(54) Titre : SIEGE DE SECURITE POUR ENFANT  
(54) Title: CHILD SAFETY SEAT

(57) **Abrégé/Abstract:**

The present invention is directed to an adjusting mechanism for a height adjustable headrest (1) of a child safety seat, the child safety seat comprising a seat shell (2) and a headrest (1), wherein the headrest (1) is slidably mounted to the seat shell (2) for up-and-down movement, the adjusting mechanism comprising an actuator (3) and a locking device (4), wherein the locking device (4) is configured to releasably lock the headrest (1) at a selected height, wherein the actuator (3) is configured to allow the locking device (4) to be released by actuation of the actuator (3), thus allowing the height of the headrest (i) to be adjusted, and wherein the actuator (3) is positioned between the headrest (1) and the seat shell (2) and is configured to project above the headrest (1). Preferably, the locking device (4) comprises a first component (5) mounted to the seat shell (2) and a second component (6) mounted to the headrest (1), wherein the second component (6) is configured to releasably engage with the first component (5).

## Abstract

**Child Safety Seat**

5 The present invention is directed to an adjusting mechanism for a height adjustable headrest (1) of a child safety seat, the child safety seat comprising a seat shell (2) and a headrest (1), wherein the headrest (1) is slidably mounted to the seat shell (2) for up-and-down movement, the adjusting mechanism comprising an actuator (3) and a locking device (4), wherein the locking device (4) is configured to releasably lock the headrest (1) at a selected height, wherein the  
10 actuator (3) is configured to allow the locking device (4) to be released by actuation of the actuator (3), thus allowing the height of the headrest (1) to be adjusted, and wherein the actuator (3) is positioned between the headrest (1) and the seat shell (2) and is configured to project above the headrest (1). Preferably, the locking device (4) comprises a first component (5) mounted to the seat shell (2) and a second component (6) mounted to the headrest (1), wherein the second  
15 component (6) is configured to releasably engage with the first component (5).

## Child Safety Seat

5

The present invention relates to an adjusting mechanism for a height adjustable headrest of a child safety seat and to a child safety seat comprising such an adjusting mechanism.

10

Child safety seats are employed for the safe transport of children in vehicles. Many of these child safety seats comprise a headrest which is intended to protect the child's head. To achieve a high level of protection it is important that the headrest is suitably positioned in the child safety seat with respect to the child's head. Since a child safety seat is usually used over a period of several months or years, during which period a child will experience significant growth, it has become common practice to provide a child safety seat with a height adjustable headrest. In such a child safety seat the height of the headrest can be adjusted to the needs of a specific child.

15

Since the headrest of a child safety seat has a significant influence on the level of protection the child safety seat is able to provide, it is obvious that there is a need for a reliable and easily operated adjusting mechanism for the headrest of a child safety seat. Parents and other

20 caregivers may be reluctant to constantly adjust the headrest to the proper height if the mechanism is complicated to operate or if there could be doubts as to whether the headrest has been properly secured in the new position.

20

Therefore, it is an object of the present invention to provide a reliable adjusting mechanism for a

25 height adjustable headrest of a child safety seat which is easily operated.

25

This object is solved by the adjusting mechanism in accordance with the present invention with the features of claim 1. Advantageous embodiments of the present invention are indicated in dependent claims 2-10.

30

The present invention is directed to an adjusting mechanism for a height adjustable headrest of a child safety seat, the child safety seat comprising a seat shell and a headrest, wherein the headrest is slidably mounted to the seat shell for up-and-down movement. The adjusting mechanism in accordance with the invention comprises an actuator and a locking device, wherein the locking

35 device is configured to releasably lock the headrest at a selected height, wherein the actuator is configured to allow the locking device to be released by actuation of the actuator, thus allowing

35

the height of the headrest to be adjusted, and wherein the actuator is positioned between the headrest and the seat shell and is configured to project above the headrest.

