CYCLIC PEPTIDE WITH ANTI-METASTASIS ACTIVITY

BACKGROUND

Malignant cells, with laminin receptors on their surfaces, bind and attach more readily to laminin than normal cells. Malignant cell invasiveness involves binding to laminin and the use of specific mechanisms including the production of proteolytic enzymes and the movement of the cells into normal tissues. This process involves the degradation of the basement membrane.

Peptides which have been shown to exhibit inhibition of tumor cell metastasis include the pentapeptide tyrosine-isoleucine-glycine-serine-arginine, as disclosed in European Patent Application Publication No. 0278781. Iwamoto, Y. et al., Science 238:1132 (1987) and Graf, J. et al., Biochemistry 26:6896 (1987). It would be desirable to discover other effective peptides capable of inhibiting tumor cell invasiveness by inhibiting cell attachment to laminin.

BRIEF DESCRIPTION OF THE FIGURES

FIG. 1 In vitro cell attachment assays showing the cyclic peptide of the invention having higher affinity for cell adhesion than the straight chain peptide.

FIG. 2 In vivo antimetastatic data showing the cyclic peptide of the invention is at least twice as effective as linear YIGSR-NH₂.

SUMMARY OF THE INVENTION

It has been discovered that a cyclic peptide having the formula:

\[
\text{HNYIGSK'C=O}
\]

or a pharmaceutically acceptable salt thereof, exhibits antimetastatic activity. The peptide blocks cell adhesion, laminin-mediated adhesion and melanoma cell colonization. The peptide also elutes the laminin receptor from laminin affinity columns and binds the 67 kd laminin receptor. The peptide should be effective in blocking attachment and metastasis of a variety of cell types including breast carcinoma, epidermal carcinoma, muscle line melanoma, epidermal line neuroblastoma x glioma, chondrocytes, human skin fibroblasts, bovine osteoeblasts and fibroblasts.

The one-letter symbols "Y", "I", "G", "S" and "R" refer to the amino acids L-tyrosine, L-isoleucine, L-glycine and L-serine, and L-arginine, respectively, and R' refers to D-arginine. The line in the cyclic structure depicts the bond between the amino terminal group of L-tyrosine and the carboxy terminal group of D-arginine. Non-toxic pharmaceutical salts may be prepared by reaction of the cyclic peptide with inorganic or organic acids. The resulting salts maintain the biological activity of the cyclic peptide. Examples of satisfactory acids are hydrochloric acid, nitric acid, phosphoric acid, tartaric acid and acetic acid.

The peptide of this invention interacts with the laminin receptors on a malignant cell so that it cannot bind to laminin, thereby blocking the binding of the malignant cell to laminin and inhibiting the destructive invasiveness of the malignant cell. The peptide of the invention acts by blocking cell adhesion and blocking laminin-mediated adhesion.

A straight chain peptide of the invention is synthesized, using the L form of amino acids except for arginine in which the D form is used, by the classical solid phase synthesis procedure of Merrifield, J. Am. Chem. Soc. 85:2149 (1963) as described by Stewart and Young (Solid Phase Peptide Synthesis, 2nd Ed. (1984), Pierce Chemical Company, Rockford, Ill.). Alternatively, the straight chain peptide may be synthesized with all L-amino acids and the L-arginine converted to D-arginine by racemization. The peptide of the invention is then prepared by cyclization of the straight chain peptide as described below.

Cyclization of the straight chain peptide is accomplished by producing the acid form of the peptide and then making the active ester with subsequent coupling with a suitable dehydrating such as dicyclohexylcarbodiimide, or diisopropylcarbodiimide. The carboxy terminal arginine of the straight chain peptide must be D-arginine for cyclization to occur. The use of the straight chain peptide with L-arginine does not result in cyclization, absent racemization of the L-arginine to the D-arginine form. Only straight chain peptides with D-arginine can obtain the proper conformation to allow for cyclization to occur. Cyclization generally imparts stability to peptides by rendering the peptide less susceptible to proteolytic degradation and imparts to it a longer half life. Thus, cyclization of small peptides allows them to be taken orally and not be degraded before absorption.

