The text in the image is a patent document that describes a friction drive material handling system. The system includes a composite beam and a method of operating the same. It uses a drive tube and a plurality of spaced apart transverse members to drive a trolley. The system is configured to rotate the drive tube. The patent is filed with the International Patent Cooperation Treaty (PCT) and published by the World Intellectual Property Organization (WIPO). The inventors are David Spangler, Janda, M., et al., and the assignee is Caterpillar Inc. The priority date is 19 January 2010, and the filing date is 26 February 2010. The patent number is WO 2010/080982 A2. The abstract is as follows:

A material handling system (250) includes a composite beam (252) including an upper rail (254) and a lower track (256) connected through a plurality of spaced apart transverse members (258). A trolley (262) includes an upper set of wheels (266) and a lower set of wheels (264). The lower set of wheels (264) is received within two parallel channels (260) defined by the lower track (256). A drive tube (268) is positioned between the upper rail (254) and the lower track (256) such that the upper set of wheels (266) are in frictional engagement with the drive tube (268). A drive system (270) is configured to rotate the drive tube (268).
Description

FRICITION DRIVE MATERIAL HANDLING SYSTEM INCLUDING COMPOSITE BEAM AND METHOD OF OPERATING SAME

5 Technical Field

The present disclosure relates generally to a material handling system, and more particularly to a friction drive material handling system including a composite beam.

Background

10 During a manufacturing process, a product is typically advanced through a plurality of manufacturing stations of a manufacturing chain. Specifically, the product is transported through each of the manufacturing stations along an article transportation device. At each manufacturing station, a specific one of a plurality of tasks in the manufacturing process is performed. All equipment and other components necessary to perform the assigned task are positioned, and often permanently affixed, at each manufacturing station. As a result, and dependent upon the number of tasks and the complexity of the manufacturing process, a manufacturing chain is typically a large structure that is permanently situated inside a manufacturing facility.

15 At least partially as a result of its permanency, a manufacturing chain is typically inflexible, such that modifying, removing, or replacing the manufacturing chain may be an expensive and time-consuming process. Therefore, even minor improvements to the manufacturing process, such as, for example, changes to the equipment positioned at one manufacturing station, may be too expensive and time consuming to implement. Further, if the manufacturing process performed by the manufacturing chain becomes unnecessary, it may not be feasible to alter the manufacturing chain to perform a
different manufacturing process. Ultimately, the manufacturing chain may only be cost effective in performing the specific manufacturing process for which it was designed. As a result, the significant amount of costs and efforts to design and construct the manufacturing chain may be wasted.

Another drawback with conventional manufacturing chains involves the article transportation system along which the products are transported. Since the products are typically carried along one article transportation device having a single driving source, such as a common monorail conveyor, the entire manufacturing chain must be stopped in order to correct a problem occurring at any point along the manufacturing chain. Power and free conveyors offer one solution by allowing carriers to be routed off of the main line, such as if a defect is identified, but still provide continuous movement of the main line. In either case, stopping the main line can result in significant down time and, therefore, reduced efficiency and, ultimately, throughput of the manufacturing chain. This may further increase process time for manufacturing processes that already require a significant amount of time. For example, it is known that a drying or curing stage of a paint process may require a significant amount of time, thus greatly increasing the minimal process time for the manufacturing process.

U.S. Patent No. 6,120,604 teaches a powder coating chain having a plurality of conveyors for transporting parts through a plurality of processing areas. Specifically, each processing area includes a separate motor driven conveyor, sensors for providing information on conditions within the processing area, and a control circuit coupled to both the sensors and an operator interface.

A user may manipulate the operator interface to monitor sensed conditions within each processing area. Although the reference suggests an aspect of modularity that may offer certain limited benefits, it does not contemplate improvements to the overall process flow within the manufacturing chain. In fact, the reference does not disclose modifications to the exemplary high-speed blank powder
coating process, but rather seeks to quickly identify a source of a mechanical
problem associated with the process. As should be appreciated, there is a
continuing need for manufacturing chains providing improved quality and
efficiency with respect to a manufacturing process. In addition, there is a
continuing need for manufacturing chains, or manufacturing stations thereof, that
may be more easily modified, removed, or replaced.

The present disclosure is directed to one or more of the problems
set forth above.

**Summary of the Disclosure**

In one aspect, a material handling system includes a composite
beam including an upper rail and a lower track connected through a plurality of
spaced apart transverse members. A trolley includes an upper set of wheels and a
lower set of wheels. The lower set of wheels is received within two parallel
channels defined by the lower track. A drive tube is positioned between the
upper rail and the lower track such that the upper set of wheels are in frictional
engagement with the drive tube. A drive system is configured to rotate the drive
tube.

In another aspect, a method of operating a material handling
system includes a step of transporting a trolley having an upper set of wheels and
a lower set of wheels along the material handling system, at least in part, by
supporting the lower set of wheels of the trolley within two parallel channels
defined by a lower track. The upper set of wheels of the trolley is frictionally
engaged with a drive tube. The drive tube is rotated to move the lower set of
wheels within the two parallel channels. A weight carried by the trolley is
supported with a composite beam including an upper rail and the lower track
connected through a plurality of spaced apart transverse support members.

Detailed Description

An exemplary embodiment of a manufacturing chain 10 is shown generally in Figure 1. The manufacturing chain 10 may be disposed within a manufacturing area 12, such as, for example, a manufacturing area defined by a building 14. According to one embodiment, the manufacturing chain 10 may be secured to, and positioned above, a planar floor 16 of the manufacturing area 12. However, numerous locations and arrangements are contemplated for the manufacturing chain 10. According to the exemplary embodiment, the manufacturing chain 10 may be used to perform a paint process, such as, for example, a powder coating process, and, therefore, may also be referred to as a paint line. Although a paint process is described, however, it should be
appreciated that the manufacturing chain 10 may be designed to perform any of a variety of manufacturing processes.