When the locking device is locked, the headrest is fixed at a specific height or position. In order  
5 to adjust the height of the headrest, i.e. to slide the headrest to another position, the locking  
device has to be unlocked. This can be achieved by actuating the actuator. As soon as the locking  
device is released or unlocked, the headrest can be repositioned. By positioning the actuator  
between the headrest and the seat shell and by having the actuator project above the headrest it  
can be ensured that the actuator is always easily accessible. Since the actuator is positioned  
10 between the headrest and the seat shell, the actuator is positioned in front of the seat shell, not  
behind the seat shell. Therefore, with this actuator, there is no need to reach to the back of the  
child safety seat (as with actuators that are positioned on the back of the backrest of the child  
safety seat) in order to adjust the headrest. Furthermore, since the actuator projects above the  
headrest, there is no need to have access to the possibly narrow space between headrest and seat  
15 shell in order to reach the actuator. As a result, the adjusting mechanism is operable from the  
front of the child safety seat and is operable with one hand.

Advantageously, the locking device comprises a first component mounted to the seat shell and a  
second component mounted to the headrest, wherein the second component is configured to  
20 releasably engage with the first component. With these two components, one being mounted to  
the seat shell, the other one being mounted to the headrest, the headrest's position relative to the  
seat shell can be reliably locked. Since the second component is configured to releasably engage  
with the first component, the headrest's position will not be permanently locked. Instead, the  
locking can be released by disengaging the second component from the first component.

25 Instead of being mounted to the seat shell, the first component may be formed integrally with the  
seat shell. This might reduce manufacturing costs of a child safety seat comprising an adjusting  
mechanism in accordance with the invention.

30 Preferably, the first component comprises a toothed rack and the second component comprises a  
locking lever and an axle, wherein the locking lever is pivotally mounted to the headrest and the  
axle is adapted to be disengaged from the toothed rack by pivoting of the locking lever in order  
to unlock the locking device. When the axle engages with the toothed rack, the locking device is  
locked. The locking device can be unlocked by pivoting the locking lever so that the axle is  
35 disengaged from the toothed rack. By making use of a toothed rack a number of locking positions  
can be defined for the headrest. Each recess positioned between two adjacent teeth of the toothed

rack corresponds to one possible position of the headrest. The headrest is locked in a specific position by inserting the axle in the recess of the toothed rack corresponding to this specific position. By adjusting the configuration of the toothed rack (e.g., number of teeth/recesses, size of teeth/distance between adjacent recesses) the possible positions of the headrest can be  
5 configured.

Advantageously, the actuator is coupled to the locking lever such that by pushing the actuator downwards the locking lever is configured to pivot in order to disengage the axle from the toothed rack. Thus, by pushing the actuator downwards, the locking device can be released. As  
10 soon as the locking device is released, the headrest can be repositioned. To lower the headrest, it is sufficient to continue pushing the actuator downwards. Therefore, with this configuration of the adjusting mechanism of the invention, lowering the headrest of the child safety seat is a very straightforward and intuitive process: pushing the actuator downwards is all one needs to do in order to lower the headrest.

15 Advantageously, the teeth of the toothed rack are shaped to allow the axle to automatically snap from one position to another position when the actuator or the headrest is being pulled upwards. To give the teeth of the toothed rack such a shape is advantageous since with this shape of the teeth, in order to raise the headrest, it will not be necessary to release the locking device by  
20 pushing the actuator downwards. Instead, the locking device will be automatically released as the headrest or the actuator is being pulled upwards. Thus, raising the headrest of the child safety seat will also be intuitive: the headrest can be raised simply by pulling the actuator or the headrest upwards. There is no need to separately release or unlock the locking device.

25 Advantageously, the adjusting mechanism of the invention furthermore comprises a biasing member configured to bias the axle into engagement with the toothed rack. With this biasing member it can be ensured that in the rest configuration of the adjusting mechanism, i.e. without actuation of the actuator, the locking device is locked. In the rest configuration the axle is held in engagement with the toothed rack by the biasing member. To disengage the axle from the  
30 toothed rack, i.e. to unlock the locking device, the biasing force exerted on the axle by the biasing member has to be overcome.

