## BETA-LACTAMASE INHIBITORS

[0001]

### FIELD OF INVENTION

[0002] The present invention relates to boron-containing compounds, compositions, preparations and their use as inhibitors of beta-lactamase enzymes and as antibacterial agents.

### BACKGROUND OF THE INVENTION

[0003] Antibiotics are the most effective drugs for curing bacteria-infectious diseases clinically. They have a wide market due to their advantages of good antibacterial effect with limited side effects. Among them, the beta-lactam class of antibiotics (for example, penicillins, cephalosporins, and carbapenems) are widely used because they have a strong bactericidal effect and low toxicity.

[0004] To counter the efficacy of the various beta-lactams, bacteria have evolved to produce variants of beta-lactam deactivating enzymes called beta-lactamases, and in the ability to share this tool inter- and intra-species. These beta-lactamases are categorized as “serine” or “metallo” based, respectively, on presence of a key serine or zinc in the enzyme active site. The rapid spread of this mechanism of bacterial resistance can severely limit beta-lactam treatment options in the hospital and in the community.

### SUMMARY OF THE INVENTION

[0005] Described herein are compounds that modulate the activity of beta-lactamases. In some embodiments, the compounds described herein inhibit beta-lactamases. In certain embodiments, the compounds described herein are useful in the treatment of bacterial infections.

[0006] In one aspect, provided herein are compounds of Formula I or Formula Ia, or pharmaceutically acceptable salts, solvates, polymorphs, stereoisomers, tautomers, prodrugs, metabolites, N-oxides, or isomers thereof:

[0021]

#### **DETAILED DESCRIPTION OF THE INVENTION**

[0022] Beta-lactamases are typically grouped into 4 classes: Ambler classes A, B, C, and D, based on their amino acid sequences. Enzymes in classes A, C, and D are active-site serine beta-lactamases, while class B enzymes are Zn-dependent. Newer generation cephalosporins and carbapenems were developed partly based on their ability to evade the deactivating effect of the early serine-based beta-lactamase variants. However, a recent surge in new versions of serine-based beta-lactamases—for example Class A Extended-Spectrum Beta-Lactamase (ESBL) enzymes, Class A carbapenemases (e.g. KPC-2), chromosomal and plasmid mediated Class C cephalosporinases (AmpC, CMY, etc.), and Class D oxacillinases—as well as Class B metallo-beta-lactamases (e.g. VIM, NDM) has begun to diminish the utility of the beta-lactam antibiotic family, including the more recent generation beta-lactam drugs, leading to a serious medical problem. Indeed the number of catalogued serine-based beta-lactamases has exploded from less than ten in the 1970s to over 750 variants.

[0023] The commercially available beta-lactamase inhibitors (clavulanic acid, sulbactam, tazobactam) were developed to address the beta-lactamases that were clinically relevant in the 1970s and 1980s (e.g. penicillinases). These beta-lactamase inhibitors are poorly active against the diversity of beta-lactamase enzymes (both serine- and metallo-based) now emerging clinically. In addition, these enzyme inhibitors are available only as fixed combinations with penicillin derivatives. No combinations with cephalosporins (or carbapenems) are clinically available. This fact, combined with the increased use of newer generation cephalosporins and carbapenems, is driving the selection and spread of the new beta-lactamase variants (ESBLs, carbapenemases, chromosomal and plasmid-mediated Class C, Class D oxacillinas, etc.). While maintaining good inhibitory activity against ESBLs, the legacy beta-lactamase inhibitors are largely ineffective against the new Class A and Class B carbapenemases, against the chromosomal and plasmid-mediated Class C cephalosporinases and against many of the Class D oxacillinas.

[0024] To address this growing therapeutic vulnerability, and because there are three major molecular classes of serine-based beta-lactamases, and one major class of metallo-beta-lactamases, and each of these classes contain significant numbers of beta-lactamase variants, we have identified an approach for developing novel beta-lactamase inhibitors with broad spectrum functionality. In particular, we have identified an approach for developing compounds that are active against both serine- and metallo-based beta-lactamase enzymes. Compounds of the current invention demonstrate potent activity across all four major classes of beta-lactamases.

[0025] The present invention is directed to certain boron-based compounds (boronic acids and cyclic boronic acid esters) which are beta-lactamase inhibitors and antibacterial compounds. The compounds and their pharmaceutically acceptable salts are useful alone and in combination with beta-lactam antibiotics for the treatment of bacterial infections, particularly antibiotic resistant bacterial infections. Some embodiments include compounds, compositions, pharmaceutical compositions, use and preparation thereof.

### **Definitions**

[0026] In the following description, certain specific details are set forth in order to provide a thorough understanding of various embodiments. However, one skilled in the art will understand that the invention may be practiced without these details. In other instances, well-known structures have not been shown or described in detail to avoid unnecessarily obscuring descriptions of the embodiments. Unless the context requires otherwise, throughout the specification and claims which follow, the word “comprise” and variations thereof, such as, “comprises” and “comprising” are to be construed in an open, inclusive sense, that is, as

“including, but not limited to.” Further, headings provided herein are for convenience only and do not interpret the scope or meaning of the claimed invention.

[0027] Reference throughout this specification to “one embodiment” or “an embodiment” means that a particular feature, structure or characteristic described in connection with the embodiment is included in at least one embodiment. Thus, the appearances of the phrases “in one embodiment” or “in an embodiment” in various places throughout this specification are not necessarily all referring to the same embodiment. Furthermore, the particular features, structures, or characteristics may be combined in any suitable manner in one or more embodiments. Also, as used in this specification and the appended claims, the singular forms “a,” “an,” and “the” include plural referents unless the content clearly dictates otherwise. It should also be noted that the term “or” is generally employed in its sense including “and/or” unless the content clearly dictates otherwise.

[0028] The term “antibiotic” refers to a compound or composition which decreases the viability of a microorganism, or which inhibits the growth or proliferation of a microorganism. The phrase “inhibits the growth or proliferation” means increasing the generation time (i.e., the time required for the bacterial cell to divide or for the population to double) by at least about 2-fold. Preferred antibiotics are those which can increase the generation time by at least about 10-fold or more (e.g., at least about 100-fold or even indefinitely, as in total cell death). As used in this disclosure, an antibiotic is further intended to include an antimicrobial, bacteriostatic, or bactericidal agent. Examples of antibiotics suitable for use with respect to the present invention include penicillins, cephalosporins and carbapenems.

[0029] The term “ $\beta$ -lactam antibiotic” refers to a compound with antibiotic properties that contains a  $\beta$ -lactam functionality. Non-limiting examples of  $\beta$ -lactam antibiotics useful with respect to the invention include penicillins, cephalosporins, penems, carbapenems, and monobactams.

[0030] The term “ $\beta$ -lactamase” denotes a protein capable of inactivating a  $\beta$ -lactam antibiotic. The  $\beta$ -lactamase can be an enzyme which catalyzes the hydrolysis of the  $\beta$ -lactam ring of a  $\beta$ -lactam antibiotic. Of particular interest herein are microbial  $\beta$ -lactamases. The  $\beta$ -lactamase may be, for example, a serine  $\beta$ -lactamase or a metallo- $\beta$ -lactamase.  $\beta$ -Lactamases of interest include those disclosed in an ongoing website that monitors beta-lactamase nomenclature and in Bush, K. and G. A. Jacoby. 2010. An updated functional classification of  $\beta$ -lactamases. *Antimicrob. Agents Chemother.* 54:969-976.  $\beta$ -Lactamases of particular interest herein include  $\beta$ -lactamases found in bacteria such as class A  $\beta$ -lactamases including the SHV, CTX-M and KPC subclasses, class B  $\beta$ -lactamases such as VIM, class C  $\beta$ -lactamases (both chromosomal and plasmid-mediated), and class D  $\beta$ -lactamases. The term “ $\beta$ -lactamase

inhibitor" refers to a compound which is capable of inhibiting  $\beta$ -lactamase activity. Inhibiting  $\beta$ -lactamase activity means inhibiting the activity of a class A, B, C, or D  $\beta$ -lactamase. For antimicrobial applications inhibition at a 50% inhibitory concentration is preferably achieved at or below about 100 micrograms/mL, or at or below about 50 micrograms/mL, or at or below about 25 micrograms/mL. The terms "class A", "class B", "class C", and "class D"  $\beta$ -lactamases are understood by those skilled in the art and are described in Bush, K. and G. A. Jacoby. 2010. An updated functional classification of  $\beta$ -lactamases. *Antimicrob. Agents Chemother.* 54:969-976.

Unless stated otherwise specifically in the specification, a heterocyclyl group may be optionally substituted. Illustrative examples of heterocycloalkyl groups, also referred to as non-aromatic heterocycles, include:

, and the like. The term heterocycloalkyl also includes all ring forms of the carbohydrates, including but not limited to the monosaccharides, the disaccharides and the oligosaccharides. Unless otherwise noted, heterocycloalkyls have from 2 to 10 carbons in the ring. It is understood that when referring to the number of carbon atoms in a heterocycloalkyl, the number of carbon atoms in the heterocycloalkyl is not the same as the total number of atoms (including the heteroatoms) that make up the heterocycloalkyl (i.e. skeletal atoms of the heterocycloalkyl ring). Unless stated otherwise specifically in the specification, a heterocycloalkyl group may be optionally substituted.

[0053] “Heteroaryl” refers to a 5- to 14-membered ring system radical comprising hydrogen atoms, one to thirteen carbon atoms, one to six heteroatoms selected from the group consisting

of nitrogen, oxygen, phosphorous and sulfur, and at least one aromatic ring. For purposes of this invention, the heteroaryl radical may be a monocyclic, bicyclic, tricyclic or tetracyclic ring system, which may include fused or bridged ring systems; and the nitrogen, carbon or sulfur atoms in the heteroaryl radical may be optionally oxidized; the nitrogen atom may be optionally quaternized. Examples include, but are not limited to, azepinyl, acridinyl, benzimidazolyl, benzothiazolyl, benzindolyl, benzodioxolyl, benzofuranyl, benzoazazolyl, benzothiazolyl, benzothiadiazolyl, benzo[*b*][1,4]dioxepinyl, 1,4-benzodioxanyl, benzonaphthofuranyl, benzoxazolyl, benzodioxolyl, benzodioxinyl, benzopyranyl, benzopyranonyl, benzofuranyl, benzofuranonyl, benzothienyl (benzothiophenyl), benzotriazolyl, benzo[4,6]imidazo[1,2-*a*]pyridinyl, carbazolyl, cinnolinyl, dibenzofuranyl, dibenzothiophenyl, furanyl, furanonyl, isothiazolyl, imidazolyl, indazolyl, indolyl, indazolyl, isoindolyl, indolinyl, isoindolinyl, isoquinolyl, indolizinyl, isoxazolyl, naphthyridinyl, oxadiazolyl, 2-oxoazepinyl, oxazolyl, oxiranyl, 1-oxidopyridinyl, 1-oxidopyrimidinyl, 1-oxidopyrazinyl, 1-oxidopyridazinyl, 1-phenyl-1*H*-pyrrolyl, phenazinyl, phenothiazinyl, phenoxazinyl, phthalazinyl, pteridinyl, purinyl, pyrrolyl, pyrazolyl, pyridinyl, pyrazinyl, pyrimidinyl, pyridazinyl, quinazolinyl, quinoxaliny, quinolinyl, quinuclidinyl, isoquinolinyl, tetrahydroquinolinyl, thiazolyl, thiadiazolyl, triazolyl, tetrazolyl, triazinyl, and thiophenyl (*i.e.*, thienyl). Unless stated otherwise specifically in the specification, a heteroaryl group may be optionally substituted.