The manufacturing chain 10, also referred to as a modular manufacturing chain, may include several modular manufacturing stations, such that each modular manufacturing station is configured to perform at least one task in the manufacturing process. Specifically, and according to one example, the manufacturing chain 10 may include a wash station 18, a blow off station 20, an inspection station 22, a paint application station 24, a curing station 26, and an unload station 28. Although six modular manufacturing stations 18, 20, 22, 24, 26, and 28 are shown, it should be appreciated that the manufacturing chain 10 may include any number of modular manufacturing stations necessary to perform the designated manufacturing process. It should also be appreciated that the paint process, as described herein, has been simplified for ease of explanation, and is in no way meant to be limited to the specific tasks described.

The modular manufacturing stations 18, 20, 22, 24, 26, and 28 may be positioned in series, as shown, or the manufacturing chain 10 may include one or more of the modular manufacturing stations 18, 20, 22, 24, 26, and 28 positioned in parallel, as dictated by the specific tasks of the manufacturing process. Further, the modular manufacturing stations 18, 20, 22, 24, 26, and 28 may include equipment, and other components, necessary to accomplish the task to be performed at the respective one of the modular manufacturing stations 18, 20, 22, 24, 26, and 28. It should be appreciated that multiple tasks may be performed at one modular manufacturing station or, alternatively, a more complex task may be performed over a plurality of modular manufacturing stations. Ultimately, one or more tasks may be performed on an article, or product, as it is transported through the modular manufacturing stations 18, 20, 22, 24, 26, and 28 along an article transportation system 30, described later in greater detail.
The equipment and other components necessary to perform a task at a respective one of each of the modular manufacturing stations 18, 20, 22, 24, 26, and 28 may be supported by a framework or, more specifically, a manufacturing module 32. For example, the manufacturing chain 10 may include a plurality of manufacturing modules 32 positioned and configured to accommodate the modular manufacturing stations 18, 20, 22, 24, 26, and 28. As shown in the embodiment of Figure 1, the manufacturing modules 32 may be positioned in series, as dictated by the modular manufacturing stations 18, 20, 22, 24, 26, and 28. However, the size and geometry of the manufacturing chain 10, comprising the manufacturing modules 32, may include any of a variety of possible sizes and configurations, such as, for example, an "L" shaped configuration or a "U" shaped configuration. Further, although Figure 1 illustrates exactly one of the modular manufacturing stations 18, 20, 22, 24, 26, and 28 associated with each manufacturing module 32, it should be appreciated that each manufacturing module 32 may support more than one of the modular manufacturing stations 18, 20, 22, 24, 26, and 28.

According to the exemplary embodiment, the wash station 18 may be configured to perform a wash and/or rinse task of the paint process. Specifically, the wash station 18 may include a water tank 34, supported by the manufacturing module 32, for supplying water, or a solvent mixture, to the wash station 18. Alternatively, however, water may be supplied directly to the wash station 18 from a utility infrastructure of the building 14 or, alternatively, from an external utility connection 36 disposed outside the manufacturing area 12 and connected to the manufacturing chain 10 via a conduit 38. The external utility connection 36 may, therefore, include a source of water or, alternatively, may include a source of another utility, such as, for example, electric power or data.

According to the current embodiment, the conduit 38 may provide water to a utility transfer module 40 supported by the manufacturing module 32. The utility transfer module 40 may be configured to transfer a utility, such as, for example, water.
example, electric power, fluid, or data, through the manufacturing module 32. The utility may be used at the wash station 18 and, further, may be transferred to a contiguous manufacturing module 32. For example, each of the other manufacturing modules 32 may include utility transfer modules 40, such that a utility may be supplied at one manufacturing module 32 and used at another. Specifically, each manufacturing module 32 may receive a utility from a preceding manufacturing module 32 of the manufacturing chain 10, and may transfer the utility to a succeeding manufacturing module 32.

The wash station 18 may further include a water pump 42 for circulating the water or solvent mixture through the wash station 18 and/or pressurizing the water or solvent mixture. According to one embodiment, the water or solvent mixture may be directed through a plurality of water nozzles 44, such that the water nozzles 44 are configured to spray an article as it passes through the wash station 18 to remove any foreign substances deposited on the article. Such foreign substances may include, for example, grease, dirt, dust, oils, or any other substances that may interfere with the paint application process. The wash station 18 may also include a plurality of water barrier panels 46 for preventing the water or the solvent mixture from escaping the wash station 18, and a drain system for returning the used water or the solvent mixture to the water tank 34. It should be appreciated that the wash station 18 may include any equipment useful in removing foreign substances from an article before paint, such as, for example, powdered paint, is applied.

The blow off station 20 may be configured to remove any water or solvent mixture remaining on the article after the article passes through the wash station 18. Specifically, the blow off station 20 may include a fan 48, or pump, for pressurizing air and a plurality of air nozzles 50 for directing the pressurized air toward the article. Either or both of the fan 48 and air nozzles 50 may be supported by the manufacturing module 32. Further, the blow off station 20 may include a hose (not shown) available to an operator for manually directing
pressurized air toward the article. According to one embodiment, pressurized air may be provided via the utility transfer module 40. Specifically, pressurized air may be supplied to the utility transfer module 40 directly from a source, or indirectly via the utility transfer module 40 of a contiguous manufacturing module 32.

Air barrier panels 52, or walls, may also be provided at the blow off station 20 for preventing pressurized air blown from the air nozzles 50 from interfering with activities or equipment outside of the blow off station 20. After the water or solvent mixture is sufficiently removed from the article at the blow off station 20, the article may be transported to the inspection station 22, which may provide a location for an operator 54 to inspect the article. The inspection may, for example, involve visual, physical, or chemical analyses to determine the presence of any remaining impurities on the surface of the article.