Advantageously, the toothed rack is shaped so that the axle is prevented from being forced out of a recess positioned between two adjacent teeth of the toothed rack by pushing the headrest  
35 downwards, whereas the axle is free to slide out of the recess when the headrest is being pulled upwards. This ensures that in order to lower the headrest, the actuator has to be actuated so that

the locking device gets released, i.e. the axle is disengaged from the toothed rack, whereas in order to raise the headrest, there is no need to release the locking device by actuating the actuator. Instead, the locking device will be automatically released as the headrest is being raised. Thus, the headrest may be lowered or raised in a very convenient way.

5

According to another aspect of the invention, there is provided a child safety seat comprising the adjusting mechanism described above.

Advantageously, the child safety seat furthermore comprises an internal harness system  
10 comprising shoulder straps, wherein the shoulder straps are routed over the axle. By routing the shoulder straps over the axle, forces acting on the shoulder straps during a crash of the vehicle carrying the child safety seat can be employed to further secure the position of the headrest of the child safety seat. The shoulder straps can be made to press the axle to the toothed rack, thus preventing the axle from disengaging from the toothed rack.

15

Overall, the adjusting mechanism of the invention is designed to allow the mechanism to be operable from the front of the child safety seat, to be operable with one hand, to be intuitive for a user, and to be running smoothly.

20

According to another aspect of the invention an adjusting mechanism for a height adjustable headrest of a child safety seat is provided, the child safety seat comprising a seat shell, a headrest, an actuator, and a locking device, wherein the headrest is slidably mounted to the seat shell for up-and-down movement, the locking device is configured to releasably lock the headrest at a selected height, and the actuator is configured to allow the locking device to be released by  
25 actuation of the actuator, thus allowing the height of the headrest to be adjusted.

25

According to another aspect of the invention an adjusting mechanism for a height adjustable headrest of a child safety seat is provided, the child safety seat comprising a seat shell and a headrest, wherein the headrest is slidably mounted to the seat shell for up-and-down movement,  
30 the adjusting mechanism comprising an actuator and a locking device, wherein the locking device is configured to releasably lock the headrest at a selected height, and wherein the actuator is configured to allow the locking device to be released by actuation of the actuator, thus allowing the height of the headrest to be adjusted, wherein the locking device comprises a locking lever which is pivotally mounted to the headrest and an axle which is connected to the locking lever,  
35 wherein the locking device furthermore comprises a toothed rack which is mounted to the seat shell and wherein the axle is configured to releasably engage with the toothed rack in order to

releasably lock the headrest, wherein the axle is adapted to be disengaged from the toothed rack by pivoting of the locking lever in response to a downward force acting on the actuator in order to unlock the locking device.

5 Specific embodiments of the invention will now be described by way of example and with reference to the accompanying drawings, in which:

Fig. 1 is an exploded view of a child safety seat comprising an adjusting mechanism for a height adjustable headrest in accordance with an embodiment of the invention;

Fig. 2 is a rear view of the child safety seat of Fig. 1;

10 Fig. 3a is a sectional view of the child safety seat of Fig. 1, with the height adjustable headrest locked in the uppermost position;

Fig. 3b is a sectional view similar to Fig. 3a, with the height adjustable headrest unlocked for adjustment of its height;

15 Fig. 3c is a sectional view similar to Fig. 3b, with the height adjustable headrest pushed to a lower position;

Fig. 3d is a sectional view similar to Fig. 3c, with the height adjustable headrest locked in a lower position;

Fig. 4a is a sectional view similar to Fig. 3d, with the height adjustable headrest locked in a lower position;

20 Fig. 4b is a sectional view similar to Fig. 4a, with the height adjustable headrest slightly raised from the position of Fig. 4a, thereby unlocking a locking device;

Fig. 4c is a sectional view similar to Fig. 4b, with the height adjustable headrest raised higher, the locking device still unlocked;

25 Fig. 4d is a sectional view similar to Fig. 4c, with the height adjustable headrest locked again in the uppermost position;

Fig. 5a is a detailed view of the adjusting mechanism of the previous Figures; and

Fig. 5b is another detailed view of the same adjusting mechanism.