**[0054]** All the above groups may be either substituted or unsubstituted. The term “substituted” as used herein means any of the above groups (*e.g.*, alkyl, alkylene, alkoxy, aryl, cycloalkyl, haloalkyl, heterocyclyl and/or heteroaryl) may be further functionalized wherein at least one hydrogen atom is replaced by a bond to a non-hydrogen atom substituent. Unless stated specifically in the specification, a substituted group may include one or more substituents selected from: oxo, amino, -CO<sub>2</sub>H, nitrile, nitro, hydroxyl, thiooxy, alkyl, alkylene, alkoxy, aryl, cycloalkyl, heterocyclyl, heteroaryl, dialkylamines, arylamines, alkylarylamines, diarylamines, trialkylammonium (-N<sup>+</sup>R<sub>3</sub>), N-oxides, imides, and enamines; a silicon atom in groups such as trialkylsilyl groups, dialkylarylsilyl groups, alkyldiarylsilyl groups, triarylsilyl groups, perfluoroalkyl or perfluoroalkoxy, for example, trifluoromethyl or trifluoromethoxy. “Substituted” also means any of the above groups in which one or more hydrogen atoms are replaced by a higher-order bond (*e.g.*, a double- or triple-bond) to a heteroatom such as oxygen in oxo, carbonyl, carboxyl, and ester groups; and nitrogen in groups such as imines, oximes, hydrazones, and nitriles. For example, “substituted” includes any of the above groups in which one or more hydrogen atoms are replaced with -NH<sub>2</sub>, -NR<sub>g</sub>C(=O)NR<sub>g</sub>R<sub>h</sub>, -NR<sub>g</sub>C(=O)OR<sub>h</sub>, -NR<sub>g</sub>SO<sub>2</sub>R<sub>h</sub>, -OC(=O)NR<sub>g</sub>R<sub>h</sub>, -OR<sub>g</sub>, -SR<sub>g</sub>, -SOR<sub>g</sub>, -SO<sub>2</sub>R<sub>g</sub>, -OSO<sub>2</sub>R<sub>g</sub>, -SO<sub>2</sub>OR<sub>g</sub>, =NSO<sub>2</sub>R<sub>g</sub>, and -SO<sub>2</sub>NR<sub>g</sub>R<sub>h</sub>. In the foregoing, R<sub>g</sub> and R<sub>h</sub> are the same or different and independently hydrogen,

alkyl, alkoxy, alkylamino, thioalkyl, aryl, aralkyl, cycloalkyl, cycloalkylalkyl, haloalkyl, heterocyclyl, *N*-heterocyclyl, heterocyclylalkyl, heteroaryl, *N*-heteroaryl and/or heteroarylalkyl. In addition, each of the foregoing substituents may also be optionally substituted with one or more of the above substituents. Furthermore, any of the above groups may be substituted to include one or more internal oxygen, sulfur, or nitrogen atoms. For example, an alkyl group may be substituted with one or more internal oxygen atoms to form an ether or polyether group. Similarly, an alkyl group may be substituted with one or more internal sulfur atoms to form a thioether, disulfide, etc.

**[0055]** The term “optional” or “optionally” means that the subsequently described event or circumstance may or may not occur, and that the description includes instances where said event or circumstance occurs and instances in which it does not. For example, “optionally substituted alkyl” means either “alkyl” or “substituted alkyl” as defined above. Further, an optionally substituted group may be un-substituted (e.g., -CH<sub>2</sub>CH<sub>3</sub>), fully substituted (e.g., -CF<sub>2</sub>CF<sub>3</sub>), mono-substituted (e.g., -CH<sub>2</sub>CH<sub>2</sub>F) or substituted at a level anywhere in-between fully substituted and mono-substituted (e.g., -CH<sub>2</sub>CHF<sub>2</sub>, -CH<sub>2</sub>CF<sub>3</sub>, -CF<sub>2</sub>CH<sub>3</sub>, -CFHCHF<sub>2</sub>, etc). It will be understood by those skilled in the art with respect to any group containing one or more substituents that such groups are not intended to introduce any substitution or substitution patterns (e.g., substituted alkyl includes optionally substituted cycloalkyl groups, which in turn are defined as including optionally substituted alkyl groups, potentially ad infinitum) that are sterically impractical and/or synthetically non-feasible. Thus, any substituents described should generally be understood as having a maximum molecular weight of about 1,000 daltons, and more typically, up to about 500 daltons.

**[0056]** An “effective amount” or “therapeutically effective amount” refers to an amount of a compound administered to a mammalian subject, either as a single dose or as part of a series of doses, which is effective to produce a desired therapeutic effect.

**[0057]** “Treatment” of an individual (e.g. a mammal, such as a human) or a cell is any type of intervention used in an attempt to alter the natural course of the individual or cell. In some embodiments, treatment includes administration of a pharmaceutical composition, subsequent to the initiation of a pathologic event or contact with an etiologic agent and includes stabilization of the condition (e.g., condition does not worsen) or alleviation of the condition. In other embodiments, treatment also includes prophylactic treatment (e.g., administration of a composition described herein when an individual is suspected to be suffering from a bacterial infection).

**[0058]** A “tautomer” refers to a proton shift from one atom of a molecule to another atom of the same molecule. The compounds presented herein may exist as tautomers. Tautomers are

compounds that are interconvertible by migration of a hydrogen atom, accompanied by a switch of a single bond and adjacent double bond. In bonding arrangements where tautomerization is possible, a chemical equilibrium of the tautomers will exist. All tautomeric forms of the compounds disclosed herein are contemplated. The exact ratio of the tautomers depends on several factors, including temperature, solvent, and pH. Some examples of tautomeric interconversions include:

[0059] A “metabolite” of a compound disclosed herein is a derivative of that compound that is formed when the compound is metabolized. The term “active metabolite” refers to a biologically active derivative of a compound that is formed when the compound is metabolized. The term “metabolized,” as used herein, refers to the sum of the processes (including, but not limited to, hydrolysis reactions and reactions catalyzed by enzymes, such as, oxidation reactions) by which a particular substance is changed by an organism. Thus, enzymes may produce specific structural alterations to a compound. For example, cytochrome P450 catalyzes a variety of oxidative and reductive reactions while uridine diphosphate glucuronyl transferases catalyze the transfer of an activated glucuronic-acid molecule to aromatic alcohols, aliphatic alcohols, carboxylic acids, amines and free sulfhydryl groups. Further information on metabolism may be obtained from *The Pharmacological Basis of Therapeutics*, 9th Edition, McGraw-Hill (1996). Metabolites of the compounds disclosed herein can be identified either by administration of compounds to a host and analysis of tissue samples from the host, or by incubation of compounds with hepatic cells in vitro and analysis of the resulting compounds. Both methods are well known in the art. In some embodiments, metabolites of a compound are formed by oxidative processes and correspond to the corresponding hydroxy-containing compound. In some embodiments, a compound is metabolized to pharmacologically active metabolites.

#### **Further Forms of Compounds Disclosed Herein**

##### **Isomers**

[0096] In some embodiments, due to the oxophilic nature of the boron atom, the compounds described herein may convert to or exist in equilibrium with alternate forms, particularly in milieu that contain water (aqueous solution, plasma, etc.). Accordingly, the compounds

described herein may exist in an equilibrium between the “closed” cyclic form shown in Formula I and the “open” acyclic form shown in Figure 1a. In addition the compounds described herein may associate into intramolecular dimers, trimers, and related combinations.

[0097] Furthermore, in some embodiments, the compounds described herein exist as geometric isomers. In some embodiments, the compounds described herein possess one or more double bonds. The compounds presented herein include all cis, trans, syn, anti, entgegen (E), and zusammen (Z) isomers as well as the corresponding mixtures thereof. In some situations, compounds exist as tautomers. The compounds described herein include all possible tautomers within the formulas described herein. In some situations, the compounds described herein possess one or more chiral centers and each center exists in the R configuration, or S configuration. The compounds described herein include all diastereomeric, enantiomeric, and epimeric forms as well as the corresponding mixtures thereof. In additional embodiments of the compounds and methods provided herein, mixtures of enantiomers and/or diastereoisomers, resulting from a single preparative step, combination, or interconversion are useful for the applications described herein. In some embodiments, the compounds described herein are prepared as their individual stereoisomers by reacting a racemic mixture of the compound with an optically active resolving agent to form a pair of diastereoisomeric compounds, separating the diastereomers and recovering the optically pure enantiomers. In some embodiments, dissociable complexes are preferred (e.g., crystalline diastereomeric salts). In some embodiments, the diastereomers have distinct physical properties (e.g., melting points, boiling points, solubilities, reactivity, etc.) and are separated by taking advantage of these dissimilarities. In some embodiments, the diastereomers are separated by chiral chromatography, or preferably, by separation/resolution techniques based upon differences in solubility. In some embodiments, the optically pure enantiomer is then recovered, along with the resolving agent, by any practical means that would not result in racemization.

**[00109]** Thus, the compounds described herein include all their crystalline forms, known as polymorphs. Polymorphs include the different crystal packing arrangements of the same elemental composition of a compound. In certain instances, polymorphs have different X-ray diffraction patterns, infrared spectra, melting points, density, hardness, crystal shape, optical and electrical properties, stability, and solubility. In certain instances, various factors such as the recrystallization solvent, rate of crystallization, and storage temperature cause a single crystal form to dominate.

## Prodrugs

[00110] In some embodiments, the compounds described herein exist in prodrug form. The invention provides for methods of treating diseases by administering such prodrugs. The invention further provides for methods of treating diseases by administering such prodrugs as pharmaceutical compositions.

[00111] Prodrugs are generally drug precursors that, following administration to an individual and subsequent absorption, are converted to an active, or a more active species via some process, such as conversion by a metabolic pathway. Some prodrugs have a chemical group present on the prodrug that renders it less active and/or confers solubility or some other property to the drug. Once the chemical group has been cleaved and/or modified from the prodrug the active drug is generated. Prodrugs are often useful because, in some situations, they are easier to administer than the parent drug. They are, for instance, bioavailable by oral administration whereas the parent is not. In certain instances, the prodrug also has improved solubility in pharmaceutical compositions over the parent drug. An example, without limitation, of a prodrug would be a compound as described herein which is administered as an ester (the “prodrug”) to facilitate transmittal across a cell membrane where water solubility is detrimental to mobility but which then is metabolically hydrolyzed to the carboxylic acid, the active entity, once inside the cell where water-solubility is beneficial. A further example of a prodrug might be a short peptide (polyamino acid) bonded to an acid group where the peptide is metabolized to reveal the active moiety. (See for example Bundgaard, "Design and Application of Prodrugs" in *A Textbook of Drug Design and Development*, Krosgaard-Larsen and Bundgaard, Ed., 1991, Chapter 5, 113-191).

[00112] In some embodiments, prodrugs are designed as reversible drug derivatives, for use as modifiers to enhance drug transport to site-specific tissues. The design of prodrugs to date has been to increase the effective water solubility of the therapeutic compound for targeting to regions where water is the principal solvent.

[00113] Additionally, prodrug derivatives of compounds described herein can be prepared by methods described herein are otherwise known in the art (for further details see Saulnier *et al.*, *Bioorganic and Medicinal Chemistry Letters*, 1994, 4, 1985). By way of example only, appropriate prodrugs can be prepared by reacting a non-derivatized compound with a suitable carbamylating agent, such as, but not limited to, 1,1-acyloxyalkylcarbanochloridate, *para*-nitrophenyl carbonate, or the like. Prodrug forms of the herein described compounds, wherein the prodrug is metabolized *in vivo* to produce a derivative as set forth herein are included within the scope of the claims. Indeed, some of the herein-described compounds are prodrugs for another derivative or active compound.

