TITLE OF THE INVENTION

1-SUBSTITUTED 4-ARYLPIPERAZINES AS KAPPA OPIOID RECEPTOR ANTAGONISTS

REFERENCE TO PREVIOUS APPLICATIONS

This application claims benefit to U.S. Provisional Application Serial No. 61/568,961 filed on December 9, 2011, and incorporated herein by reference.

STATEMENT OF FEDERAL SUPPORT

This invention was made with government support under grant number 2R01DA009045 awarded by the NIH. The government has certain rights in the invention.

BACKGROUND OF THE INVENTION

FIELD OF THE INVENTION

The present invention relates to arylpiperazine compounds which function as opioid receptor antagonists and can be used to treat a variety of disease states.

DESCRIPTION OF THE BACKGROUND

The opioid receptors, µ, δ, κ, and the opioid-like receptor ORL-1 belong to the super family of G-protein coupled receptors (GPCRs) that possess seven helical trans-membrane spanning domains in their architecture. The majority of research efforts focused upon this group of proteins has been directed toward the µ receptor since it mediates the actions of both the opiate and opioid analgesics such as morphine and fentanyl, respectively. However, over the years it has become increasingly clear that the entire family of proteins is actively involved in a host of biological processes. Furthermore, the advent of selective antagonists has demonstrated that pharmacotherapeutic opportunities exist via both negative and positive modulation of this receptor family.

The opioid receptor system has been extensively studied, and thousands of compounds have been synthesized and evaluated by in vitro binding and functional assays as well as by animal models. An integral part of the effort to characterize the opioid receptor system has been the discovery of potent, pure antagonists. Naloxone (la) and naltrexone (lb), both
competitive antagonists at µ, δ, and κ opioid receptors, have been extensively used as pharmacological tools to identify and characterize opioid systems. Additionally, naloxone is approved to treat heroin overdose and to reverse respiratory depression caused by morphine. Naltrexone is used to treat heroin and alcohol abuse.

In 1978, Zimmerman and co-workers reported the discovery of a structurally unique series of opioid receptor pure antagonists based on N-substituted analogues of 3,4-dimethyl-4-(3-hydroxyphenyl)piperidine (2a, LY272922). Unlike naloxone (la) and naltrexone (lb) where the antagonist activity is dependent on the N-allyl or N-cyclopropylmethyl substituent, all N-substituted trans-3,4-dimethyl-4-(3-hydroxyphenyl)piperidines (2) including the N-methyl analogue 2b are opioid receptor pure antagonists. A few of the more interesting analogues include alvimopan (3), which is an FDA-approved drug for GI motility disorder, LY255,582 (2d), which was developed to treat obesity, and the selective κ opioid receptor antagonist JDTic (4), which shows activity in rat models of depression, anxiety, and stress-induced cocaine relapse. All preclinical studies for JDTic have been completed, and phase 1 clinical studies are underway.

Previous work led to the discovery of 3-(4-substituted piperazin-1-yl)phenols (5) as a new class of opioid receptor antagonists and submitted two patent applications to cover this class of novel opioid receptor antagonist. These studies are presented in a recent publication. These compounds are relatively nonselective opioid receptor antagonists. Thus, their opioid receptor properties are more like those of naloxone (la), naltrexone (lb), and the originally reported N-substituted 3,4-dimethyl-4-(3-hydroxyphenyl)piperidines.

Previously, the opiate class, represented by naloxone (la), naltrexone (lb), and the N-substituted 3,4-dimethyl-4-(3-hydroxyphenyl)piperidines, represented by alvimopan, LY255,582, and JDTic, were the only two classes of nonpeptide pure opioid receptor antagonists known. The discovery that 3-(4-substituted piperazin-1-yl)phenols (5) are pure opioid receptor antagonists added a third example of this important class of compounds.

