29, a tool assembly **850** is illustrated. Tool assembly **850** of this embodiment includes a channel **852**, a first attachment member **860**, a second attachment member **870**, an anvil assembly **880**, a first attachment rod **890** and a second attachment rod **892**. First and second attachment rods **890**, **892** provide a strong connection facilitating the elements of tool assembly **850** to remain together.

[0087] Channel **852** includes an opening **854** (two openings are illustrated) adjacent its proximal end and first attachment member **860** includes a boss **862** (two bosses are illustrated) extending therefrom. Channel **852** is connectable to first attachment member by placing opening(s) **854** over boss(es) **862**, thus providing a pivotal connection therebetween. Although not explicitly illustrated in the present embodiment, channel **852** may house a plurality of surgical fasteners or a staple cartridge.

[0088] Anvil assembly **880** includes an anvil cover **882** and an anvil **886**. Anvil **886** is configured for mechanical engagement with anvil cover **882**, e.g., via a snap-fit connection. An aperture **884** extends at least partially through a portion of anvil cover **882**. Aperture **884** is configured to fit over a protrusion **872** disposed on second attachment member **870**, thereby providing a connection between anvil assembly **880** and second attachment member **870**. Additionally, anvil cover **882** includes at least one opening **888** extending at least partially therethrough in an embodiment of the disclosure. Opening **888** is configured to fit over boss

862 of first attachment member **860**. In such an embodiment, anvil assembly **880** may be pivoted with respect to first attachment member **860** and second attachment member **870**.

[0089] First attachment member **860** includes a first opening **864** and a second opening **866** extending therethrough. Second attachment member **870** also includes a first opening **874** and a second opening **876** extending therethrough (FIG. 29). Further, first attachment member **860** and second attachment member **870** are in mechanical engagement, such that first openings **864**, **874** substantially align and second openings **866**, **876** substantially align.

[0090] To secure first attachment member **860** with second attachment member **870** (and thus channel **852** and anvil assembly **880**), first attachment rod **890**, or a portion thereof, is inserted through first openings **864** and **874**. To further secure the elements of tool assembly **850**, second attachment rod **892**, or a portion thereof, is inserted through second openings **866** and **876**. It is envisioned that first attachment rod **890** and/or second attachment rod **892** are rivets, such as two-part rivets that are tightenable.

[0091] In an embodiment of the disclosure, tool assembly **850** is part of a disposable loading unit, which may be able to articulate. Articulation of tool assembly **850** may be facilitated by pivotably attaching tool assembly **850** to a body portion of a surgical instrument via protrusion **874** extending from second attachment member **870** and a link (such as link **710** in FIG. 21). Additionally, a method of assembling tool assembly **850**, as described above, is contemplated by the present disclosure.

[0092] It will be understood that various modifications may be made to the embodiments disclosed herein. For example, the above-described lock assembly may be incorporated into a variety of surgical instruments which include DLUs and is not limited to use on linear staplers. Further, the DLU may be configured to receive an insertion tip of surgical instrument in contrast to that disclosed. Therefore, the above description should not be construed as limiting, but merely as exemplifications of various embodiments. Those skilled in the art will envision other modifications within the scope and spirit of the claims appended hereto.

What is claimed is:

1. A surgical instrument, comprising:
 - a handle portion including a movable handle;
 - a body portion extending distally from the handle portion and defining a first longitudinal axis;
 - an articulating tool assembly defining a second longitudinal axis, the articulating tool assembly being disposed at a distal end of the body portion and being movable from a first position in which the second longitudinal axis is substantially aligned with the first longitudinal axis to at least a second position in which the second longitudinal axis is disposed at an angle to the first longitudinal axis;
 - the articulating tool assembly including an anvil and a cartridge assembly, the anvil and cartridge assembly being movable into approximation with one another by manipulation of the movable handle; and
 - a locking assembly including a member advanceable distally with respect to the body portion, the member engaging the articulating tool assembly upon manipulation of the movable handle to move the anvil and

cartridge assembly in approximation with one another to help maintain the articulating tool assembly in its first position.

2. The surgical instrument of claim 1, wherein the locking assembly includes a pivot plate in mechanical cooperation with the articulating tool assembly and the member is a finger in mechanical cooperation with the body portion.

3. The surgical instrument of claim 2, wherein the pivot plate has at least one slot therein and being securable to a portion of the articulating tool assembly, the finger extending distally from a portion of the body portion and being engagable with the at least one slot.

4. The surgical instrument of claim 3, wherein at least a partial actuation of the movable handle causes the finger to move towards the at least one slot.

5. The surgical instrument of claim 1, wherein the pivot plate includes five slots.

6. The surgical instrument of claim 1, wherein the locking assembly further includes at least one biasing element which biases the member distally towards the pivot plate.

7. The surgical instrument of claim 6, wherein the biasing element includes at least one spring.

8. The surgical instrument of claim 1, wherein at least one of the member and the at least one slot is at least partially wedge-shaped.

9. The surgical instrument of claim 1, wherein the locking assembly further includes a link, the link being in mechanical engagement with the pivot plate and the member.

10. The surgical instrument of claim 9, wherein the link is pivotably engagable with the pivot plate and is slidable with respect to the member.

11. The surgical instrument of claim 1, wherein the articulating tool assembly is part of a disposable loading unit.

12. A disposable loading unit configured for releasable engagement with a surgical instrument, comprising:

- a body portion and defining a first longitudinal axis;
- an articulating tool assembly disposed distally of the body portion being securable to a distal end of the body portion and defining a second longitudinal axis, the articulating tool assembly being movable from a first position in which the second longitudinal axis is substantially aligned with the first longitudinal axis to a second position in which the second longitudinal axis is disposed at an angle to the first longitudinal axis; and
- a locking assembly including a pivot plate in mechanical cooperation with the articulating tool assembly and a finger in mechanical cooperation with the body portion, the pivot plate having at least one slot therein and being securable to a portion of the articulating tool assembly, the finger extending distally from a portion of the body portion and being engagable with the at least one slot, whereby a predetermined amount of distal movement of the finger with respect to the pivot plate advances the finger at least partially into engagement with the at least one slot to help maintain the articulating tool assembly in its first position.

13. The disposable loading unit of claim 12, wherein the pivot plate includes five slots.

14. The disposable loading unit of claim 12, wherein the locking assembly further includes at least one biasing element which biases the finger distally towards the pivot plate.

15. The disposable loading unit of claim 14, wherein the biasing element includes at least one spring.

16. The disposable loading unit of claim **12**, wherein at least one of the finger and the at least one slot is at least partially wedge-shaped.

17. The disposable loading unit of claim **12**, wherein the locking assembly further includes a link, the link being in mechanical engagement with the pivot plate and the finger.

18. The disposable loading unit of claim **17**, wherein the link is in pivotable engagement with the pivot plate and is slidable with respect to the finger.