[00114] In some embodiments, prodrugs include compounds wherein an amino acid residue, or a polypeptide chain of two or more (e. g., two, three or four) amino acid residues is covalently joined through an amide or ester bond to a free amino, hydroxy or carboxylic acid group of compounds of the present invention. The amino acid residues include but are not limited to the 20 naturally occurring amino acids and also includes 4-hydroxyproline, hydroxylysine, demosine, isodemosine, 3-methylhistidine, norvaline, beta-alanine, gamma-aminobutyric acid, cirtulline, homocysteine, homoserine, ornithine and methionine sulfone. In other embodiments, prodrugs include compounds wherein a nucleic acid residue, or an oligonucleotide of two or more (e. g., two, three or four) nucleic acid residues is covalently joined to a compound of the present invention.

[00115] Pharmaceutically acceptable prodrugs of the compounds described herein also include, but are not limited to, esters, carbonates, thiocarbonates, N-acyl derivatives, N-acyloxyalkyl derivatives, quaternary derivatives of tertiary amines, N-Mannich bases, Schiff bases, amino acid conjugates, phosphate esters, metal salts and sulfonate esters. Compounds having free amino, amido, hydroxy or carboxylic groups can be converted into prodrugs. For instance, free carboxyl groups can be derivatized as amides or alkyl esters. In certain instances, all of these prodrug moieties incorporate groups including but not limited to ether, amine and carboxylic acid functionalities.

[00116] Hydroxy prodrugs include esters, such as though not limited to, acyloxyalkyl (e.g. acyloxymethyl, acyloxyethyl) esters, alkoxy carbonyloxyalkyl esters, alkyl esters, aryl esters, phosphate esters, sulfonate esters, sulfate esters and disulfide containing esters; ethers, amides, carbamates, hemisuccinates, dimethylaminoacetates and phosphoryloxymethyloxycarbonyls, as outlined in *Advanced Drug Delivery Reviews* 1996, 19, 115.

[00117] Amine derived prodrugs include, but are not limited to the following groups and combinations of groups:

as well as sulfonamides and phosphonamides.

[00118] In certain instances, sites on any aromatic ring portions are susceptible to various metabolic reactions, therefore incorporation of appropriate substituents on the aromatic ring structures, can reduce, minimize or eliminate this metabolic pathway.

#### Metabolites

[00119] In some embodiments, compounds of Formula I or Formula Ia are susceptible to various metabolic reactions. Therefore, in some embodiments, incorporation of appropriate substituents into the structure will reduce, minimize, or eliminate a metabolic pathway. In specific embodiments, the appropriate substituent to decrease or eliminate the susceptibility of an aromatic ring to metabolic reactions is, by way of example only, a halogen, or an alkyl group.

[00120] In additional or further embodiments, the compounds of Formula I or Formula Ia described herein are metabolized upon administration to an organism in need to produce a metabolite that is then used to produce a desired effect, including a desired therapeutic effect.

In some embodiments, dyestuffs or pigments are added to the tablets or dragee coatings for identification or to characterize different combinations of active compound doses.

[00129] Pharmaceutical preparations that are administered orally include push-fit capsules made of gelatin, as well as soft, sealed capsules made of gelatin and a plasticizer, such as glycerol or sorbitol. The push-fit capsules contain the active ingredients in admixture with filler such as lactose, binders such as starches, and/or lubricants such as talc or magnesium stearate and, optionally, stabilizers. In soft capsules, the active compounds are dissolved or suspended in suitable liquids, such as fatty oils, liquid paraffin, or liquid polyethylene glycols. In some embodiments, stabilizers are added.

[00130] In certain embodiments, delivery systems for pharmaceutical compounds may be employed, such as, for example, liposomes and emulsions. In certain embodiments, compositions provided herein can also include an mucoadhesive polymer, selected from among, for example, carboxymethylcellulose, carbomer (acrylic acid polymer), poly(methylmethacrylate), polyacrylamide, polycarbophil, acrylic acid/butyl acrylate copolymer, sodium alginate and dextran.

### **Combination Treatment**

[00131] The compounds according to Formula I or Formula Ia may be used in combination with one or more antibiotics in the treatment of bacterial infections. Such antibiotics may be

administered, by a route and in an amount commonly used therefore, contemporaneously or sequentially with a compound of Formula I or Ia. When a compound of Formula I or Ia is used contemporaneously with one or more antibiotic, a pharmaceutical composition in unit dosage form containing such other drugs and the compound of the present invention is preferred. However, the combination therapy may also include therapies in which the compound of Formula I or Ia and one or more antibiotic are administered on different overlapping schedules. It is also contemplated that when used in combination with one or more antibiotics, the antibiotics may be used in lower doses than when each is used singly.

**[00132]** Accordingly, the pharmaceutical compositions of the present invention also include those that contain one or more antibiotics, in addition to a compound according to Formula I or Formula Ia. In some embodiments, a pharmaceutical composition comprising a compound of Formula I or Ia further comprises a beta-lactam antibiotic. In certain embodiments, the beta-lactam antibiotic is a penicillin, cephalosporin, carbapenem, monobactam, bridged monobactam, or a combination thereof.

**[00133]** The above combinations include combinations of a compound of Formula I or Ia not only with one antibiotic, but also with two or more antibiotics. Likewise, compounds of formula I or Ia, either in combination with an antibiotic or by themselves, may be used in combination with other drugs that are used in the prevention, treatment, control, amelioration, or reduction of risk of bacterial infections or conditions associated with bacterial infections. Such other drugs may be administered, by a route and in an amount commonly used therefore, contemporaneously or sequentially with a compound of Formula I or Ia. When a compound of Formula I or Ia is used contemporaneously with one or more other drugs, a pharmaceutical composition containing such other drugs in addition to the compound of the present invention is preferred. Accordingly, the pharmaceutical compositions of the present invention also include those that also contain one or more other active ingredients, in addition to a compound of Formula I or Ia. The weight ratio of the compound of Formula I or Ia to the second active ingredient may be varied and will depend upon the effective dose of each ingredient. Generally, an effective dose of each will be used.

#### **Administration of Pharmaceutical Composition**

**[00135]** Suitable routes of administration include, but are not limited to, oral, intravenous, rectal, aerosol, parenteral, ophthalmic, pulmonary, transmucosal, transdermal, vaginal, otic, nasal, and topical administration. In addition, by way of example only, parenteral delivery includes intramuscular, subcutaneous, intravenous, intramedullary injections, as well as intrathecal, direct intraventricular, intraperitoneal, intralymphatic, and intranasal injections.

**[00136]** In some embodiments, compounds of Formula I or Formula Ia and compositions thereof are administered in any suitable manner. The manner of administration can be chosen based on, for example, whether local or systemic treatment is desired, and on the area to be treated. For example, the compositions can be administered orally, parenterally (e.g., intravenous, subcutaneous, intraperitoneal, or intramuscular injection), by inhalation, extracorporeally, topically (including transdermally, ophthalmically, vaginally, rectally, intranasally) or the like.

**[00137]** Parenteral administration of the composition, if used, is generally characterized by injection. Injectables can be prepared in conventional forms, either as liquid solutions or suspensions, solid forms suitable for solution or suspension in liquid prior to injection, or as

emulsions. A more recently revised approach for parenteral administration involves use of a slow release or sustained release system such that a constant dosage is maintained.

### **Assays for Antibacterial Activity**

[00138] Assays for the inhibition of beta-lactamase activity are well known in the art. For instance, the ability of a compound to inhibit beta-lactamase activity in a standard enzyme inhibition assay may be used (see, e.g., Page, *Biochem J*, 295:295-304 (1993)). Beta-lactamases for use in such assays may be purified from bacterial sources or preferably, are produced by recombinant DNA techniques, since genes and cDNA clones coding for many beta-lactamases are known (see, e.g., Cartwright & Waley, *Biochem J* 221 :505-12 (1984)).

[00139] Alternatively, the sensitivity of bacteria known, or engineered, to produce a beta-lactamase to an inhibitor may be determined. Other bacterial inhibition assays include agar disk diffusion and agar dilution (see, e.g., Traub & Leonhard, *Cancer Chemotherapy* 43 159-67 (1997)). Thus, a beta-lactamase may be inhibited by contacting the beta-lactamase enzyme with an effective amount of an inventive compound or by contacting bacteria that produce the beta-lactamase enzymes with an effective amount of such a compound so that the beta-lactamase in the bacteria is contacted with the inhibitor. The contacting may take place *in vitro* or *in vivo*. “Contacting” means that the beta-lactamase and the inhibitor are brought together so that the inhibitor can bind to the beta-lactamase. Amounts of a compound effective to inhibit a beta-lactamase may be determined empirically, and making such determinations is within the skill in the art. Inhibition includes both reduction and elimination of beta-lactamase activity.

### **Methods**

[00140] The present disclosure also provides methods for inhibiting bacterial growth, by, e.g., reducing bacterial resistance to a  $\beta$ -lactam antibiotic, such methods comprising contacting a bacterial cell culture, or a bacterially infected cell culture, tissue, or organism, with a beta-lactamase inhibitor described herein. Preferably, the bacteria to be inhibited by administration of a beta-lactamase inhibitor of Formula I or Ia are bacteria that are resistant to beta-lactam antibiotics. The term “resistant” is well-understood by those of ordinary skill in the art (see, e.g. Payne et al., *Antimicrobial Agents and Chemotherapy* 38 767-772 (1994), Hanaki et al., *Antimicrobial Agents and Chemotherapy* 30 1120-1126 (1995)).

[00141] These methods are useful for inhibiting bacterial growth in a variety of contexts. In certain embodiments, a compound of Formula I or Ia is administered to an experimental cell culture *in vitro* to prevent the growth of beta-lactam resistant bacteria. In certain other embodiments, a compound of Formula I or Ia is administered to a mammal, including a human to prevent the growth of beta-lactam resistant bacteria *in vivo*. The method according to this

embodiment comprises administering a therapeutically effective amount of a beta-lactamase inhibitor for a therapeutically effective period of time to a mammal, including a human.

Preferably, the beta-lactamase inhibitor is administered in the form of a pharmaceutical composition as described above. In some embodiments, a beta-lactam antibiotic is co-administered with the beta-lactamase inhibitor as described above.

### General Examples for the Preparation of Compounds of the Invention

[00146] The starting materials and intermediates for the compounds of this invention may be prepared by the application or adaptation of the methods described below, their obvious chemical equivalents, or, for example, as described in literature such as The Science of Synthesis, Volumes 1-8. Editors E. M. Carreira et al. Thieme publishers (2001-2008). Details of reagent and reaction options are also available by structure and reaction searches using commercial computer search engines such as Scifinder or Reaxys.

[00147] Certain compounds of the invention (I) (SCHEME 1) are prepared from the corresponding functional-group-protected boronic acid esters (II) by treatment with a Lewis acid such as BCl<sub>3</sub>, in a solvent such as dichloromethane, at a temperature between -78°C and 0°C followed by an aqueous quench.

SCHEME 1

[00148] Alternatively, (I) is obtained from (II) by treatment of (II) with aqueous hydrochloric acid (around 3-5 Molar) in dioxane at a temperature between room temperature and 100°C.

[00149] The requisite boronic acid esters (II) are obtained (SCHEME 2) by coupling of amine (III) with (carboxylic or sulphonic) acid (IV). This transformation is effected by first activating

the acid functionality as an acid chloride, anhydride or reactive ester (Va, Vb or Vc), followed by treatment of the activated substrate with (III) in a solvent such as DMF, DMA, NMP, THF or dichloromethane (or a mixture thereof) at about room temperature, usually in the presence of a non-nucleophilic base such as 4-methyl-morpholine, triethylamine or diisopropylethylamine.

SCHEME 2

**[00150]** Formation of the acid chloride (Va) involves treatment of (IV) with a chlorinating agent such as thionyl chloride, phosphorous pentachloride or oxalyl chloride, in a solvent such as dichloromethane, in the presence of a catalyst such as DMF, at around room temperature. In certain cases, DMF is also used as a co-solvent. Formation of the anhydride (Vb) (Z is C=O) involves treatment of (IV) with a sterically hindered acid chloride or chloroformate, such as trimethylacetyl chloride or isopropylchloroformate, in an inert solvent such as dichloromethane, in the presence of a non-nucleophilic base, such as triethyl amine or diisopropylamine at room temperature or below. Formation of the activated ester (Vc) involves treatment of (IV) with an activating reagent system such as EDCI, DCC/HOBt, HATU, BOP reagents or TBTU, in a solvent such as DMF, DMA, NMP or dichloromethane at room temperature or below

(*International Journal of Pharmaceutical Sciences Review and Research* (2011), **8**(1), 108-119).