More recently, AZ-MTAB, PF-4455242, and LY2456302 have been reported as selective κ opioid receptor antagonists. These compounds have a very different structure as compared to the compounds discussed above.
Studies with selective κ opioid antagonists have shown that this system is intimately involved in brain processes that relate to stress, fear, and anxiety as well as reward-seeking behavior. Studies have shown that JDTic (4) and nor-BNI, another κ opioid selective antagonist, dose-dependently reduce fear and stress-induced responses in multiple behavioral paradigms with rodents (immobility in the forced-swim assay,
18\textsuperscript{24} reduction of exploratory behavior in the elevated plus maze, and fear-potentiated startle).\textsuperscript{19} Furthermore, selective κ antagonists have been shown to reduce stress-induced reinstatement of cocaine self-administration in rats,\textsuperscript{18} to block the stress-induced potentiation of cocaine place preference.
conditioning, to decrease dependence-induced ethanol self-administration, to diminish deprivation-induced eating in rats, and to prevent pre-pulse inhibition mediated by U50,488. These observations regarding the behavioral consequences of receptor blockade in several animal tests suggest that κ antagonists will be useful for treating anxiety, depression, schizophrenia, addiction, and eating disorders.

Previously reported non-selective opioid receptor antagonists such as LY255582 have been found to increase metabolic energy consumption and reduce the weight in obese rats while maintaining muscle mass. These reports suggest that opioid receptor antagonists may be useful in preventing, treating, and/or ameliorating the effect of obesity. Eli Lilly and Company has developed new classes of opioid receptor antagonists that interact with the µ, δ, and κ receptors (termed non-selective) as potential pharmacotherapies to treat obesity and related diseases. The Lilly patents suggest that their compounds will be useful for the treatment and/or prophylaxis of obesity and related diseases including eating disorders (bulimia, anorexia nervosa, etc.), diabetes, diabetic complications, diabetic retinopathy, sexual/reproductive disorders, depression, anxiety, epileptic seizure, hypertension, cerebral hemorrhage, congestive heart failure, sleeping disorders, atherosclerosis, rheumatoid arthritis, stroke, hyperlipidemia, hypertriglyceridemia, hyperglycemia, hyperlipoproteinemia, substance abuse, drug overdose, compulsive behavior disorders (such as paw licking in dog), and addictive behaviors such as for example gambling and alcoholism.

In view of the foregoing, there remains a need for improved agents which bind at opioid receptors. There is a particular need for potent and selective κ opioid receptor antagonists relative to the µ and δ opioid receptors.

SUMMARY OF THE INVENTION

The invention described herein is based on the discovery of potent and selective κ opioid receptor antagonist activity with substituted 3-(4-substituted piperazin-1-yl)phenols. Such compounds have remarkably higher affinity for the κ receptor as compared to either the µ receptor or the δ receptor. This heightened selectivity for the κ receptor is particularly significant.

As noted above, the ring to which W is attached may contain one nitrogen in the ring, represented by A or B. However, only one of A and B may be nitrogen. Additionally, the present compounds can be used in the treatment of Parkinson's disease as an adjunct to L-dopa for treatment of dyskinesia associated with the L-dopa treatment.

The compounds of the present invention are particularly useful for treating addiction, such as addiction to cocaine, alcohol, methamphetamine, nicotine, heroin, and other drugs of abuse. With respect to nicotine, the compounds of the present invention are also useful in treating nicotine withdrawal effects.

The compounds may be administered in an effective amount by any of the conventional techniques well-established in the medical field. For example, the compounds may be administered orally, intravenously, or intramuscularly. When so administered, the inventive compounds may be combined with any of the well-known pharmaceutical carriers and additives that are customarily used in such pharmaceutical compositions. For a discussion of dosing forms, carriers, additives, pharmacodynamics, etc., see Kirk-Othmer Encyclopedia of Chemical Technology, Fourth Edition, Vol. 18, 1996, pp. 480-590, incorporated herein by reference. The patient is preferably a mammal, with human patients especially preferred. Effective amounts are readily determined by those of ordinary skill in the art. Studies by the present inventors show no toxicity and no lethality for the present compounds at amounts up to 300 mg/kg in mice.

The compounds of the present invention can be administered as a single dosage per day, or as multiple dosages per day. When administered as multiple dosages, the dosages can
be equal doses or doses of varying amount, based upon the time between the doses (i.e. when there will be a longer time between doses, such as overnight while sleeping, the dose administered will be higher to allow the compound to be present in the bloodstream of the patient for the longer period of time at effective levels). Preferably, the compound and compositions containing the compound are administered as a single dose or from 2-4 equal doses per day.

Suitable compositions containing the present compounds further comprise a physiologically acceptable carrier, such as water or conventional pharmaceutical solid carriers, and if desired, one or more buffers and other excipients.