After inspection, the article may be transported along the article transportation system 30 to the paint application station 24. The paint application station 24 may include a piece of paint application equipment 56 for coating the article with paint, such as, according to one example, a powdered paint. The paint application station 24 may further include a plurality of paint barrier panels 58 for restricting the paint to the confines of the paint application station 24.

Either or both of the paint application equipment 56 and the paint barrier panels 58 may be supported by the manufacturing module 32. Alternatively, however, the paint application equipment 56 and the paint barrier panels 58 may be secured to the planar floor 16. As should be appreciated, the equipment used at the paint application station 24 may vary, depending on the type of paint used and the application process that is implemented. For example, the paint may be sprayed onto the article or, alternatively, the article may be immersed in a tank containing paint.

From the paint application station 24, the article may be transported to the curing station 26. The curing station 26 may be configured to
heat or otherwise cure the coating of freshly applied paint. According to one embodiment, the curing station 26 may include a plurality of infrared heaters 60, which may contain a plurality of infrared heater lamps 62 for generating the heat necessary for causing the coating of paint on the article to cure. According to one embodiment, the infrared heaters 60 may be portable. For example, one or more sets of rollers 64 may be provided to facilitate movement of the infrared heaters 60 from one location, such as a storage location, and into the illustrated position relative to the paint application station 24. It should be appreciated that "portable" equipment, as used herein, may refer to any equipment or component that may not be characterized as a fixture or otherwise permanently attached component. It should also be appreciated that any equipment useful in making the coating of paint applied to the article permanent is contemplated for use at the curing station 26.

For simplicity, the exemplary paint process is described as having one paint application station 24; however, it should be appreciated that a paint process may often include coating the article with multiple coatings of paint. As a result, the manufacturing chain 10 may include additional paint applications stations 24 and, if necessary, manufacturing modules 32 to accommodate such a process. Ultimately, after the desired number of paint coatings are applied to the article, the article may be transported to the unload station 28. At the unload station 28, the article may be removed from the manufacturing chain 10 or, more specifically, the article transportation system 30 by an operator 66. After passing through the manufacturing chain 10, it is contemplated that the article may be transported to another manufacturing chain for further processing, if desired. According to one embodiment, the article may be routed to a buffer area before passing to another manufacturing chain. Alternatively, the article may be taken to a storage location for storage, or to a transportation vehicle for delivery to a customer.
Turning now to Figure 2, an exemplary manufacturing module 32 for supporting one or more of the modular manufacturing stations 18, 20, 22, 24, 26, and 28 of Figure 1 is shown in greater detail. Specifically, the manufacturing module 32 may consist of a plurality of beams, such as tubular beams, forming a framework or skeleton 80. According to one embodiment, the skeleton 80 may include a plurality of vertically aligned support beams 82, 84, 86, and 88 attached to the planar floor 16 using support plates 90, 92, 94, and 96, respectively. Although a bolted connection is shown, it should be appreciated that the support beams 82, 84, 86, and 88 and/or support plates 90, 92, 94, and 96 may be attached to the planar floor 16 using any secure connection.

The vertically aligned support beams 82, 84, 86, and 88 may be interconnected using a plurality of additional support beams, such as horizontally aligned beams 98, 100, 102, and 104. The horizontally aligned support beams 98, 100, 102, and 104 and vertically aligned support beams 82, 84, 86, and 88 may define an entry 106 and an exit 108 of the manufacturing module 32, and may provide structural support for one or more modular manufacturing stations, such as the modular manufacturing stations 18, 20, 22, 24, 26, and 28 of Figure 1. As such, the support beams 82, 84, 86, 88, 98, 100, 102, and 104 may be fabricated from steel, carbon composites, or any other material known in the art suitable for providing the desired support. According to one embodiment, it may be desirable to utilize a relatively lightweight material to ease the transport and/or construction of the manufacturing module 32.

Additionally, it may be desirable to allow for expansion and/or contraction of one or more of the support beams 82, 84, 86, 88, 98, 100, 102, and 104. Such expansion and/or contraction may further ease the transport and/or construction of the manufacturing module 32, and may also allow for a customized size and/or shape of each manufacturing module 32. For example, the desired size and/or shape of the manufacturing module 32 may depend upon a number of factors including, but not limited to, the number of modular
manufacturing stations, such as modular manufacturing stations 18, 20, 22, 24, 26, and 28, disposed within the manufacturing module 32.

To facilitate adjustment, one or more of the support beams 82, 84, 86, 88, 98, 100, 102, and 104 may include a hollow tubular portion and a piston portion. For example, vertically aligned support beam 82 is shown having a tubular portion 82a and a piston portion 82b. As should be appreciated, the piston portion 82b may be slidably received within the tubular portion 82a and locked at a desired length. Locking may be accomplished using any known fastening devices, such as, for example, bolts, screw, pins, or spring-actuated bearings. Alternatively, however, each of the support beams 82, 84, 86, 88, 98, 100, 102, and 104 may be fabricated to various desired lengths, as dictated by the design of the manufacturing module 32. According to one embodiment, it may be desirable to expand and/or contract only the vertically aligned support beams 82, 84, 86, and 88.

Although the support beams 82, 84, 86, 88, 98, 100, 102, and 104 are illustrated as forming a cubic shape, they may, alternatively, be positioned to form any shape conducive to the specific manufacturing process being performed. Additionally, the number of support beams 82, 84, 86, 88, 98, 100, 102, and 104 utilized to form the skeleton 80 may vary depending upon the shape of the manufacturing module 32. The support beams 82, 84, 86, 88, 98, 100, 102, and 104 of the manufacturing module 32 may be secured together by mechanical fasteners, welds, or any other devices known in the art that are used to secure components. Additionally, the skeleton 80 of the manufacturing module 32 may be attached to the framework of a contiguous manufacturing module 32 using similar fasteners. Alternatively, however, the manufacturing module 32 may be positioned adjacent a contiguous manufacturing module 32 and may not be attached thereto. A "contiguous" manufacturing module, as used herein, may refer to a manufacturing module, such as manufacturing module 32, positioned in
close proximity to another manufacturing module, such as, for example, a preceding or succeeding manufacturing module in the manufacturing chain 10.