30 Fig. 1 shows a child safety seat comprising an adjusting mechanism for a height adjustable headrest 1 in accordance with an embodiment of the invention. The child safety seat comprises a seat shell 2, a height adjustable headrest 1, an actuator 3, and a locking device 4. The headrest 1 is slidably mounted to the seat shell 2 for up-and-down movement. The seat shell 2 comprises a backrest portion and a seating portion. The headrest 1 is coupled to the backrest portion of the seat shell 2. The adjusting mechanism furthermore comprises a locking device 4. The locking device 4 is configured to releasably lock the position of the headrest 1.

35

The locking device 4 comprises a first component 5 and a second component 6. In the embodiment of the invention shown in Fig. 1 the first component 5 comprises a toothed rack 7 which is fixedly mounted to the back of the backrest portion of the seat shell 2. In an alternative embodiment of the invention, the toothed rack 7 is integrally formed with the seat shell 2. The second component 6 of the locking device 4 comprises a locking lever 8 and an axle 9. The locking lever 8 is pivotally mounted to the headrest 1 by two pins 12 and is configured to pivot about the pivot axis defined by the pins 12. The axle 9 is fixedly mounted to the locking lever 8 and is adapted to engage with the toothed rack 7 in order to lock the headrest 1 in a selected position. To unlock the headrest 1, the axle 9 is disengaged from the toothed rack 7. This is achieved by pivoting the locking lever 8 about the pivot axis.

The adjusting mechanism shown in Fig. 1 furthermore comprises a biasing member in the form of a spring 11. This spring 11 is coupled to the locking lever 8 and to the headrest 1. The spring 11 forces the axle 9 into engagement with the toothed rack 7 as will become more apparent in subsequent Figures. The adjusting mechanism furthermore comprises an actuator 3 which is positioned between the headrest 1 and the seat shell 2 and which is configured to project above the headrest 1. The actuator 3 is configured to allow the locking device 4 to be released by actuation of the actuator 3.

The adjusting mechanism furthermore comprises a cover 13 which is configured to partly cover the locking lever 8 and which is mounted to the headrest 1 by two screws 14. Furthermore, the cover 13 is configured to prevent the headrest 1 from being detached from the child safety seat.

Fig. 2 shows a rear view of the child safety seat of Fig. 1. In this view the axle 9 engages with the toothed rack 7, thus locking the headrest 1 in the uppermost position. As can be clearly seen in this view, the actuator 3 is configured to project above the headrest 1. Therefore, the actuator can be easily reached by a user of the child safety seat, even from the front of the seat.

The process of lowering the headrest 1 with the adjusting mechanism of the invention is shown in Figs. 3a-d.

Fig. 3a is a sectional view of the child safety seat of Figs. 1 and 2. The height adjustable headrest 1 is locked in the uppermost position. Again, the actuator 3 can be seen to project above the headrest 1. The tension spring 11 is coupled to the locking lever 8 and to the headrest 1 and is configured to generate a torque to pivot the locking lever 8 about the pivot axis defined by the pins 12 in the clockwise direction. Since the axle 9 is coupled to the locking lever 8 below the

pins 12, this torque forces the axle 9 into engagement with the toothed rack 7. To release the locking device 4 of the adjusting mechanism in accordance with the invention, the actuator 3 is pushed downwards.

5 This is shown in Fig. 3b. Here, the actuator 3 has been pushed downwards in the direction indicated by arrow 16. When the actuator 3 is pushed downwards, it generates another torque on the locking lever 8 which counteracts the torque generated by the spring 11. If the torque generated by the actuator 3 exceeds the torque generated by the spring 11, the locking lever 8 will be pivoted about the pivot axis defined by the pins 12 in the counter-clockwise direction,  
10 thus removing the axle 9 from the toothed rack 7 in the direction indicated by arrow 17. As soon as the axle 9 is disengaged from the toothed rack 7, the headrest 1 is free to move downwards in the direction indicated by arrow 15. Therefore, pushing the actuator 3 down will first release the locking device 4 and will then push the headrest 1 down to a lower position.