The cyclic peptide of the invention may be used in a variety of therapeutic and pharmaceutical applications relating to malignant tumor cells. Typically, the cyclic peptide is administered as a pharmaceutical composition comprising an excipient. The pharmaceutical compositions may be prepared by any of the known procedures as described in Remington's Pharmaceutical Sciences, Mack Publishing Company, Eaton, PA 16th Ed., 1980.

Excipients may include sterile water, saline solution and buffered saline including buffers like phosphate or acetate, sodium chloride or sucrose as pressure adjusting agents, and antioxidants such as ascorbic acid, or any acceptable combinations thereof. The pharmaceutical composition may be in various forms like tablets and solutions and be administered by various routes including orally, nasally, and parenterally (including intravenously, intramuscularly, subcutaneously and intraperitoneally). The dose range will vary depending on variables like the patient's age, weight, condition, and route of administration. Typically, dose range is from 0.001 to 100 mg of active substance per kilogram body weight. Preferably the range is from 0.01 to 50 mg of active substance per kilogram body weight.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The following examples illustrate specific embodiments of the invention described herein.
EXAMPLE 1

The Tyrosine-Isoleucine-Glycine-Serine-Arginine (YIGSR) peptide, using L-amino acids, is synthesized by the classical solid phase synthesis procedure of Merrifield (J. Am. Chem. Soc. 85, 2149-54 (1963) as described by Stewart and Young (Solid Phase Peptide Synthesis, 2nd Ed. (1984) Pierce Chemical Co., Rockford, II) on an automated Model Applied Biosystems synthesizer. Deprotection and release of the peptide from the solid-phase support matrix is accomplished by treating the protected peptide on the resin with anhydrous HF containing 10% anisole for 1-2 hours at 0°C. Deprotection reagents are removed by extraction with ethyl acetate, the peptide dissolved in 30% aqueous acetic acid, and the solution is filtered through a sintered glass (coarse) Buchner funnel to remove the resin. After lyophilization, the peptides are purified via semi-prep high-pressure liquid chromatography (HPLC; reverse phase C18, 25 cm x 9.6 mm, Vydac, Hesperia, Calif.). Cyclization is accomplished by producing the active ester (N-hydroxysuccinimide, 3 x molar ratio) of the free acid peptide (0.5 mM) and subsequent coupling using disopropylcarbodiimide (DIC, 1.1 x molar ratio) in anhydrous dimethylformamide (DMF) as solvent. The pH is maintained at ~7.5 by addition of triethylamine and the reaction is stirred at room temperature for 3 weeks under a stream of nitrogen. The cyclic peptide of the invention is purified by semi-prep reverse phase HPLC on C18 (Vydac, Hesperia, Calif.).

EXAMPLE 2

HT-1080 cells from a human fibrosarcoma (Rasheed, S. et al., Cancer (Philadelphia) 33:1027 (1974) are maintained in Dulbecco’s modified Eagle’s medium (DMEM) supplemented with 10% fetal calf serum. After the cells are grown to 80% confluency, they are washed with 0.02M phosphate buffer, pH 7.4, without Ca²⁺ and Mg²⁺ and detached with a solution of 0.025% trypsin plus 0.025% ethylenediaminetetraacetic acid (EDTA; Gibco). The cells are then pelleted by low speed centrifugation and resuspended in Eagle’s minimal essential medium (EMEM) containing 0.02% bovine serum albumin (BSA, Sigma Chemical Co., St. Louis, Mo.). Cell attachment assays are performed as described in Klebe, R.J. Nature (London) 250:248 (1974), on tissue culture plastic substrates by using 16-mm Falcon tissue culture wells (Fisher Scientific Co., Pittsburgh, Pa.) incubated with various peptides or with laminin in mL of EMEM containing 0.02% BSA for 1 or 2 hours at 37°C. Cells (10⁵ in 0.1 mL) are added to the wells, and the solution is incubated for an additional 1 hour at 37°C in 95% air and 5% CO₂. Subsequently, the wells are rinsed 3 times with mL of phosphate-buffered saline (PBS) to remove unattached cells. Attached cells are trypsinized and counted electronically (Coulter, ZBI). The attachment assays are carried out in the presence of cycloheximide (25 mg/mL) to minimize the production of endogenous attachment proteins. Each peptide is tested in duplicate dishes and each assay is repeated 6 times. The variation between samples in different assays is <15%.