One or more of the support beams 82, 84, 86, 88, 98, 100, 102, and 104 of the skeleton 80 may support the utility transfer module 40. The utility transfer module 40 may be configured to transfer at least one of electric power, fluid, and data through the manufacturing module 32. Specifically, the utility transfer module 40 may transfer and/or provide electric power, water, compressed air, gas, or other utilities to the one or more modular manufacturing stations, such as modular manufacturing stations 18, 20, 22, 24, 26, and 28, supported by the manufacturing module 32. According to one embodiment the utility transfer module 40 may include a collection of wires, cables, or other conduits capable of transferring one or more utilities.

The utility transfer module 40 may include an external port 110 for engaging an external utility connection, such as, for example, the external utility connection 36 of Figure 1. Although the external utility connection 36 is positioned outside the building 14, it should be appreciated that the external utility connection 36 may be positioned within the building 14, such as within the manufacturing area 12. Accordingly, each utility transfer module 40 may include multiple external ports 110, depending on the number of utility sources to be engaged.

Each utility transfer module 40 may also include an entry port 112 for engaging a utility transfer module 40 of a preceding manufacturing module 32, and an exit port 114 for engaging a utility transfer module 40 of a succeeding manufacturing module 32. It should be appreciated that the entry port 112 of the utility transfer module 40 of the first manufacturing module 32 in the
manufacturing chain 10 may remain unused and, similarly, the exit port 114 of utility transfer module 40 of the last manufacturing module 32 may remain unused. Such ports, however, may become necessary, such as, for example, when an additional manufacturing module 32 is added to the manufacturing chain 10.

Additionally, the utility transfer module 40 may include one or more equipment ports, such as a first equipment port 116, for providing a utility to the one or more modular manufacturing stations, such as the modular manufacturing stations 18, 20, 22, 24, 26, and 28, of the manufacturing module 32. According to a more general example, manufacturing module 32 may support a first modular manufacturing station 118 that is configured to perform at least one task of a manufacturing process. Accordingly, the first modular manufacturing station 118 may include equipment, and other systems and/or components, necessary to accomplish the task to be performed. Specifically, and according to one example, the first modular manufacturing station 118 may include a piece of manufacturing equipment 120, an article transportation device 122 representing a portion of the article transportation system 30 corresponding to the station 118, and a station control system 124. Although the manufacturing equipment 120 is exemplified as a plurality of air nozzles, similar to air nozzles 50, it should be appreciated that any manufacturing equipment useful in performing a manufacturing task is contemplated.

One or more of the manufacturing equipment 120, the article transportation device 122, and the station control system 124 may receive utilities, such as electric power, fluid, and data, from the utility transfer module 40. For example, the manufacturing equipment 120 may include a conduit 126 having a quick connect coupling member 128 for engaging the first equipment port 116. Similarly, the article transportation device 122 may include a conduit 130 having a quick connect coupling member 132 for engaging a second equipment port 134 of the utility transfer module 40. In addition, the station
control system 124 may include conduit 136 having a quick connect coupling member 138 for engaging a third equipment port 140 of the utility transfer module 40.

It should be appreciated that any of the ports or connections described herein, such as, for example, ports 110, 112, 114, 116, 134, and 140, may embody electrical outlets, quick connect coupling members, or any other known utility interfaces. In addition, each of the quick connect coupling members 128, 132, and 138 may embody any appropriate utility interface for engaging one or more of the ports 110, 112, 114, 116, 134, and 140. It should also be appreciated that quick connect coupling members may enable relatively quick and easy assembly and/or disassembly of the manufacturing stations, such as modular manufacturing stations 18, 20, 22, 24, 26, and 28, and/or first modular manufacturing station 118. Additional benefits may be recognized by utilizing common, or universal, interfaces throughout the entire manufacturing chain 10.

According to one embodiment, the utility transfer module 40 may be secured to one of the support beams 82, 84, 86, 88, 98, 100, 102, and 104, such as support beam 102, using one or more mounting devices 142. Mounting devices 142 may, for example, include hooks, latches, sockets, or any other devices capable of securing the utility transfer module 40 to one or more of the support beams 82, 84, 86, 88, 98, 100, 102, and 104. Alternatively, however, the utility transfer module 40 may be positioned within a hollow portion, such as, for example, a central portion, of one or more of the tubular support beams 82, 84, 86, 88, 98, 100, 102, and 104. It should be appreciated that the utility transfer module 40 may be supported by and/or secured to any number of the support beams 82, 84, 86, 88, 98, 100, 102, and 104, as necessary to transfer a utility through and/or provide a utility to the manufacturing module 32.

Turning now to Figure 3, an alternative embodiment of a manufacturing module 32 is shown. Specifically, one or more of the manufacturing modules 32 may include a second modular manufacturing station
160 disposed between the entry 106 and the exit 108 of the manufacturing 
module 32. The second modular manufacturing station 160 may include similar 
systems and/or components as the first modular manufacturing station 118. 
Specifically, the second modular manufacturing station 160 may include at least 
one piece of manufacturing equipment 120, an article transportation device 122 
representing a portion of article transportation system 30 corresponding to the 
second modular manufacturing station 160, and a station control system 124. 