**EXAMPLES**

Having generally described this invention, a further understanding can be obtained by reference to certain specific examples which are provided herein for purposes of illustration only and are not intended to be limiting unless otherwise specified.

The synthesis and activity of exemplary compounds of the present invention are described below.

**Scheme 1**

Reagents: (a) $K_2CO_3$ or KOH, DMF, 175 °C, sealed tube; (b) CrO$_3$, acetone, room temperature; (c) 48% HBr, AcOH, reflux.
The substituted 4-phenoxybenzoic acids lOa-lOm were synthesized in accordance with the reaction sequence, shown in Scheme 1. Phenols 8a-8g were allowed to react with 4-fluorobenzaldehyde, 4-fluoro-3-methylbenzaldehyde, or 3-chloro-4-fluorobenzaldehyde at high temperature in the presence of potassium carbonate or potassium hydroxide to yield diaryl ethers, which were oxidized with Jones reagent to the corresponding acids lOa-lOg, l0k and 10l. With the compounds where X, Y, or Z = OCH₃, treatment with refluxing 48% HBr yielded the corresponding hydroxy-substituted acids lOh-lOj and 10m.
Scheme 2

Reagents: (a) iodobenzene, copper dust, DMF, reflux; (b) mCPBA, CH₂Cl₂, room temperature; (c) Ac₂O, AcOH, 150 °C, sealed tube; (d) K₂CO₃, CH₃OH, H₂O, room temperature; (e) KMnO₄, acetone, 50 °C.

Acid 14 was synthesized by the route, shown in Scheme 2. The Ullmann ether condensation of pyridine 11 with iodobenzene, followed by oxidation with mCPBA yielded the pyridine N-oxide 12. Treatment of 12 with acetic anhydride at 150 °C in a sealed tube and hydrolysis of the resulting intermediate with potassium carbonate in aqueous methanol afforded alcohol 13. Oxidation of 13 with potassium permanganate provided acid 14.

Scheme 3

Acid 21 was prepared according to the sequence illustrated in Scheme 3. The methyl ester of 6-chloronicotinic acid was prepared using trimethylsilyldiazomethane in toluene and methanol. Nucleophilic aromatic substitution with phenol gave aryl ether 20, which upon saponification with lithium hydroxide yielded the desired carboxylic acid 21.
Scheme 4

Reagents: (a) N-Boc-L-valine, HBTU, Et$_3$N, CH$_3$CN, room temperature; (b) BH$_3$·THF, room temperature, then cone. HCl, reflux; (c) 4-phenoxybenzoic acid or 14, HBTU, Et$_3$N, CH$_3$CN, room temperature; (d) I0a-I0e, BOP, Et$_3$N, CH$_2$C$_4$H$_5$, room temperature; (e) I0f-I0j, or 14 or 21, EDC·HCl, Et$_3$N, CH$_2$C$_4$H$_5$, room temperature.

Compounds 6a-6m, 7a, and 7b were synthesized following the reaction sequence, outlined in Scheme 4. The starting piperazine 15 was synthesized according to the reported method. Coupling of 15 with N-Boc-L-valine using HBTU afforded amide 16, which was reduced with borane in THF, followed by HCl treatment, to give amine 17. Amine 17 was coupled with the appropriate acid using HBTU, BOP or EDC·HCl to yield target compounds 6a-6m, 7a, and 7b. Compounds 19a-p were synthesized by procedures similar to those used for the synthesis of 6a-m as outlined in Scheme 5.
Scheme 5

Biological Activity

Measures of opioid receptor antagonism and specificity were obtained by monitoring the ability of selected test compounds to inhibit stimulation of [35S]GTPyS binding produced by the selective agonists (D-Ala2,MePhe4,Gly-ol5)enkephalin (DAMGO, µ receptor) cyclo[D-Pen2,D-Pen5]enkephalin (DPDPE, δ) and 5,7,8-( - )-N-methyl-N-[7-(l-pyrrolidinyl)-l-oxaspiro[4,5]dec-8-yl]benzeneacetamide (U69,593, κ) in cloned human receptors. The data is presented in Table 1.