**[00151]** The requisite acids (IV) are prepared by a number of different reaction sequences. While there are common themes and strategies among the illustrative examples cited below, the selection of an appropriate reaction sequence (including protecting group requirements) is dictated by the nature and arrangement of the functionality present in the target molecule and,

therefore, may involve obvious adaptations of the illustrated methods in order to be applied in a particular case.

[00152] In the case where  $Y_1$  is linked to CycA through an amine functionality, the requisite acids (IV) (SCHEME 3) are conveniently prepared from an appropriately substituted-carbocyclic ketone (VI). For example, treatment of (VI) with a suitable amine (VII) in the presence of a reducing agent such as sodium tri-acetoxyborohydride, sodium cyanoborohydride or sodium borohydride in a solvent such as dichloromethane, 1,2-dichloro-ethane, THF, methanol, acetic acid or a mixture thereof, at a temperature around room temperature gives ester (VIII). In the case where the use of a primary amine (VII,  $R^5 = H$ ) is called for, (VIII) can also be prepared by treatment of an equimolar mixture of (VI) and (VII,  $R^5 = H$ ) with a Lewis acid/dessicant, such as  $Ti(OEt)_4$ , in a solvent such as dichloromethane or 1,2-dichloroethane, at room temperature or above to provide the intermediate imine. This is followed by reduction of the imine with sodium borohydride, in a solvent such as methanol, at a temperature between -78°C and room temperature.

[00153] Acid (IV) is obtained from the ester (VIII) by formal hydrolysis of the ester functionality. The reaction conditions employed depend on the type of ester used. In the case of a methyl, ethyl or other simple alkyl, hydrolysis is usually achieved by brief treatment with an aqueous base, such as sodium hydroxide or lithium hydroxide, in a solvent mixture of THF, water and methanol. However, other acid protecting groups can also be used, such as benzyl, allyl, 2-trimethylsilyl-ethyl or 2,2,2-trichloroethyl. In these cases, conversion of the ester to the corresponding acid is achieved using the standard de-protection procedures in the literature (*Greene's Protective Groups in Organic Synthesis*. Fourth Edition. John Wiley & Sons, Inc. 2006).

[00154] In certain cases, it is convenient to perform the reductive amination sequence using a keto-acid derivative (VI,  $R = H$ ). In this case, treatment of an equimolar mixture of keto-acid (VI,  $R = H$ ) and amine (VII) with hydrogen gas in a solvent such as methanol, in the presence of a catalyst such as palladium on carbon provides acid (IV) directly.

SCHEME 3

[00155] In another approach to amino linked systems (SCHEME 4), treatment of ketone (VI) with a reducing agent, such as sodium borohydride in methanol at around 0°C or L-selectride in THF, at a temperature between -78°C and room temperature gives alcohol (IX). Treatment of the alcohol (IX) with methanesulphonyl chloride or *p*-toluene-sulphonyl chloride, in the presence of a non nucleophilic base, such as triethylamine or DIEA, in a solvent such as dichloromethane or pyridine, at around 0°C provides the corresponding sulphonate ester (X). Displacement of the sulphonate group with azide by treatment of (X) with sodium azide or a tetra-alkylammonium azide in a solvent such as DMA, DMF, NMP, acetonitrile or DMSO, at a temperature between room temperature and 120°C, yields the azide (XI). Reduction of the azide with triphenylphosphine and water in THF at around room temperature (Staudinger reaction) yields the primary amine (XII). Further derivatization of (XII), where appropriate, can be accomplished by reductive amination with an appropriate aldehyde or ketone, using conditions already described to give (XV).

SCHEME 4

[00156] Alternatively, formation of the *N*-BOC derivative of (XII) by treatment with BOC<sub>2</sub>O, in the presence of a non nucleophilic base such as triethylamine or DIEA, in a solvent such as dichloromethane, at around room temperature gives carbamate (XIII). Treatment of (XIII) with an alkyl halide or sulphonate in the presence of a base, such as sodium hydride, potassium carbonate or tetramethylguanidine, in a solvent such as DMF, DMA, NMP, THF, DMPU or ethanol (or a mixture thereof), at room temperature or below, provides (XIV). Cleavage of the BOC group with an acid, such as TFA in dichloromethane or HCl in dioxane, ethyl acetate or

ether, at around room temperature, provides the secondary amine (XV). Further derivatization of (XV), where appropriate, can be accomplished by reductive amination with an appropriate aldehyde or ketone, using conditions already described to give (VIII). Hydrolysis of (VIII) as already outlined yields (IV).

[00157] In the case where  $Y_{P-1}$  is a guanidine, the guanidino group is derived from the appropriate carbocyclic primary (XII) or secondary amine (XV) (SCHEME 5) by treatment with a reagent such as 1,3-Di-tert-butyloxycarbonyl-S-methylisothiourea, in a solvent such as DMF, (*Synthesis*, (2004), 37-42) or pyridine at room temperature or above, or by treatment with *N,N'* Bis-(BOC)-1H-pyrazole-1-carboxamidine in the presence of a base such as diisopropylethylamine, in a solvent such as DMF or DMA at around room temperature. Selective cleavage of the ester functionality, as already described, provides the corresponding acid (IV).

SCHEME 5

[00158] Alternatively, the guanidinyl group can be introduced by treatment of an appropriate carbocyclic alcohol (IX) with a reagent such as Cbz-guanidine, in the presence of triphenylphosphine and diethyl-azo-dicarboxylate, in a solvent such as THF (Mitsunobu conditions: *Chemical Reviews*, (2009), 109, 2551-2651) to give (VIII) directly.

[00159] In the case where  $Y_1$  is an amidine linked to Cyc A through nitrogen, the requisite acids (SCHEME 6) are prepared from the appropriate primary (XII) or secondary amine (XV) by treatment with a suitable alkyl thioimidate, such as the 2-naphthylmethylthioimidate derivative (XVI), in a solvent such as ethanol at a temperature between 0°C and room temperature (*Tetrahedron Letters*, (1997), **38**(2), 179-182) to give (XVII). Protection of the amidine (XVII) as a carbamate derivative, such as BOC or Cbz under standard conditions, followed by selective ester hydrolysis provides acid (IV).

SCHEME 6

[00160] In the case where  $Y_1$  is an amidine linked to Cyc A through carbon, the amidine functionality (SCHEME 7) is introduced by conversion of an appropriate carbocyclic ketone (XVIII) to the corresponding exocyclic nitrile (XIX) by treatment (XVIII) with toluenesulphonyl-methylisocyanide (*Journal of Organic Chemistry* (1977), **42**(19), 3114-18) in the presence of a base such as  $\text{KOBu}^t$  in a solvent such as DMSO or DME containing about 2% of *t*-butanol or ethanol at a temperature between 0°C and 50°C. Treatment of (XIX) with  $\text{HCl}$  in methanol to form the corresponding imidate ester (XX) is followed by reaction of this intermediate with an appropriate amine ( $\text{R}^4\text{R}^5\text{NH}$ ), in a solvent such as methanol or THF at around room temperature to give the amidine (XXI). In certain cases, it is convenient to effect direct amidine formation from the nitrile (XIX) using a suitable methyl-chloroaluminum amide, in a solvent such as toluene at around 80°C (*Tetrahedron Letters*, (1990), **31**(14), 1969-1972). Furthermore, in the case where  $\text{R}^5 = \text{H}$ , the amidine functionality can also be introduced by

treatment of the appropriate carbocyclic nitrile (XIX) with hydroxylamine or an *O*-alkyl-hydroxylamine to give the N-hydroxyl-( or alkoxy)-amidine (XXII,  $R^5 = OH, OR$ ). This is followed by removal of the protecting groups by catalytic hydrogenolysis to provide the amidine (XXIII). Selective acylation of the amidine functionality in (XXIII) by treatment with BOC anhydride or Cbz chloride, as previously described yields primary alcohol (XXIV). Conversion of the primary-alcohol (XXIV) to the corresponding acid (IV) is accomplished using one of a number of oxidation protocols such as  $NaIO_4$  with catalytic  $RuCl_3$  in a solvent mixture of water/CCl<sub>4</sub>/CH<sub>3</sub>CN in the ratio 3/2/2, at around room temperature (*Journal of Organic Chemistry*, (1981), **46**(19), 3936-8) or with pyridinium dichromate in DMF (*Tetrahedron Letters*, (1979), **20** (52), 399).

SCHEME 7

[00161] In certain cases, the primary alcohol (XXIV) is oxidized to the corresponding carboxylic acid using a two-step procedure, involving initial oxidation to the aldehyde using a DMSO based oxidant system, such as Swern oxidation (*Organic Reactions*. (1990), **39**, 297–572.) or by treatment with excess Dess Martin periodinane in a solvent such as dichloromethane at around room temperature. Subsequent oxidation of the aldehyde is accomplished by treatment with sodium chlorite / sodium dihydrogenphosphate in the presence of tetramethylethylene, in a solvent such as *t*-butanol / water at around room temperature (*Journal of Organic Chemistry*, (1980), **45**, 4825).

[00162] In the case where  $Y_1$  is a nitrogen substituted methylene group, the requisite acids (SCHEME 8) are prepared from the appropriate carbocyclic- ketones (XVIII) by conversion of the ketone functionality into, first, the corresponding hydroxyl-methyl derivative by treatment with an olefination reagent such as methyltriphenylphosphonium bromide in the presence of sodium hexamethyldisilazide, in a solvent such as THF at around 0°C. (Wittig reaction) or by treatment with lithium trimethylsilylmethane/CeCl<sub>3</sub> at around 0°C to room temperature, in a solvent such as THF or ether (Peterson reaction) (*Journal of Organic Chemistry*, (1987) 52(2), 281-3) or by reaction with the Petasis modified Tebbe reagent (dicyclopentadienyl-dimethyltitanium) in THF/toluene at around 60°C (*Journal of the American Chemical Society*, (1990), **112** (17) 6392–6394 to give (XXV). This is followed by hydroboration oxidation of the exocyclic alkene in (XXV) with a reagent such as borane THF or an alkyl derivative, at around 0°C, in a solvent such as THF, followed by oxidative workup with hydrogen peroxide NaOH aq. to provide (XXVI). Conversion of the hydroxymethyl (XXVI) into the functionalized amino-methyl derivative (XXVII) is accomplished by conversion to the corresponding tosylate, azide and primary amine as described above. Alternatively, oxidation of (XXVI) to the aldehyde (XXVIII) followed by reductive amination of (XXVIII) with an amine ( $R^4R^5NH$ ), as already described, also provides amine (XXVII). Conversion of (XXVII) to the requisite acid (IV) is accomplished by side chain modification as previously described.

SCHEME 8

[00163] In an alternative approach to systems wherein  $Y_1$  is a nitrogen substituted methylene group, CycA is a 5- 7 membered carbocycle and Z is a carbonyl group, the requisite carboxylic acids (IV) are prepared from an acrylamide derivative (XXIX) (SCHEME 9). (XXIX) is condensed, in a Diels Alder reaction, with an appropriately substituted diene, such as siloxy-diene (XXX), in an inert solvent such as toluene, xylene or DMA at a temperature between 70° and 190 °C to give the carbocyclic-silyl-enol-ether (XXXI).