It should be appreciated that each of the systems and/or 
components of the second modular manufacturing station 160 may also receive a 
utility from the utility transfer module 40 in a manner similar to that described 
above. It should further be appreciated that either or both of the first and second 
modular manufacturing stations 118 and 160 may be representative of the 
modular manufacturing stations 18, 20, 22, 24, 26, and 28 of Figure 1. 
Accordingly, each of the modular manufacturing stations 18, 20, 22, 24, 26, and 
28 may generally include one or more of the manufacturing equipment 120, 
article transportation device 122, and station control system 124. 

Each article transportation device 122 may include a friction drive 
system having one or more sets of carrier tracks, such as carrier tracks 162, along 
which a carrier 164 may be transported. It should be appreciated that the one or 
more sets of carrier tracks 162 may define a transportation path 166 through a 
manufacturing chain, such as the manufacturing chain 10 of Figure 1. Friction 
drive systems are known, and may generally include one or more hanger rails 168 
fixedly attached to the skeleton 80 for supporting one or more support rails 170. 
At least one of the support rails 170 may provide support for a drive shaft 172 
that may be mechanically coupled to a drive system 174. 

The drive system 174 may, for example, include an electric, 
hydraulic, or pneumatic motor, and may further include a transmission and 
controls, as necessary, for driving the drive shaft 172 at a desired speed and in a 
desired direction. For example, the drive shaft 172 may be rotated in a first
direction for frictionally engaging wheels of the carrier 164 such that the carrier 164 is moved in a forward transport direction, represented by arrow "F". Alternatively, however, the drive shaft 172 may be rotated, by the drive system 174, in an opposite direction for frictionally engaging wheels of the carrier 164 to move the carrier 164 in a reverse transport direction "R" that is opposite the forward transport direction "F." A similar friction drive system may be provided by OCS IntelliTrak, Incorporated of Cincinnati, Ohio.

Although a friction drive system is described, however, it should be appreciated that a variety of material handling systems may be used. For example, an air balancer, a series of hoists, an electrified monorail, or any other device capable of moving an article through the manufacturing chain 10 are also contemplated. Further, it should be appreciated that carriers, such as carriers 164, may include any devices capable of gripping an article to be conveyed through the manufacturing chain 10. Exemplary carriers may, for example, include hooks, clamps, latches, or any other devices capable of temporarily grasping the article. Although a single carrier 164 is depicted for transporting an article, it should be appreciated that multiple carriers may be necessary for transporting the article, depending on the size and weight of the article.

It is also contemplated that the article transportation system 30 may be substituted with a chain, belt, or any other device that may convey carriers 164 through the manufacturing chain 10. According to one embodiment, the article transportation system 30 may be mounted to the planar floor 16 and/or contain a transport device, such as, for example, a conveyor belt to convey the article through the manufacturing chain 10. Preferably, however, the article transportation devices 122 that define the article transportation system 30 may each include at least one drive system 174, or similar means, for facilitating independent movement of the carrier 164 within the respective one of the manufacturing stations 118 and 160.
Each station control system 124 may be configured to control operation of at least one of the article transportation device 122 and the manufacturing equipment 120 of the respective one of the modular manufacturing stations 118 and 160. Specifically, the station control system 124 may be in communication with the article transportation device 122 or, more specifically, the drive system 174, and may be configured to issue an operation signal, such as, for example, a forward signal, a reverse signal, and a stop signal. The forward signal may correspond to the forward transport direction "F," the reverse signal may correspond to the reverse transport direction "R," and the stop signal may correspond to a stationary position. It should be appreciated that the stationary position may represent a state in which the carrier 164 is not driven in either of the forward transport direction "F" or the reverse transport direction "R".

According to one embodiment, the carrier 164 of the first modular manufacturing station 118 may be driven in the forward transport direction "F" while the carrier 164 of the second modular manufacturing station 160 is simultaneously driven in the reverse transport direction "R" or, alternatively, remains stationary. According to a specific example, it may be desirable to move the carrier 164 of the second modular manufacturing station 160 in the reverse transport direction "R" relative to the manufacturing equipment 120. As should be appreciated, continuous forward and reverse movement relative to the manufacturing equipment 120 may prove beneficial in a variety of tasks of a manufacturing process, including, but not limited to, a wash task and a blow off task, as described above. According to an additional example, it may be desirable to stop the carrier 164 of the second modular manufacturing station 160, such as in response to the identification of a defect, while one or more other carriers 164 continue to move. A variety of defects are contemplated, such as, for example, defects resulting from process problems and/or equipment failures.

Each modular manufacturing station 118 and 160 may also include one or more position tracking devices. According to one embodiment, a first
position tracking device 176, a second position tracking device 178, and a third position tracking device 180 are each positioned for detecting a position of the carrier 164 as it is transported through the station 118 and 160. Position tracking devices 176, 178, and 180 are known, and may include, for example, position sensors, proximity switches, bar code readers, or any other devices capable of detecting a position of the carrier 164. In addition, the position tracking devices 176, 178, and 180 may be supported by the skeleton 80, the article transportation device 122, or may be otherwise positioned. Although three position tracking devices 176, 178, and 180 are shown, it should be appreciated that any number of position tracking devices may be used, as dictated by the manufacturing process.

Each station control system 124 may also be in communication with the position tracking devices 176, 178, and 180, and may receive signals from one or more of the position tracking devices 176, 178, and 180 that are indicative of first, second, and third detected positions of the carrier 164. Each station control system 124 may also be configured to issue one or more operation signals, such as, for example, the forward signal, reverse signal, and stop signal, to the article transportation device 122 based, at least in part, on one of the detected carrier positions. According to one example, it may be desirable for the station control system 124 to issue the stop signal to the article transportation device 122 when the carrier 164 has reached a predetermined position relative to the manufacturing equipment 120. After a predetermined period of time, for example, the station control system 124 may then issue the forward signal to the article transportation device 122. Further, the station control system 124 may issue one or more operation signals to the manufacturing equipment 120 based, at least in part, on one of the detected carrier positions.