15 In Fig. 3c the headrest 1 has reached the lower position. The axle 9 is still disengaged from the toothed rack 7. Therefore, if the downward force 16 on the actuator 3 would continue to be applied, the headrest 1 would continue to be lowered in the direction indicated by arrow 15. To lock the headrest 1 in the lowered position, the actuator 3 has to be released. When the actuator 3 is released, the actuator 3 will no longer generate a torque on the locking lever 8. Therefore,  
20 the spring 11 will again bring the axle 9 into engagement with the toothed rack 7, now locking the headrest in the lowered position.

This is shown in Fig. 3d where the locking lever 8 has been pivoted about the pins 12 in the direction indicated by arrow 18. This clockwise rotation of the locking lever 8 brings the axle 9  
25 back into engagement with the toothed rack 7 and pushes the actuator 3 upwards so that the actuator 3 again projects above the headrest 1.

The process of raising the headrest 1 with the adjusting mechanism of the invention is shown in Figs. 4a-d.

30

Fig. 4a shows the headrest 1 locked in the lowered position of Fig. 3d. To raise the headrest 1, the actuator 3 can be pulled upwards in the direction indicated by arrow 20 in Fig. 4b, or the headrest 1 itself can be pulled upwards in the direction indicated by arrow 19 in Fig. 4b. The actuator 3 is coupled to the headrest 1 in such a way that by pulling the actuator 3 upwards, the  
35 actuator 3 loses contact with the locking lever 8. When the headrest 1 is pulled upwards, the locking lever 8 which is coupled to the headrest 1 will also be pulled upwards. The teeth 10 of the

toothed rack 7 are shaped such that when the locking lever 8 is pulled upwards, the axle 9 is pushed out of the recess between two teeth by sliding on the edge of the tooth positioned above the axle 9.

5 This is shown in Fig. 4b. Actuator 3 is pulled upwards in the direction indicated by arrow 20, thus raising the headrest 1 in the direction indicated by arrow 19. By this, locking lever 8 is also raised. Thus, axle 9 slides on the edge of the tooth positioned above axle 9. As a result, the locking lever 8 begins to pivot about the pivot axis defined by the pins 12 in the direction indicated by arrow 17, against the force of the tension spring 11.

10

When the headrest 1 is raised further in the direction indicated by arrow 19, as shown in Fig. 4c, the locking lever 8 continues to pivot about the pins 12 in the direction indicated by arrow 17 until the axle 9 has reached the top of a tooth of the toothed rack 7. When the headrest 1 is then still raised further, the axle 9 will snap into the next recess positioned between two teeth of the  
15 toothed rack 7, thus locking the headrest in a raised position.

This is shown in Fig. 4d. The locking lever 8 is pivoted about the pins 12 by the tension spring 11 so that the axle 9 is brought into engagement with the toothed rack 7. The headrest 1 is locked again.

20

Fig. 5a shows the toothed rack 7 of an adjusting mechanism in accordance with the invention in more detail. The toothed rack 7 comprises a plurality of teeth 10. Each pair of adjacent teeth 10 defines a recess 10a positioned between these teeth 10. The recesses 10a are configured to receive the axle 9. The locking lever 8 is configured to pivot about the pivot axis defined by the pins 12.

25

In the configuration shown in Fig. 5a the headrest 1 is locked since the axle 9 engages with the toothed rack 7. In particular, the axle 9 is positioned in a recess 10a. The headrest 1 cannot be lowered simply by pushing the headrest 1 downwards in the direction indicated by arrow 15.