SCHEME 9

[00164] Carbocyclic-silyl-enol-ether (XXXI) is then elaborated to provide several of the requisite carboxylic acids (IV) by the application of known functional group transformations. For example (SCHEME 10), treatment of (XXXI) with *N*-phenyl-triflimide and CsF in a sealed system, using a solvent such as DME, at around room temperature or below, furnishes the corresponding enol triflate (XXXII) (*Journal of the American Chemical Society*, (2002) **124**, 11290-11291). Methoxy-carbonylation of (XXXII) with carbon monoxide/ methanol in the presence of a non nucleophilic base, such as triethylamine and a catalyst, such as  $\text{Pd}(\text{OAc})_2$ , in conjunction with 1,3-(bis-diphenylphosphino)-propane, in a solvent such as DMSO, at a temperature between 50 and 100°C provides unsaturated ester (XXXIII). Unsaturated ester (XXXIII) is reduced using a heterogeneous Pd, Rh or Pt catalyst, such as 10% Pd on carbon, under an atmosphere of hydrogen gas (1-4 atm), in a solvent such as ethyl acetate, methanol or THF ( or a mixture thereof) at room temperature to 70 °C to give the saturated ester (XXXIV). Alternatively, in certain cases, unsaturated-ester (XXXIII) may be reduced by treatment with excess Magnesium, in a solvent such as methanol, at around room temperature (*Tetrahedron Letters*, (1986); **27**(21), 2409-2410) to provide (XXXIV).

SCHEME 10

[00165] In suitable cases, selective reduction of the amide functionality of intermediate (XXXIV) to provide the corresponding amine (XXXV) (SCHEME 11) is accomplished by treatment of (XXXIV) with a silane reducing agent, such as diphenylsilane and a rhodium catalyst such as rhodiumhydrocarbonyltriphenylphosphine, in a solvent such as THF, at around room temperature (*Tetrahedron Letters*, (1998); **39**(9), 1017) or by treatment with 1,1,3,3-tetramethyldisiloxane and a catalytic amount of chloroplatinic acid hydrate, in a solvent such as toluene, at a temperature between room temperature and 90 °C (*Journal of the American Chemical Society*, (2009); **131**(41), 15032-15040).

SCHEME 11

[00166] The ester functionality in (XXXV) is hydrolyzed to give the requisite acid (IV) by brief treatment with a base such as sodium hydroxide or lithium hydroxide, in a solvent such as THF/methanol/water, at around room temperature.

[00167] Alternatively, Reduction of the amide functionality in (XXXIV), with concomitant reduction of the ester group, to give (XXXVI) is accomplished by treatment of (XXXIV) with a hydride reducing agent, such as lithium aluminum hydride, in an ethereal solvent such as THF, diethyl-ether, dimethoxy-ethane or methyl-*t*-butyl-ether, at a temperature between 0°C and 65 °C. Conversion of the resulting amino-alcohol (XXXVI;  $\text{R}^4, \text{R}^5 = \text{H}$ ) to the corresponding acid (IV) is accomplished by amine derivitization and oxidation of the primary alcohol as already described.

[00168] The corresponding one carbon homologated carboxylic acid (IV) where Cyc A is a six membered ring,  $\text{L}, \text{M} = \text{bond}$ ,  $\text{m} = 0$ ,  $\text{n} = 1$ ,  $\text{Y}_1 = (\text{R}^4\text{R}^5\text{NCH}_2)$  (SCHEME 12) is also prepared from carbocyclic silyl enol ether (XXXI). Treatment of (XXXI) with potassium carbonate in methanol at around room temperature or with tetra-*n*-butylammonium fluoride hydrate in a solvent such as THF (and where appropriate, buffered with an equimolar amount of acetic acid) provides ketone (XXXVII). Treatment of (XXXVII) with a trialkyl-phosphonoacetate, such as triethylphosphonoacetate, in a solvent such as THF, in the presence of a base such sodium

hydride, at a temperature between about -5 °C and room temperature gives the corresponding  $\alpha,\beta$ -unsaturated ester (XXXVIII) (*Liebigs Annalen/Recueil*, (1997), 7, 1283-1301.). Reduction of the alkene and amide functionality in (XXXVIII) and subsequent processing (ester hydrolysis or alcohol oxidation), analogous to that described above furnishes the requisite acid (IV).

SCHEME 12

[00169] The carboxylic acid (IV) where Cyc A is a six membered ring, L,M = bond, m = 0, n = 2,  $\text{Y}_1 = (\text{R}^4\text{R}^5\text{NCH}_2)$  (SCHEME 13) is prepared from alcohol (XXXVI) by oxidation to the corresponding aldehyde (XXXIX) under standard conditions followed by a Horner-Wadsworth-Emmons reaction, as described above, to provide  $\alpha,\beta$ -unsaturated ester (XL). Reduction of the alkene in (XL) and ester hydrolysis analogous to that described above furnishes the requisite acid (IV).

[00170] The carboxylic acid (IV) where Cyc A is a six membered ring, L = O, M = bond, m = 0, n = 1,  $\text{Y}_1 = \text{R}^4\text{R}^5\text{NCH}_2$  (SCHEME 14) is prepared from ketone (XXXVII) by treatment with a reagent such as sodium borohydride in methanol at around 0°C or L-selectride in THF, at a temperature between -78°C and room temperature to give alcohol (XLI). Condensation of (XLI) with ethyl diazoacetate in the presence of a catalyst such as Rh(acac) dimer in a solvent such as dichloromethane provides the alkoxyacetate derivative (XLII). Selective amide reduction and ester hydrolysis of (XLII) as already described yields (IV).

SCHEME 13

SCHEME 14

[00171] The carboxylic acid (IV) where Cyc A is a six membered ring, L =  $NR_4$ , M = bond, m = 0,  $Y_1 = (R^4R^5NCH_2)$  (SCHEME 15) is prepared from ketone (XXXVII) by treatment with an

appropriate amino ester (XLIII) under the reductive amination conditions already described to yield (XLIV). Selective amide reduction and ester hydrolysis of (XLIV), as already described, provides the requisite acid (IV).

[00172] The seven membered carbocyclic systems (IV) (SCHEME 16) are accessed by ring expansion of carbocyclic-silyl-enol ether (XXXI).

[00173] For example, treatment of (XXXI) with a carbene-synthetic-equivalent, such as Simmons Smith reagent, followed by mild oxidation of the resulting cyclopropane, using a reagent such as  $\text{FeCl}_3$  (*Journal of Organic Chemistry*, (1985), **50**(4), 531-534) or CAN /  $\text{NaOAc}$  (*Organic Letters*, (2007), **9**(7), 1323-1326) provides the seven membered enone (XLV).

Treatment of (XLV) with a silane, such as PhMe<sub>2</sub>SiH, in the presence of a catalyst, such as Wilkinson's catalyst (Ph<sub>3</sub>P)<sub>3</sub>RhCl, either neat or in a solvent such as benzene or toluene, provides the ring expanded silyl-enol ether (XLVI). This seven membered carbocycle is processed in a manner directly analogous to its six membered ring congener (XXXI) described above, to furnish the requisite acids (IV, CycA = heptane).

### SCHEME 15

SCHEME 16

[00174] In certain cases, it is convenient to prepare the carbocyclic systems (IV, CycA = cyclopentane) (SCHEME 17) from ketone (XXXI) by Favorskii rearrangement of the corresponding  $\alpha$ -halo-ketone (XLVII) (*Current Organic Chemistry* (2005), 9(17), 1713-1735). For example, treatment of (XXXI) with a halogenating reagent, such as bromine, NCS, or pyridinium tribromide in an inert solvent such as dichloromethane or hexane, at a temperature between -78 °C and room temperature furnishes the  $\alpha$ -halo-ketone (XLVII). Application of the Favorskii rearrangement conditions to (XLVII) (slow addition to a suspension of sodium methoxide in ether, at around room temperature) then provides the ring contracted ester-substituted-carbocycle (XLVIII).

SCHEME 17

[00175] This intermediate is processed in a manner directly analogous to its six membered ring congener (XXXIV) described above, to furnish the requisite acids (IV).

[00176] In certain cases the carbocyclic systems (IV, CycA = cyclopentane) are prepared by a cycloaddition reaction between an acrylamide derivative (XXIX) and 2-((trimethylsilyl)methyl)allyl acetate (XLIX), in a solvent such as THF, toluene or xylene, in the presence of a catalyst such as bis (diphenylphosphinopropane) / palladium acetate, at a temperature between 70° and 160 °C (*Journal of the American Chemical Society*. (1979), 101(21), 6429-6431) to give (L). The exocyclic olefin in (L) is oxidatively cleaved by treatment with catalytic amounts of osmium tetroxide (*Org. Synth. Oxid. Met. Compd.* (1986), 633-93. Publisher: Plenum, New York) in the presence of a co-oxidant such as *N*-methyl morpholine *N*-oxide, in a solvent such as *tert*-butanol / water to yield the corresponding di-hydroxy-derivative (LI). This diol is then oxidatively cleaved using sodium periodate, in a solvent such as THF/water, at around room temperature, to give (LII).

SCHEME 18

[00177] Carbocyclic ketone (LII) is then processed in a manner directly analogous to its six membered ring congener (XXXVII) to provide the corresponding acids (IV).

[00178] In the case where Y<sub>1</sub> and Y<sub>2</sub> are both nitrogen substituted methylene groups such that Y<sub>1</sub> and Y<sub>2</sub> are positioned vicinally on the carbocycle, the requisite acids (IV) are prepared as illustrated above (SCHEMES 9-18) except starting with a fumaric or maleic acid diamide in place of an acrylamide.

[00179] In the case where CycA is a 5, 6, or 7 membered carbocycle wherein Y<sub>3</sub> and Y<sub>4</sub> taken together form a ring, the requisite carboxylic acids (IV) (SCHEME 19) are prepared by the methods described above, except a cyclic siloxy-diene such as (LIII) is employed in the Diels Alder reaction to provide the bicyclic silyl-enol ether (LIV). The starting diene structures are prepared from the corresponding  $\alpha,\beta$ -unsaturated ketone (LV) by treatment of the appropriate enone with trialkylsilyl triflate in the presence of a base such as triethylamine, proton sponge or DBU in a solvent such as ether at 0°C or above.

SCHEME 19

[00180] In the case where CycA is a 5, 6 or 7 membered carbocycle, M = bond, O, NR<sup>4</sup>, Y<sub>1</sub> and Y<sub>2</sub> are each linked to CycA through a nitrogen atom and Y<sub>1</sub> and Y<sub>2</sub> are positioned vicinally to each other on the carbocycle, the requisite acids (IV) (SCHEME 20) are prepared from the appropriate cyclic olefins (LVI). For example, treatment of (LVI) with sodium azide, in the presence of a mild oxidant, such as Mn(OAc)<sub>3</sub>(H<sub>2</sub>O)<sub>2</sub> and an acid such as acetic acid or trifluoroacetic acid, in a solvent such as acetonitrile, at a temperature between -30°C and 0°C provides the diazide (LVII) in predominantly the trans isomer configuration (*Synthetic Communications*, **28**(10), 1913-1922; 1998). Subsequent reduction of the bis-azide by treatment with a reducing agent, such as triphenylphosphine, in a solvent such as THF, followed by *in situ* hydrolysis of the intermediate aza-phosphorane by the addition of excess water yields the bis-amine (LVIII). In certain instances, reduction of the bis azide is also achieved by treatment with hydrogen gas in the presence of a catalyst such as palladium on carbon in a solvent such as THF or methanol.

[00181] This bis-primary-amine (LVIII) is protected as a BOC, Cbz or other suitable *N*-protected derivative (Greene's Protective Groups in Organic Synthesis; 4th Edition: John Wiley & Sons, Inc., 2006). For example, treatment of (LVIII) with an appropriate anhydride or chloroformate, in the presence of a base such as triethylamine, in a solvent such as THF or dichloromethane, at around room temperature provides the carbamate intermediate (LIX). Where appropriate, the carbamate is further derivatized by treatment with a suitable alkylating agent, in the presence of a base, such as K<sub>2</sub>CO<sub>3</sub>, in a solvent such as DMF, DMA, or acetonitrile to give (LX). Removal of the carbamate protecting group, followed by treatment of the resulting secondary amine with an aldehyde or ketone in the presence of a reducing agent such as sodium borohydride, sodium cyanoborohydride or sodium triacetoxyborohydride in a solvent such as

dichloromethane, 1,2-dichloroethane, methanol or THF at around room temperature provides (LXI). Ester hydrolysis of (LXI), as described above, yields the desired acid (IV).