Turning now to Figure 4, an alternative embodiment of a manufacturing module 32 is shown. Specifically, the transportation path 166 defined by the carrier tracks 162 may include a vertical discontinuity 200. It should be appreciated that, according to one example, the vertical discontinuity
200 may occur where the transportation path 166 includes a first transport height 202 that is vertically spaced from a second transport height 204. Specifically, the two sets of carrier tracks 162 of the first modular manufacturing station 118 may be positioned at the first transport height 202, while the carrier tracks 162 of the second modular manufacturing station 160 are positioned at the second transport height 204. Such a discontinuity along the transportation path 166 may occur as a result of the design of the manufacturing chain 10, as dictated by a topography of the manufacturing area 12 or a variety of other factors. Additionally, it may be desirable to alter the height of the transportation path 166 relative to the manufacturing equipment 120.

A first vertical lift device 206 may be provided for moving one of the sets of carrier tracks 162 in a vertical direction relative to the transportation path 166. Specifically, the first vertical lift device 206 may be configured to move one of the sets of carrier tracks 162, adjacent the vertical discontinuity 200, from the first transport height 202 to the second transport height 204. Vertical lift devices, such as vertical lift device 206, are known, and may include, for example, electric or pneumatic lifts, and, as such, may receive any necessary utilities from the utility transfer module 40. In addition, the first vertical lift device 206 may be supported by and/or secured to the skeleton 80 of the manufacturing module 32.

A control system, such as, for example, the station control system 124, may also be provided for controlling operation of the first vertical lift device 206. Specifically, and according to one embodiment, the station control system 124 may also be in communication with the first vertical lift device 206, and may be configured to issue operation signals thereto, such as, for example, a raise signal and a lower signal. For example, the first vertical lift device 206 may be configured to move the carrier tracks 162 from the first transport height 202 to the second transport height 204 in response to the raise signal. In addition, the first vertical lift device 206 may be configured to move the carrier tracks 162
from the second transport height 204 to the first transport height 202 in response to the lower signal.

Further, the station control system 124 may be configured to issue the raise signal and/or the lower signal in response to a carrier position that is detected by one of the position tracking devices 176, 178, and 180. Specifically, and according to one example, it may be desirable to issue the raise signal when it is determined that the carrier 164 has reached a predetermined position relative to the carrier tracks 162. After the carrier tracks 162 have been raised, the carrier 164 may continue to be transported along the transportation path 168 at the second transport height 204, such as by the drive system 174.

The transportation path 168 may include additional vertical discontinuities, such as, for example, a second vertical discontinuity 210, shown in Figure 5. A second vertical lift device 212, similar to first vertical lift device 206, may, therefore, be provided to advance the carrier 164 through the second vertical discontinuity 210. Specifically, the second vertical lift device 212 may move the carrier tracks 162 from the second transport height 204 to the first transport height 202, such as in response to the lower signal issued from the station control system 124. It should be appreciated that the station control system 124 may issue the lower signal in response to a carrier position detected by one of the position tracking devices 176, 178, and 180. It should also be appreciated that any number of vertical lift devices, such as lift devices 206 and 212 that may be manually or automatically operated, may be used throughout the manufacturing chain 10 to accommodate vertical discontinuities and/or to move one of the carriers 164 in a vertical direction relative to the manufacturing equipment 120.

According to one embodiment, it may be desirable to incorporate one or more vertical lift devices, such as the lift devices 206 and 212, into the manufacturing chain 10 to accommodate manufacturing equipment 120 positioned above the planar floor 16. Specifically, the manufacturing chain 10
may include one or more pieces of manufacturing equipment 120 that
traditionally were positioned below the planar floor 16, such as, for example,
tanks or baths. For ease of deployment, the manufacturing chain 10 may position
all equipment 120, including such tanks or baths, above ground and, therefore,
may advance the carriers 164 through the manufacturing chain 10 and relative to
the manufacturing equipment 120 using one or more vertical lift devices 206 and
212.

It should be appreciated that utilizing an article transportation
device 122 having at least one of reverse, stop, and lift capabilities may allow a
decrease in size and/or output capacity of the manufacturing equipment 120. For
example, a conventional curing station may require a relatively large infrared
heater capable of generating a large amount of heat. Specifically, the infrared
heater may be sized to adequately cure a coating of paint on an article as it passes
through the curing station at a speed equal to an overall line speed. However, the
article transportation device 120, as described herein, may stop and/or reverse the
article as it passes through the curing station 26. Therefore, the manufacturing
equipment 120 or, more specifically, the infrared heaters used therein may have a
lower heat output requirement. As a result, significant cost savings relative to the
manufacturing equipment 120 may be recognized.

An exemplary control system 220 for the manufacturing chain 10
is shown generally in Figure 6. Specifically, the control system 220 may include
the station control systems 124 of each modular manufacturing station within the
manufacturing chain 10, such as the modular manufacturing stations 18, 20, 22,
24, 26, and 28. It should be appreciated that the modular manufacturing stations
18, 20, 22, 24, 26, and 28 of Figure 1 may include configurations similar to any
of the embodiments of the first and second modular manufacturing stations 118
and 160 of Figures 2-5. Specifically, the manufacturing modules 32 of the
manufacturing chain 10, as shown in Figure 1, may each include one or more of
the modular manufacturing stations 18, 20, 22, 24, 26, and 28, as dictated by the manufacturing process to be performed.

The station control systems 124 may include any commercially available microprocessors that include means for controlling the operation of at least one of the article transportation device 122 and the manufacturing equipment 120 of the respective manufacturing stations 18, 20, 22, 24, 26, and 28. Generally, each station control system 124 may include a processor 222, a memory 224, and any other components for running an application. Various circuits may also be associated with the station control systems 124, such as utility supply circuitry, signal conditioning circuitry, and any other types of circuitry needed for the operation of the respective manufacturing stations 18, 20, 22, 24, 26, and 28.