30

When the headrest 1 is pushed downwards in the direction indicated by arrow 15, a force will be exerted on the axle 9 acting in the direction indicated by arrow 15a. This is due to the fact that the axle 9 is positioned in front of the pins 12. In other words, the pivot axis defined by the pins 12 is placed behind the toothed rack 7. Due to the specific shape of the teeth 10 of the toothed rack 7, the force acting on the axle 9 in the direction of arrow 15a locks the axle 9 in the recess 10a. Thus, the headrest 1 cannot be lowered without releasing the locking device 4 first by actuation of the actuator 3.

35

Fig. 5b is similar to Fig. 5a but shows in addition a strap of a harness 22. This harness strap 22 may be a shoulder belt of the internal harness system of a child safety seat in accordance with the invention. The harness strap 22 is routed over the axle 9. When a force is exerted on the harness strap 22 in the direction of arrow 23 (e.g. in the course of an accident), the axle 9 will receive a  
5 force acting in the direction of arrow 24. This force will press the axle 9 further into the recess 10a, thus safely locking the headrest 1 in the selected position.

## List of reference numerals:

- |    |     |  |

## Claims

1. An adjusting mechanism for a height adjustable headrest (1) of a child safety seat, the  
5 child safety seat comprising a seat shell (2) and a headrest (1), wherein the headrest (1) is slidably  
mounted to the seat shell (2) for up-and-down movement,  
the adjusting mechanism comprising an actuator (3) and a locking device (4), wherein  
the locking device (4) is configured to releasably lock the headrest (1) at a selected height,  
wherein the actuator (3) is configured to allow the locking device (4) to be released by  
10 actuation of the actuator (3), thus allowing the height of the headrest (1) to be adjusted, and  
wherein the actuator (3) is positioned between the headrest (1) and the seat shell (2) and  
is configured to project above the headrest (1).
2. The adjusting mechanism of claim 1, wherein the locking device (4) comprises a first  
15 component (5) mounted to the seat shell (2) and a second component (6) mounted to the headrest  
(1), wherein the second component (6) is configured to releasably engage with the first  
component (5).
3. The adjusting mechanism of claim 1, wherein the locking device (4) comprises a first  
20 component (5) formed integrally with the seat shell (2) and a second component (6) mounted to  
the headrest (1), wherein the second component (6) is configured to releasably engage with the  
first component (5).
4. The adjusting mechanism of claim 2 or 3, wherein the first component (5) comprises a  
25 toothed rack (7) and the second component (6) comprises a locking lever (8) and an axle (9),  
wherein the locking lever (8) is pivotally mounted to the headrest (1) and the axle (9) is adapted  
to be disengaged from the toothed rack (7) by pivoting of the locking lever (8) in order to unlock  
the locking device (4).
- 30 5. The adjusting mechanism of claim 4, wherein the actuator (3) is coupled to the locking  
lever (8) such that by pushing the actuator (3) downwards the locking lever (8) is configured to  
pivot in order to disengage the axle (9) from the toothed rack (7).
6. The adjusting mechanism of claim 4 or 5, wherein the teeth of the toothed rack (7) are  
35 shaped to allow the axle (9) to automatically snap from one position to another position when the  
actuator (3) or the headrest (1) is being pulled upwards.

7. The adjusting mechanism of any one of claims 4 to 6, furthermore comprising a biasing member (11) configured to bias the axle (9) into engagement with the toothed rack (7).

5 8. The adjusting mechanism of any one of claims 4 to 7, wherein the toothed rack (7) is shaped so that the axle (9) is prevented from being forced out of a recess (10a) positioned between two adjacent teeth (10) of the toothed rack (7) by pushing the headrest (1) downwards, whereas the axle (9) is free to slide out of the recess (10a) when the headrest (1) is being pulled upwards.

10

9. A child safety seat comprising the adjusting mechanism of any one of the previous claims.

10. A child safety seat comprising the adjusting mechanism of any one of claims 4 to 8, the child safety seat furthermore comprising an internal harness system comprising shoulder straps,  
15 wherein the shoulder straps are routed over the axle (9).