SCHEME 20

[00182] Alternatively, treatment of the appropriate cyclic olefin (LVI) (SCHEME 21) with an oxidant such as meta-chloroperbenzoic acid in a solvent such as dichloromethane at around 0°C provides the corresponding cyclic epoxide (LXII). Ring opening of the epoxide by treatment with sodium azide and ammonium chloride in a solvent such as ethanol, poly-ethylene-glycol, or DMF / water at a temperature between room temperature and 80°C, provides the trans hydroxyl azide (LXIII). Reaction of (LXIII) with methanesulphonyl chloride in pyridine at around 0°C yields the mesylate (LXIV). Treatment of (LXIV) with tetrabutylammonium azide in a solvent such as toluene provides the cis-oriented bis azide (LXV). Processing of intermediate (LXV) is carried out as previously described to provide acids (IV).

SCHEME 21

[00183] Where appropriate, the cyclic olefins (LVI) (SCHEME 22) are prepared from acyclic starting materials by olefin metathesis. For example, treatment of ester (LXVI) with a strong base, such as LDA in a solvent such as THF, THF/DMPU or DME at a temperature between -78°C and 0°C forms the corresponding lithium enolate. This lithium enolate is treated with a suitable halo-alkyl olefin to yield the bis-olefin (LXVII). Treatment of (LXVII) with one of a range of Grubb's or Schrock metathesis catalysts (*Tetrahedron*, (2012), **68**(2) 397-421; *Organic Letters*, (2007), **9**(23), 4885-4888; *Tetrahedron*, (2004), **60**, 7117-7139) in a solvent such as dichloromethane, at room temperature or above or, in an aqueous PEG<sub>500</sub> dimethyl ether solution, provides the cyclic olefin (LVI, M = bond, n = 0).

[00184] It should be noted that the cyclic silyl-enol ethers or alkyl enol ethers corresponding to (LVI) which are precursors of cyclic ketones are also conveniently prepared by this approach by employing a suitable acyclic silyl or alkyl enol ether in the ring closure metathesis reaction (*Tetrahedron Letters*, (2001), **42** (45), 8023).

[00185] Subsequent standard functional group transformations on the exocyclic alkoxy carbonyl group of (LVI,  $\text{M} = \text{bond}, n = 0$ ) provides a range of homologous alkoxy carbonyl-alkyl substituted cyclic olefins (SCHEME 23). For example, reduction of the ester functionality by treatment with a reducing agent such as DIBALH, in a solvent such as toluene, THF or

WO 2014/089365

PCT/US2013/073428

dichloromethane at a temperature between -78° and 0°C provides the primary alcohol (LXVIII). Oxidation of (LXVIII) with one of a range of oxidants described above, (such as Dess-Martin periodinane), in a solvent such as dichloromethane yields the corresponding aldehyde (LXIX). Wittig olefination of (LXIX) using a triphenylphosphoranylidine-acetate ester (LXX), in a solvent such as toluene or THF, at a temperature between room temperature and 80°C provides the unsaturated ester (LXXI). Selective reduction of the conjugated double bond in (LXXI) to the corresponding saturated ester (LVI, n = 2) is accomplished by treatment with magnesium ribbon, in a solvent such as methanol, at around room temperature.

[00186] Alternatively, treatment of alcohol (LXVIII) with *p*-toluenesulphonyl chloride, in a solvent such as pyridine or dichloromethane, in the presence of a base such as triethylamine or DMAP, at a temperature between -20°C and room temperature provides the tosylate derivative (LXXII). Displacement of the tosyl group in (LXXII) by treatment with sodium cyanide in DMF, DMA or DMSO, at a temperature between room temperature and 160°C provides the nitrile (LXXIII). Solvolysis of this nitrile by treatment with HCl in an appropriate alcohol (such as methanol or ethanol) yields (LVI, M = bond, n = 1).

[00187] Ring closure metathesis can be used to provide access to (LVI, M = O or NR<sub>4</sub>) by use of the appropriate alkoxy or amino substituted bis alkene substrate (SCHEME 24). For example, coupling of an appropriately substituted aldehyde or imine (LXXIV) with a suitable Grignard provides the secondary alcohol (sulphinamine) (LXXV). Alkylation or reductive amination of (LXXV) under standard conditions provides (LXXVI). Exposure of (LXXVI) to ring closure metathesis conditions, as described above provides the carbocyclic alkene (LVI, M = O, NR<sub>4</sub>).

SCHEME 24

[00188] In the case where CycA is a 4-7 membered carbocycle, Y<sub>1</sub> is a 1-amino-t-amino-alkyl group (t = 2, 3, 4) the requisite acids (IV) (SCHEME 25) are generally prepared by sequential installation of the amino functionality into the corresponding hydroxyl-substituted or carboxy-substituted carbon scaffold. For example, Selective reduction of the ester functionality in (LXXVIII) to the corresponding alcohol (LXXIX) is accomplished by treatment with a reducing agent, such as borane:THF, in a solvent such as THF, at around room temperature. Oxidation of the primary alcohol to the corresponding aldehyde (LXXX) is achieved by one of a wide range of standard oxidation protocols such as Swern oxidation or Dess-Martin periodane oxidation. The aldehyde is then treated with an olefin substituted-alkyl Grignard reagent, in a solvent such as THF, diethyl ether or DME at a temperature between about -50°C and room temperature to give secondary alcohol (LXXXI). In certain cases, where the requisite olefin substituted-alkyl is an allyl (t = 1), condensation with the aldehyde (LXXX) can also be effected using an allyl boronate or allyl silane in the presence of a Lewis acid such as TiCl<sub>4</sub> or BF<sub>3</sub> etherate in a solvent such as dichloromethane at a temperature between -78 °C and room temperature. The olefin substituted secondary alcohol (LXXXI) is then converted to the corresponding amine by treatment with *p*-toluenesulphonylchloride in the presence of a base such as triethylamine or DMAP, in a solvent such as dichloromethane or pyridine, at a temperature between -20°C and room temperature to afford the corresponding tosylate (LXXXII). The tosylate is then treated with azide salt such as sodium azide, tetrabutylammonium azide in a solvent such as DMF, DMA or DMSO at a temperature between room temperature and 160°C to yield the corresponding azide (LXXXIII). This intermediate is reduced to the primary amine (LXXXIV) and subsequently derivatized as described above to give (LXXXV). Alternatively, Introduction of the primary amino functionality is effected by conversion of the secondary alcohol (LXXXI) to the corresponding phthalimide (LXXXVI) under Mitsunobu conditions (*Chemical Reviews*, (2009) 2551-2651) followed by deprotection of the phthalimide by treatment with excess hydrazine in a solvent such as ethanol at room temperature or above to provide the primary amine (LXXXIV).

[00189] Installation of a second amino functionality into (LXXXV) is accomplished by oxidative cleavage of the olefin as previously described, to furnish aldehyde (LXXXVII). This intermediate is converted to the requisite amine (LXXXVIII) by direct reductive alkylation or by reduction to the primary alcohol using a reducing agent such as sodium borohydride in a solvent such as THF/methanol at a temperature between -78°C and 0°C, followed by derivatization of the resulting primary alcohol (via the corresponding tosylate, azide and primary amine) as described above. Side chain processing of (LXXXVIII) as previously described gives (IV).

SCHEME 25

[00190] In the particular case where  $Y_1$  is an optionally substituted 1-amino-2-amino-ethyl group installation of the diamine functionality can be accomplished by direct amination of the appropriate exocyclic alkene ( $Mn(OAc)_3/NaN_3/TFA$  then reduction). The requisite exocyclic olefin is prepared by Wittig, Peterson or Tebbe type olefination of (LXXX) as already described.

[00191] In the case where CycA is an optionally substituted 4-7 membered carbocycle,  $Y_1$  is an optionally substituted t-amino-alkyl group ( $t=1, 2, 3, 4$ ),  $Y_2$  is an optionally substituted amine, and  $Y_1$  and  $Y_2$  are both attached to the same ring carbon of CycA, the requisite acids (IV) (SCHEME 26) are prepared from the appropriate carbocyclic ketone precursor (LXXXIX) by treatment with *t*-butylsulphinamine (*Chemical Reviews*, (2010), **110**(6), 3600-3740), typically in a solvent such as THF or methanol, in the presence of  $Ti(OEt)_4$ , at a temperature between room temperature and  $60^\circ C$ . The resulting *t*-butylsulphinimine is then condensed with an appropriate

organometallic, such as an olefin substituted alkyl Grignard (or where appropriate, a  $\text{CeCl}_3$  modified Grignard reagent) in a solvent such as THF, ether, dichloromethane or toluene at a temperature between  $-60^\circ$  and  $0^\circ\text{C}$  to provide the sulfinamine substituted carbocycle (XC).

Removal of the sulfinyl group is effected by treatment with an acid such as trifluoroacetic acid in a solvent such as dichloromethane at around room temperature to yield the corresponding primary amine (XCI,  $\text{R}^4, \text{R}^5 = \text{H}$ ). The primary amine is derivitized or protected, as appropriate, by methods described above. Processing of the alkene functionality to provide the appropriate amine is effected by oxidative cleavage ( $\text{OsO}_4 / \text{NMO}$  then  $\text{NaIO}_4$ ) then reductive amination of the resulting aldehyde to give (XCII). Alternatively, hydride reduction of the aldehyde and derivitization of the alcohol, as described above, also provides (XCII). Conversion of (XCI) to the requisite acid is accomplished by processing of the acid side chain precursor group Y as already described.

SCHEME 26

[00192] In the specific case where  $t = 1$ , (IV) is prepared from ketone (LXXXIX) by a Strecker reaction (*Synthesis*, (2007), 1230-1234. *Organic Letters*, (2008), **10**, 1509-1512) followed by

reduction of the resulting nitrile group. Subsequent processing of this intermediate to provide (IV) is carried out as already described.

**[00193]** In a variation of the above system wherein CycA is an optionally substituted 4-7 membered carbocycle, Y<sub>1</sub> is an t-amino-alkyl group (t = 2, 3, 4), Y<sub>2</sub> is an amine, Y<sub>1</sub> and Y<sub>2</sub> are both attached to the same ring carbon of CycA and Y<sub>1</sub> and Y<sub>2</sub> are connected to each other through their substituents (by a CH<sub>2</sub> group), the requisite acids (IV) (SCHEME 27) are prepared from the intermediate (XCI) by treatment with OsO<sub>4</sub> in a solvent such as acetone/water in the presence of an oxidant such as *N*-methyl-morpholine *N*-oxide to yield the corresponding diol. This intermediate is treated with sodium periodate in THF/water to form the truncated aldehyde (XCIII). (XCIII) is then condensed with an  $\alpha$ -phosphonoglycine ester derivative, such as the BOC-protected  $\alpha$ -phosphono-glycine trimethyl ester, in the presence of a base such as potassium *t*-butoxide in a solvent such as dichloromethane at a temperature between -78°C and -50°C to give the unsaturated ester (XCIV) (*Tetrahedron*, (2001), **57**, 6463). (XCIV) is selectively hydrogenated using a cationic rhodium phosphine-phosphite catalyst to give the corresponding saturated-BOC-TCEOC-protected amino ester. This intermediate is de-protected under standard conditions (Zinc /acetic acid in THF) to yield the BOC protected amino ester (XCV).