The station control systems 124 may each receive input from an operator interface 226, and may control and/or override the operation of the article transportation device 122 and/or manufacturing equipment 120 of the respective manufacturing stations 18, 20, 22, 24, 26, and 28 in response to the input. As should be appreciated, the operator interface 226 may receive an operator input command that is indicative of a desired operation. Accordingly, the operator interface 226 may include a touch screen, keyboard, control panel, or any other device or mechanism capable of facilitating communication between the operator and the station control systems 124. It is also contemplated that the input could alternatively be a computer-generated command from an automated system that assists the operator, or an autonomous system that operates in place of the operator.

According to one embodiment, the memory 224 of each station control system 124 may include a unique operation pattern corresponding to a specific task stored thereon. For example, the unique operation pattern may include one or more operation signals to be transmitted to at least one of the article transportation device 122 and the manufacturing equipment 120 via at
least one communications conduit 228. Such operation signals may, for example, include the forward signal, the reverse signal, and the stop signal, as described above. In addition, the raise signal and the lower signal may be issued to an article transportation device 122 that includes a vertical lift device, such as vertical lift devices 206 and 212. Further, operation signals, such as, for example, a begin operation signal and a stop operation signal that may, intuitively, start or stop operation of the manufacturing equipment 120, may also be issued. It should be appreciated that a "unique operation pattern," as used herein, may generally refer to any sequence or pattern of movements or operations that facilitate the performance of a task, including such parameters as speed and direction of travel.

Each of the station control systems 124 may issue an operation signal, as describe above, in response to an operator input or, alternatively, automatically and according to a predetermined pattern, such as corresponding to the unique operation pattern stored thereon. According to one embodiment, the station control systems 124 may be in communication with the position tracking devices 176, 178, and 180 via the communications conduit 228, and may be configured to receive signals indicative of detected carrier positions. The station control systems 124 may also be configured to issue at least one of the operation signals corresponding to the unique operation pattern, based, at least in part, on one or more of the detected carrier positions.

A main control system 230 may be provided for coordinating operation of the station control systems 124 of each modular manufacturing station 18, 20, 22, 24, 26, and 28. Alternatively, however, one of the station control systems 124 may be designated a master control system for coordinating operation of the manufacturing chain 10. The main control system 230 may be of standard design and may generally include a processor 232, such as, for example, a central processing unit, a memory 234, and an input/output circuit, such as the communications conduit 228. It should be appreciated that the communications
conduit 228, as referenced herein, may represent any form of wired and/or wireless communications, and may generally represent the transmission of any of the operation signals and/or positions signals described above. According to one embodiment, one or more data communications may be transmitted via the utility transfer modules 40.

The processor 232 may control operation of the main control system 230 by executing operating instructions, such as, for example, programming code stored in the memory 234, wherein operations may be initiated internally or externally to the main control system 230. As should be appreciated, a control scheme may be utilized that monitors outputs of the systems and/or components of each modular manufacturing station 18, 20, 22, 24, 26, and 28, such as, for example, sensors, actuators, or control units, via the communications conduit 228. Such information may, for example, be used to control inputs to the station control systems 124 and/or other systems and components of the each of the modular manufacturing stations 18, 20, 22, 24, 26, and 28.

According to one example, the memory 234 of the main control system 230 may store a plurality of unique operation patterns thereon. The main control system 230 may receive signals indicative of the first, second, and third detected carrier positions from each of the station control systems 124. In response, the main control system 230 may independently transmit operation signals, such as operation signals corresponding to one of the unique operation patterns, to each of the station control systems 124. The station control systems 124 may, in turn, transmit the operation signals to the article transportation device 122 and/or the manufacturing equipment 120 at the respective stations 18, 20, 22, 24, 26, and 28.

The main control system 230 may also index the carriers 164 of each modular manufacturing station 18, 20, 22, 24, 26, and 28 as each carrier 164 traverses to a contiguous station 18, 20, 22, 24, 26, and 28. According to one
embodiment, the main control system 230 may simultaneously issue an index
signal to the station control systems 124 of each modular manufacturing station
18, 20, 22, 24, 26, and 28. As such, the processors 222 of each station control
system 124 may be configured to await and/or anticipate the index signal from
the main control system 230 after the task to be performed at the respective
station has been completed.

According to one example, indexing may include detecting a
desired position of the carrier 164 within each station 18, 20, 22, 24, 26, and 28,
such as by using one or more of the position tracking devices 176, 178, and 180.
The main control system 230 may be configured to await signals from each
modular manufacturing station 18, 20, 22, 24, 26, and 28 that are indicative of the
desired position and then simultaneously transfer each carrier 164 to a contiguous
station 18, 20, 22, 24, 26, and 28. Additional operation signals, therefore, may
also be useful for indexing, such as, for example, the stop signal, a speed adjust
signal, a transfer signal, or any other signal useful for detecting and transferring
the carriers 164.

By coordinating operation of the entire manufacturing chain 10,
the main control system 230 may receive a carrier position signal from one
modular manufacturing stations based, at least in part, on that carrier position signal. For
example, it may be desirable to transfer the carrier 164 of modular manufacturing
station 18 only when the carrier 164 of the modular manufacturing station 20 has
reached a predetermined position, such as a position detected by one or more of
the position tracking devices 176, 178, and 180. It should be appreciated that the
main control system 230 may utilize position signals from all of the position
tracking devices 176, 178, and 180, at least in part, to coordinate operation of the
entire manufacturing chain 10.

The main control system 230 may also include an operator
interface, such as an interactive operator display 236, for continuously
monitoring and/or controlling operation of each modular manufacturing station 18, 20, 22, 24, 26, and 28 of the manufacturing chain 10. According to one embodiment, the interactive operator display 236 may be used to continuously monitor a status of each article transportation device 122 of the manufacturing chain 10. Further, the interactive operator display 236 may be configured to display a real-time visual representation of each carrier 164 being transported through the manufacturing chain 10. The interactive operator display 236 may also be configured to receive an operator input command from an operator and transmit the operator input command to the article transportation device 122 or the manufacturing equipment 120 of at least one of the modular manufacturing stations 18, 20, 22, 24, 26, and 28.