To test the inhibition of attachment to laminin by the peptides, bacteriologically petri dishes (35mm) are coated with 5 mg of laminin which is allowed to air-dry onto the dishes overnight. Prior to the addition of the cells, varying concentrations of the peptide solubilized in serum-free EMEM containing 0.05% BSA are added to each dish. The attachment assay is then carried out as above. Each dish contained a final volume of 1.0 mL and each assay is performed in duplicate with each peptide assayed nine times. In vitro cell attachment assays, as shown in FIG. 1, show the cyclic peptide of the invention having higher affinity for cell adhesion than the straight chain peptide.

EXAMPLE 3

B16F10 melanoma cells, obtained from I.J. Fidler, M.D., Anderson Hospital, Houston, TX, are propagated under standard culture conditions. The lung tumor colonization assay is carried out as described in Fidler, I.J., Nature (London) (New Biol.) 242:148 (1973). Peptides are dissolved at 5 mg/mL in PBS and are filter-sterilized. The suspension of B16F10 cells (5.10⁵) in 0.1 mL of DMEM is mixed with 0.1 mL of the peptide (or 1 mL PBS in control), incubated for 5 minutes at room temperature, and then injected into the tail vein of syngeneic C57BL/6 female mice (Jackson Labs., Bar Harbor, Me.) at 6 weeks of age. Each treatment and control group consists of eight mice. Three weeks after the injections, the mice are killed and the number of pulmonary tumors on the surface of the lungs counted.

FIG. 2, depicting the in vivo antimetastatic data, shows that the cyclic peptide of the invention is at least twice as effective as linear YIGSR-NH₂. Although the invention has been described with respect to specific modifications, the details thereof are not to be construed as limitations, for it will be apparent that various equivalents, changes and modifications may be resorted to without departing from the spirit and scope thereof and it is understood that such equivalent embodiments are to be included therein.

What is claimed is:

1. A peptide of the formula:

   HNYIGSR'C=O

   or a pharmaceutically acceptable salt thereof in which YIGSR and R' are L-tyrosine, L-isoleucine, L-glycine, L-serine and D-arginine, respectively.

2. The peptide of claim 1 of the formula:

   HNYIGSR'C=O.

3. The peptide of claim 1 which is a pharmaceutically acceptable salt of the peptide of the formula:

   HNYIGSR'C=O.

4. A pharmaceutical composition comprising a pharmaceutically acceptable excipient and a therapeutically effective amount of a peptide of the formula:

   HNYIGSR'C=O

   or a pharmaceutically acceptable salt thereof in which YIGSR and R' are L-tyrosine, L-isoleucine, L-glycine, L-serine and D-arginine, respectively.

5. The pharmaceutical composition of claim 4 in which the peptide is of the formula:

   HNYIGSR'C=O.
6. The pharmaceutical composition of claim 4 in which the peptide is a pharmaceutically acceptable salt of the peptide of the formula:

\[
\text{HNYYGSR}C=O
\]

7. A method for inhibiting metastasis in a patient which comprises administering an effective amount of a peptide of the formula:

\[
\text{HNYYGSR}C=O
\]

or a pharmaceutically acceptable salt thereof in which Y.I.G.S. and R' are L-tyrosine, L-sioleucine, L-glycine, L-serine and D-arginine, respectively.

8. The method of claim 7 in which the peptide is of the formula:

\[
\text{HNYYGSR}C=O
\]

9. The method of claim 7 in which the peptide is a pharmaceutically acceptable salt of the peptide of the formula:

\[
\text{HNYYGSR}C=O
\]

10. The method of claim 8 in which the peptide is administered as a pharmaceutical composition comprising a pharmaceutically acceptable excipient.

11. The method of claim 9 in which the peptide is administered as a pharmaceutical composition comprising a pharmaceutically acceptable excipient.