**[00194]** Cyclization of the amino ester, in the presence of a base such as DBU, in a solvent such as toluene, at a temperature between room temperature and 110 °C provides lactam (XCVI). Selective reduction of the tertiary amide in (XCVI) using a silane reducing agent in the presence of rhodiumhydrocarbonyltriphenylphosphine, or chloroplatinic acid, as described above, followed by amine derivatization provides (XCVII). Subsequent processing of the side chain Y, as previously described, provides the requisite acids (IV).

SCHEME 27

[00195] In the case where CycA is an optionally substituted 4-7 membered carbocycle,  $Y_1$  is an optionally substituted t-amino-alkyl group ( $t = 2, 3, 4$ ),  $Y_2$  is an optionally substituted amine, and the ring carbon of CycA attached to  $Y_1$  and the ring carbon of CycA attached to  $Y_2$  are positioned vicinal to each other, the requisite acids (IV) (SCHEME 28) can be prepared from the appropriate cyclic ketone (XCVIII). For example, in the case where  $t = 2$ , treatment of (XCVIII) with a trialkylsilyl triflate in the presence of a base such as triethylamine in a solvent such as ether furnishes the corresponding silyl enol ether (XCIX). Reaction of this intermediate with a nitro-olefin ( $R^6R^7C=CR^6NO_2$ ) in the presence of a Lewis acid such as  $TiCl_4/(TiOiPr)_4$  or  $SnCl_4$  in a solvent such as dichloromethane at a temperature between  $-78^\circ C$  and room temperature provides the nitro-alkyl substituted cyclic ketone (C) (*Journal of the American Chemical Society*, **106**(7), 2149-56; 1984; *Helvetica Chimica Acta*, **82**(11), 1829-1842; 1999; *Canadian*

*Journal of Chemistry*, **65**(4), 836-50; 1987). Hydride reduction of this intermediate using a reagent such as lithium aluminum hydride in a solvent such as THF at a temperature between -20°C and reflux provides amino alcohol (CI). The amino group of (CI) is selectively derivitized as described above to give (CII). Installation of the second amino group is effected by derivitization of the carbocyclic alcohol (CII) using methods described above to provide (CIII). Removal of the benzyl ether protecting group and oxidation of the resulting primary alcohol is effected as described previously to yield the requisite carboxylic acid (IV).

SCHEME 28

[00196] For the case where  $t = 1$  (SCHEME 29), installation of the appropriate side chain functionality is achieved by reaction of silyl-enol ether (XCIX) with an iminium salt (where appropriate generated in situ from the *N*,*O*-acetal and trimethylsilyltriflate) in a solvent such as

dichloromethane at a temperature between -78°C and room temperature to provide amino ketone (CIV). Processing of the ketone in (CIV), as previously described, provides the diamino-functionalized scaffold (CV). Thereafter, removal of the benzyl ether and oxidation of the resulting primary alcohol in the usual manner yields the desired acid (IV).

SCHEME 29

[00197] For the case where  $t = 3$  (SCHEME 30), installation of the appropriate side chain functionality is achieved by reaction of silyl-enol ether (XCIX) with methyl lithium, in a solvent such as THF, at a temperature between -20°C and 0°C to generate the corresponding Lithium enolate regioselectively. This is followed by treatment of the enolate with an electrophile such as an acrylamide (or acrylonitrile) to give (CIV). Processing of the ketone as already described provides the amine functionalized amide (CVII). Reduction of the amide with a reducing agent such as Lithium aluminum hydride in a solvent such as THF at a temperature between -10°C and reflux yields the diamine (CVIII). This intermediate is then processed, as described above (debenzylation then oxidation), to provide the requisite acid (IV).

SCHEME 30

**[00198]** In the case where A is an optionally substituted 4-7 membered carbocycle,  $\text{Y}_1$  is an optionally substituted  $\text{r}$ -amino-alkyl group ( $t = 2, 3, 4$ ),  $\text{Y}_2$  is an optionally substituted amino-methylene, and both  $\text{Y}_1$  and  $\text{Y}_2$  are attached to the same ring carbon of A, the requisite acids (IV) (SCHEME 31) are prepared from the carbocyclic ketone (CIX). For example, conversion of (CIX) to the corresponding exocyclic nitrile (CX) is accomplished by treatment with TOSMIC and base as previously described. Treatment of (CX) with a base such as LDA, LHMDS or NaHMDS in a solvent such as THF and an imine, such as a *t*-butylsulphinimine (*Chemical Reviews*, (2010), **110**(6), 3600-3740) provides the *t*-butylsulphinamino-methyl substituted nitrile (CXI). Removal of the sulphinyl group by treatment with an acid such as trifluoroacetic acid in dichloromethane followed by derivatization of the primary amine as described above provides

the amino nitrile (CXII). Reduction of the nitrile (CXII) with lithium aluminum hydride, as described above, yields the primary amine (CXIII). This amine is further derivatized, where appropriate, as described above (this may also include temporary derivatization using an easily removable protecting group) to give (CXIV). Subsequent processing of the exocyclic benzyl ether in (CXIV), using the usual procedures provides the requisite acid (IV).

SCHEME 31

[00199] In the case where CycA is a 6 or 7 membered carbocycle,  $Y_1$  is an optionally substituted  $\alpha$ -amino-alkyl group ( $t = 1, 2, 3$ ),  $Y_2$  is an optionally substituted amine and the ring carbon on CycA attached to  $Y_1$  and the ring carbon on CycA attached to  $Y_2$  are separated by a methylene, the requisite acids (IV) (SCHEME 32) are prepared from an appropriately substituted carbocyclic enone such as (CXV). For example, in the case where  $t = 1$ , an appropriately functionalized one carbon unit is installed by treatment of the carbocyclic enone (CXV) with a cyanating reagent system such as trimethylsilyl cyanide or hydrogen cyanide in the presence of a base such as KF,  $Cs_2CO_3$ ,  $Bu_4NF$  or tetramethylguanidine in a suitable solvent, such as methanol, THF, DMA or acetonitrile to give (CXVI). Introduction of the nitrile can also be accomplished by treatment of the enone (CXV) with diethylaluminum cyanide in a solvent such as benzene, toluene or dichloromethane, at a temperature between about  $-20^{\circ}C$  and room

temperature. Subsequent derivitization of the carbocyclic ketone (CXVI), (via reductive amination, conversion to the azide; azide reduction and further derivitization of the resulting primary amine), as described previously, affords the 1-amino -3-cyano substituted-carbocycle (CXVII) . This intermediate is converted to the required aminomethyl derivative by reduction of the nitrile and functionalization of the resulting primary amine (CXVIII) as already described to provide (CXIX). Side chain processing in the usual manner provides (IV).

**[00200]** In the case where  $t = 2$ , or  $3$  (SCHEME 33), the appropriately functionalized carbon scaffold is prepared by treatment of the carbocyclic enone (CXV) with an allyl-silane in a non-coordinating solvent such as dichloromethane in the presence of a Lewis acid such as  $TiCl_4$ ,  $SnCl_4$ , or  $BF_3$  etherate, at a temperature between  $-78$   $^{\circ}C$  and room temperature to yield the olefin functionalized carbocyclic ketone (CXX). Processing of the ketone functionality in (CXX), as already described, yields (CXXI). Oxidative cleavage of the olefin in (CXXI) and processing of

the resulting aldehyde to the corresponding amine, as already outlined, provides (CXXII). This intermediate is then converted to the requisite acid (IV,  $t = 2$ ) by side chain processing in the usual manner. Alternatively, hydroboration of the olefin (CXXI) by treatment with a borane, such as 9-BBN in a solvent such as THF at around 0°C followed by oxidative workup (NaOH/H<sub>2</sub>O<sub>2</sub>) provides (CXXIII). Subsequent processing of (CXXIII) as already described, installs the amine functionality to give (CXXIV). Side chain processing of this intermediate yields acid (IV,  $t = 3$ ).

SCHEME 33

[00201] In the case where A is an optionally substituted 6 or 7 membered carbocycle, Y<sub>1</sub> is an optionally substituted-amine, Y<sub>2</sub> is an optionally substituted amine and the ring carbon on CycA attached to Y<sub>1</sub> and the ring carbon on CycA attached to Y<sub>2</sub> are separated by a methylene, the requisite acids (IV) (SCHEME 34) are prepared from an appropriately substituted carbocyclic enone such as (CII) by treatment with a suitable amine in the presence of a catalyst such as RuCl<sub>3</sub>, Cu(acac)<sub>2</sub>, FeCl<sub>3</sub>, Ce(NH<sub>4</sub>)NO<sub>3</sub> Pd(acac)<sub>2</sub>NH<sub>4</sub>PF<sub>6</sub> in a solvent such as water or poly-ethylene-glycol (*Green Chemistry*, (2006), 8(4), 356-358; *Synthesis*, (2005), (13), 2129-2136; *Helvetica Chimica Acta*, (2004), 87(6), 1522-1526; *Advanced Synthesis & Catalysis*, (2005), 347(6), 763-766; *Synthetic letters*, (2006), (10), 1549-1553) at a temperature between room temperature and 80°C to give the β-amino-ketone (CXXV). Subsequent processing of the ketone functionality as described above yields the diamine (CXXVI). Conversion of (CXXVI) to acid (IV) is achieved by side chain processing as previously described.

SCHEME 34

[00202] In the case where Y<sub>1</sub> is an optionally substituted amino-alkyl-oxy, the requisite acids (IV) (SCHEME 35) are prepared by treatment of an appropriate carbocyclic alcohol (CXXVII) with a phthalimido or azido substituted alkyl-halide in the presence of a base, such as sodium hydride, in a solvent such as DMF, DMA, DMSO, at a temperature between 5 °C and 80 °C ( a catalyst such as tetrabutylammonium iodide may also be used) to give the corresponding latent amino substituted alkoxy-carbocycles (CXXVIII and CXXIX) respectively. Unmasking of the latent amine by treatment of (CXXVIII) with hydrazine in ethanol, or treatment of (CXXIX) with triphenylphosphine and water in THF provides the corresponding primary amine (CXXX).

Amine derivitization as previously described yields (CXXXI). Processing of (CXXXI) by the standard method furnishes the requisite acid (IV).

SCHEME 35

[00203] Alternatively (SCHEME 36), treatment of alcohol (CXVII) with a reagent system such as iodine/imidazole/Ph<sub>3</sub>P or NBS/Ph<sub>3</sub>P or with an appropriate sulphonyl chloride (or anhydride) in the presence of a base such as pyridine or triethylamine in a solvent such as THF or dichloromethane provides the corresponding iodide, bromide or sulphonate (CXXXII). Reaction of (CXXXII) with an appropriate alcohol in the presence of a base such as sodium hydride, in a solvent such as THF, DMF, DMA, or TBTU, or a mixture thereof, provides the alkoxy substituted carbocycles (CXXVIII) and (CXXIX). Conversion of these intermediates to (IV) is carried out as already described.

SCHEME 36

**[00204]** Formula (I) provides for the case where  $Y_1$  and  $Y_2$ , taken together with the carbon atom or carbon atoms to which they are attached, form an optionally substituted carbocycle or optionally substituted heterocycle. A specific instance of this provision (SCHEME 37) is where CycA is a cyclohexane,  $Y_1$  is an (*N*-methyl- guanidinyl)-methyl group.  $Y_2$  is a methyl group.  $Y_1$  and  $Y_2$  are positioned vicinally to each other on CycA and  $Y_1$  and  $Y_2$  are linked to each other by formal fusion of two methyl groups to form a substituted piperidine. In this particular case, the requisite acids (IV) are prepared from an appropriate piperidinone such as (CXXXIII). For example, treatment of (CXXXIII) with  $\alpha$ -methyl benzylamine (*Bioorganic and medicinal Chemistry Letters*, (2008), **18**(4), 1312-1317) and an appropriate methyl-vinyl ketone derivative in toluene followed by cyclization with sodium methoxide in methanol affords the bicyclic ketone (CXXXIV). Hydrogenation of (CXXXIV) using a catalyst such as palladium on carbon in a solvent such as methanol and installation of the guanidinyl group as already described, yields ketone (CXXXV). Processing of ketone (CXXXV) as already outlined, provides the requisite acids (IV,  $M = \text{bond}$ ;  $n = 1, 2$ ). Alternatively, reduction of (CXXXV) with a hydride reducing agent such as sodium borohydride in methanol at a temperature between  $-78^\circ\text{C}$  and  $0^\circ\text{C}$  provides the corresponding alcohol which is treated with ethyl diazoacetate and a catalytic amount of  $\text{Rh}(\text{acac})_2$  dimer in a solvent such as dichloromethane to afford the ester (CXXXVI). Saponification of (CXXXVI) by brief treatment with lithium hydroxide in THF/ methanol/water provides the acid (IV,  $M = \text{O}$ ,  $n = 1$ ).