Compounds 6a-6m, 7a, and 7b as well as 19a-p show high efficacy (low K e values) for the κ opioid receptor in the [35S]GTPyS in vitro functional assay, particularly 6a, 6b, 6d, 6f, 6j, 6k, 6l, 19a, and 19c-j. In addition, 6a, 6d, 6h, 6l, 19e, 19g, and 19h have greater than 60 and 131 selectivity for the κ receptor relative to the µ and δ receptors.

The compounds of the present invention are potent κ opioid receptor antagonists in an in vitro functional test. Some of the compounds showed high selectivity for the κ relative to the µ and δ opioid receptors.

Experimental Procedures

Melting points were determined using a MEL-TEMP II capillary melting point apparatus and are uncorrected. Nuclear magnetic resonance (1H NMR and 13C NMR) spectra were obtained on a Bruker Avance DPX-300 MHz NMR spectrometer or a Varian Unity Inova 500 MHz NMR spectrometer. Chemical shifts are reported in parts per million (ppm) with reference to internal solvent. Mass spectra (MS) were run on a Perkin-Elmer Sciex API 150 EX mass spectrometer equipped with APCI (atmospheric pressure chemical ionization) or ESI (turbospray) sources or on a Hewlett Packard 5989A instrument by electron impact. Elemental analyses were performed by Atlantic Microlab Inc., Atlanta, GA. Optical rotations were measured on an AutoPol III polarimeter, purchased from Rudolf Research. Analytical thin-layer chromatography (TLC) was carried out using EMD silica gel 60 F254 TLC plates. TLC visualization was achieved with a UV lamp or in an iodine chamber. Flash column chromatography was done on a CombiFlash Companion system using Isco prepacked silica gel columns or using EM Science silica gel 60A (230–400 mesh). Solvent system: 80CMA = 80:18:2 CHCl3:MeOH:conc. NH4OH. Unless otherwise stated, reagent-grade chemicals were obtained from commercial sources and were used without further purification. All moisture- and air-sensitive reactions and reagent transfers were carried out under dry nitrogen.

General Procedures for the Preparation of 3-[4-(Substituted piperazin-1-yl)]-phenols (6a-6m, 7a, and 7b)

**General Procedure A**. The appropriate phenol (5.10 mmol) and KOH (5.10 mmol) were dissolved in DMF (3 mL) before the appropriate 4-fluorobenzaldehyde (5.00 mmol) was added. The solution was heated in a sealed tube to 175 °C for 20 min, poured into H2O (25 mL) and extracted with Et2O (75 mL). The organic layer was washed with H2O (25 mL), brine (10 mL) and dried (Na2SO4). The crude residue resulting from concentration was dissolved in acetone (25 mL) and treated with Jones reagent (3 mL, 0.1 M CrO3 in aqueous H2SO4). Upon completion by TLC, isopropanol (3 mL) was added and the reaction mixture was concentrated. The residue was dissolved in 5% aqueous NaOH, filtered, and the filtrate was acidified with 50% H2SO4 and extracted with EtOAc (3 × 25 mL). The combined EtOAc extracts were dried (Na2SO4) and concentrated to afford the desired substituted 4-phenoxybenzoic acid.

**General Procedure B**. To a solution of the appropriate acid (0.05 mmol) and BOP reagent (0.05 mmol) in CH2Cl2 (10 mL) was added piperazine 17 (0.05 mmol) in THF (2 mL)
and Et₃N (25 µL). After 12 h, the residue resulting from concentration was purified by flash column chromatography on silica gel using an EtOAc gradient in hexane. The residue from concentration of the combined desired fractions was dissolved in CH₂Cl₂ and treated with dry HCl in Et₂O. Removal of the solvent, followed by trituration of the residue with Et₂O yielded the desired product as the dihydrochloride salt.

**General Procedure C.** To a solution of the appropriate acid (0.12 mmol) and piperazine 17 (0.12 mmol) in CH₂Cl₂ (5 mL) was added HOBt (10 mol%), EDC·HCl (0.12 mmol) and Et₃N (40 µL). After 12 h, the residue resulting from concentration was purified by flash column chromatography on silica gel using an EtOAc gradient in hexane. The residue from concentration of the combined desired fractions was dissolved in CH₂Cl₂ and treated with dry HCl in Et₂O. Removal of the solvent, followed by trituration of the residue with Et₂O yielded the desired product as the dihydrochloride salt.