SCHEME 37

[00205] In the case where Z is a sulphonyl group (SCHEME 38), the requisite sulphonic acid is prepared from the corresponding activated carboxylic acid (V) by treatment with sodium hydroxythiopyridone in a solvent such as dichloromethane, at around room temperature to yield the Barton ester intermediate (CXXXVII). (CXXXVII) is treated with iodoform in  $\text{CCl}_4$  under a tungsten UV lamp at around reflux temperature to provide the de-carboxylative-iodination product (CXXXVIII) (*Journal of Organic Chemistry*, **75**(19), 6489-6501; 2010). Alternatively, treatment of acid (IV) with iodoso-benzene-diacetate and iodine in  $\text{CCl}_4$ , under a tungsten UV lamp, at around reflux temperature (*Journal of Organic Chemistry*, (1986), **51**, 402) provides (CXXXVIII) directly. Treatment of (CXXXVIII) with sodium sulphite in aqueous ethanol, isopropanol or acetone, at a temperature between 60 and 90°C, followed by acidification yields the sulphonic acid (IV). Alternatively, treatment of (CXXXVIII) with thiourea in acetone, at around 60 °C, provides the isothiouronium salt derivative (CXXXIX) (*Synthetic Letters*, (2010), 7, 1037). Cleavage of (CXXXVIII) with aq. sodium thiosulphate gives thiol (CXL). Treatment of (CXL) with performic acid (formic acid and aqueous  $\text{H}_2\text{O}_2$  at around 0°C to room temperature) provides (IV).

#### EXAMPLE I: Experimental Method for $\beta$ -Lactamase Enzyme Assays

##### Isolation of $\beta$ -Lactamases.

[00437] For SHV-5, Kpc-2, p99AmpC and OXA-1  $\beta$ -lactamases, *E. coli* BL21(DE3) bacterial cells carrying expression plasmids (expressed as native untagged proteins) for the individual  $\beta$ -lactamases were grown in 1L of Superbroth (Teknova Inc. Hollister, CA) supplemented with 100  $\mu$ g/ml kanamycin selection and 1x 5052 (0.5% glycerol, 0.05% glucose and 0.2%  $\alpha$ -lactose) at 35° C for 18-20 hours. Cells were harvested by centrifugation (4,000 x g, 4°C, 20 min), resuspended in 50 ml of 10 mM HEPES pH 7.5 (1/20 of the initial volume). The cells were lysed by sonication (5 pulses of 45 seconds) at 45 W on ice. The lysates were clarified by centrifugation at 10,000 x g for 40 minutes at 4°C. Samples were diluted 5-fold in 50 mM sodium acetate pH 5.0, stored overnight at 4 °C, after which they were centrifuged at 10,000 x g for 30 minutes to clarify, and filtered through 0.45  $\mu$ m filters. The samples were loaded onto a 5 ml Capto S sepharose™ cation exchange column (GE Healthcare) pre-equilibrated with 50 mM sodium acetate pH 5.0. The column was washed with 5 column volumes of 50 mM sodium acetate pH 5.0 to wash out unbound protein and a linear gradient of NaCl (0 to 500 mM) was used to elute the protein (over 16 CV) from the column. Fractions were assayed for  $\beta$ -lactamase activity using Centa (Calbiochem, Gibbstown, NJ) or Nitrocefin™ (EMD Millipore chemicals, Darmstadt, Germany) as a reporter  $\beta$ -lactamase substrate for activity in the isolated fractions. Active fractions were pooled, concentrated and further purified by gel filtration chromatography on a Superdex 75 prep grade gel filtration column (GE Healthcare, Piscataway, NJ) pre-equilibrated in 50 mM Hepes pH 7.5, 150 mM NaCl. Active fractions were pooled concentrated, quantitated by BCA protein determination (Thermo Scientific, Rockford, IL), dialyzed into PBS and frozen at -80 °C in 20% glycerol until use.

[00438] For Vim-2 metallo  $\beta$ -lactamase, the procedure was identical with the following exceptions, first the protein was not pH adjusted to pH 5 with 50 mM sodium acetate, second,

the chromatography step was changed to a 5 ml Q sepharose anion exchange column pre-equilibrated with 50 mM Hepes pH 7.5, and elution of the protein was achieved by a linear gradient of NaCl (0-600 mM). Finally, the VIM-2 purification required a second run (3<sup>rd</sup> step) on the Q sepharose anion exchange column to achieve acceptable purity (>90%).

**β-Lactamase Inhibition.**

[00439] To determine the level of inhibition of β-lactamase enzymes, compounds were diluted in PBS at pH 7.4 to yield concentrations ranging from 100 to 0.00005 μM in 96-well microtiter plates. An equal volume of diluted enzyme stock was added, and the plates were incubated at 37°C for 15 min. Nitrocefin™ was used as substrate for p99 AmpC, VIM-2 and OXA-1 and dispensed into each well at a final concentration of 100 μM. Absorbance at 486 nm was immediately monitored for 10 min using a Biotek Powerwave XS2™ microplate spectrophotometer using the GEN5™ software package (Biotek Instruments, Winooski VT). In an analogous fashion, imipenem was used as substrate for Kpc-2 and Cefotaxime was used for SHV-5, while changes in absorbance upon hydrolysis of the β-lactam ring were monitored at 300 nm and 260 nm respectively in UV-transparent 96-well microtiter assay plates. Maximum rates of hydrolysis were compared to those in control wells (without inhibitors), and percentages of enzyme inhibition were calculated for each concentration of inhibitor. The concentration of inhibitor needed to reduce the initial rate of hydrolysis of substrate by 50% (IC<sub>50</sub>) was calculated as the residual activity of β-lactamase at 486 nm using GraFit™ version 7 kinetics software package (Erihacus Software, Surrey, UK).

**EXAMPLE I: Inhibition of Diverse β-Lactamases by Exemplary Compounds**

[00440] Using the methodology described above, examples of the current invention were evaluated for their ability to inhibit β-lactamase enzymes from all four Ambler classifications (A through D). The results of these assays are summarized in Table 3 for representative enzymes across different subtypes (note SHV-5 represents an Ambler Class A Extended Spectrum β-Lactamases, KPC-2 exemplifies a Class A carbapenemase, P99 represents chromosomal Class C AmpC, OXA-1 represents a Class D oxacillinase and VIM-2 represents a class B zinc-dependent metallo-β-lactamase also possessing carbapenemase activity), where A represents an IC<sub>50</sub> of 10-100 μM, B represents an IC<sub>50</sub> of 1 to 10 μM, C represents an IC<sub>50</sub> of 0.1 to 1 μM, and D represents an IC<sub>50</sub> of < 0.1 μM. NT = Not tested.

### EXAMPLE III: In vitro Antibacterial Assays of $\beta$ -Lactamase Inhibition

[00441] To determine the ability of test compounds to potentiate the inhibition of the growth of bacterial strains that produce beta-lactamase enzymes, classic cell based broth microdilution MIC assays were employed. Six bacteria strains producing beta-lactamase enzymes were used: *E. coli* expressing the Class A Extended Spectrum Beta-Lactamase (ESBL) CTX-M-15, *E. cloacae* expressing the Class C P99, *K. pneumoniae* expressing the Class A carbapenemase KPC-2, *P. aeruginosa* expressing the Class B carbapenemase VIM-2, *K. pneumoniae* expressing the class A carbapenemase KPC-2 and the class B carbapenemase VIM-4, and *S. aureus* producing the Class A penicillinase PC-1. The assay was conducted in Cation Adjusted Mueller Hinton Broth (CAMHB, BD # 212322, BD Diagnostic Systems, Sparks, MD). Bacteria strains were grown for 3-5 hours in CAMHB broth. Test compounds were added to a microtiter plate in 2-fold serial dilutions in CAMHB in a final concentration range of 32  $\mu$ g/mL to 0.25  $\mu$ g/ml. An overlay of CAMHB containing a Beta-lactam was added to the compounds at a final static concentration of 4  $\mu$ g/ml. Ceftazidime (CAZ, Sigma# C3809-1G, Sigma-Aldrich, St. Louis, MO) was used as the partner antibiotic for *E. coli* expressing Ambler Class A ESBL CTX-M-15 (MIC alone >128  $\mu$ g/ml), and *E. cloacae* expressing Class C P99 (MIC alone = 128  $\mu$ g/mL).

Meropenem (Mero, USP # 1392454, U.S. Pharmacopeia, Rockville, MD) was used as the partner antibiotic for *K. pneumoniae* expressing Ambler Class A carbapenemase KPC-3 (MIC alone >128  $\mu$ g/mL), *P. aeruginosa* expressing Class A carbapenemase VIM-2 (MIC alone = 16  $\mu$ g/mL), and *K. pneumoniae* expressing the Ambler Class A carbapenemase KPC-2 and Ambler Class B carbapenemase VIM-4 (MIC alone = 64  $\mu$ g/mL). Piperacillin (Pip, Fisher # ICN15626801, MP Biomedicals, Solon, OH) was used as the partner antibiotic for *S. aureus* producing the Class A penicillinase PC-1 (MIC alone = 64  $\mu$ g/ml). Titration of test compounds with MIC readout indicates the concentration of test article needed to sufficiently inhibit beta-lactamase enzyme activity and protect the intrinsic antibacterial activity of the beta-lactam. In addition to the titration of test compounds the MICs of a panel of control beta-lactams is also tested to ensure the strains are behaving consistently from test to test. Once the test compound and antibiotics are added the plates can be inoculated according to CLSI broth microdilution method. After inoculation the plates are incubated for 16-20 hours at 37°C then the Minimal Inhibitory Concentration (MIC) of the test compound is determined visually.

[00442] Using the methodology described above, examples of the current invention were evaluated for their ability to inhibit the growth of  $\beta$ -lactamase-producing bacteria in the presence of a  $\beta$ -lactam antibiotic.

[00443] Representative results are shown in Table 3 where A represents an MIC >16  $\mu$ g/mL, B represents an MIC between 1 and 16  $\mu$ g /mL inclusive, and C represents an MIC of <1  $\mu$ g /mL. NT = Not Tested.

#### **EXAMPLE IV: In vitro Antibacterial Activity of Exemplary Compounds**

[00444] Using the methodology described above in EXAMPLE III, exemplary compounds for Formula I or Formula Ia were evaluated for their ability to inhibit the growth of  $\beta$ -lactamase producing bacteria in the presence of a  $\beta$ -lactam antibiotic.

[00445] Representative results are shown in Table 4 where A represents an MIC of the fixed  $\beta$ -lactam antibiotic in the presence of >32  $\mu$ g/mL of a  $\beta$ -lactamase inhibitor of exemplary compounds, B represents the MIC in the presence of between 8 and 32  $\mu$ g /mL of a  $\beta$ -lactamase inhibitor of exemplary compounds, and C represents the MIC in the presence of  $\leq$ 4  $\mu$ g /mL of a  $\beta$ -lactamase inhibitor of exemplary compounds. NT = Not Tested.