It should be appreciated that numerous applications and configurations of the control system 220 are contemplated. According to one embodiment, the main control system 230, station control systems 124, position tracking devices 176, 178, and 180, article transportation devices 122 and manufacturing equipment 120 may all be interconnected through a local area network, as shown in Figure 7. As such, the main control system 230 may directly communicate with the systems and/or components of each modular manufacturing station 18, 20, 22, 24, 26, and 28, and, therefore, may not direct communications, including operation signals, through the station control systems 124. Similarly, position signals may be communicated directly from the position tracking devices 176, 178, and 180 to the main control system 230.

An exemplary embodiment of a material handling system for use with the modular manufacturing chain 10, or modular manufacturing line, described herein is shown generally at 250. The material handling system 250, only a portion of which is shown, may include a composite beam 252 having an upper rail 254 and a lower track 256 connected through a plurality of spaced apart transverse members 258. As shown later in greater detail, the lower track 256 may define two parallel channels 260. A trolley 262, several of which are shown,
may include a lower set of wheels 264 that may be received within the two parallel channels 260 of the lower track 256. The lower track 256, along which the trolley 262 is movable, may define a rail of any standard size, including, for example, a 3”, 4”, or 6” rail. An upper set of wheels 266 of the trolley 262 may be in frictional engagement with a drive tube 268 of a friction drive system 270. The friction drive system 270, which may include a spinning tube friction drive system as provided by OCS IntelliTrak of Cincinnati, Ohio, may be similar to an exemplary embodiment of the article transportation device 122 described above, and may generally include a plurality of drive tubes 268 supported along the material handling system 250 and positioned in series to define a path through the modular manufacturing chain 10 (Figure 1). Each of the plurality of drive tubes 268 may be independently driven, or rotated, by one of a plurality of motors, such as electric drive motor 272. Therefore, depending on the number and length of independently driven drive tubes 268, the material handling system 250, or modular material handling system 250, may be customized to independently control each article as it is transported through the manufacturing chain 10.

As shown in the illustrated embodiment, a first trolley assembly 274 may be configured to support a first load bar 276. Specifically, a first end 278 of the first load bar 276 may be pivotably supported from a first trolley 280, while a second end 282 of the first load bar 276 may be pivotably supported from a second trolley 284. Similarly, second trolley assembly 285 may be configured to support a second load bar 286. More specifically, a first end 288 of the second load bar 286 may be pivotably supported from a third trolley 290, and a second end 292 of the second load bar 286 may be pivotably supported from a fourth trolley 294. A carrier 296, which may include any devices capable of gripping an article to be conveyed along the modular material handling system 250, may have a first end 298 pivotably supported from the first load bar 276 and a second end 300 pivotably supported from the second load bar 286. While a carrier, such as carrier 296, may be configured to support an article, load bars, such as first and
second load bars 276 and 286, may be configured to evenly distribute weight
carried by the carrier 296 among a plurality of trolleys 262. One skilled in the art
should appreciate that a trolley assembly, such as first trolley assembly 274 and
second trolley assembly 285, may include any number of trolleys 262 configured
to directly or indirectly support a carrier, such as carrier 296. Further, a load bar
assembly, such as the illustrated load bar assembly 302, may include any number
of trolleys 262 or trolley assemblies 274 and 285 supporting any number of load
bars 276 and 286. Such arrangements may be customized based on the weight to
be supported by the carrier 296.

According to another arrangement, one or more of the trolleys 262
may include a coupling mechanism for attaching the trolley 262 to another trolley
262. For example, the front of one trolley 262 may include coupling means
configured to attach to complementary coupling means provided on the back of
another trolley 262. Alternatively, similar coupling means may be provided to
attach carriers, such as carrier 296, or load bars, such as load bars 276 or 286.
Any such arrangements may be similar, in purpose, to conventional couplings for
attaching train cars to one another for pulling the train cars in a train. As such,
one or more trolleys 262, or carriers 296, may be transported along the material
handling system 250 in a coupled configuration. Such a coupled configuration
may, for example, be useful when transporting similar articles or when
transporting different articles that may be later combined into an assembly or a
sub-assembly.

Although not depicted, it should be appreciated that a single

trolley 262, which may also be referenced as a trolley assembly, may be
configured to directly support a carrier, such as carrier 296. As such, the friction
drive system 270, and trolley 262, may be configured to ensure that at least one
of the wheels of the upper set of wheels 266 continuously engages one of the
drive tubes 268. Specifically, the wheels of the upper set of wheels 266 may
bridge any gaps, such as gap 304, between drive tubes 268 of the friction drive
system 270. For trolley assemblies, such as trolley assemblies 274 and 285, which may include one or more trolleys 262 connected through one or more load bars, such as load bar 276, and/or carriers, such as carrier 296, it may be important to ensure that at least one of the trolleys 262 continuously engages one of the plurality of drive tubes 268.

The trolleys 262, described herein, may be of standard design, requiring a lower set of wheels 264, movable along the lower track 256, and an upper set of wheels 266 that are configured to frictionally engage the plurality of drive tubes 268. Such trolleys 262, according to one embodiment, may be modified versions of conventional power and free conveyor trolleys, or other trolleys known to those skilled in the art. To incorporate such standard components, a drive adapter may be provided that attaches a standard trolley, having lower wheels that are movable within the lower track 256, to the upper set of wheels 266, described herein. The upper wheels 266, as should be appreciated, are configured to frictionally engage the plurality of drive tubes 268. By incorporating such conventional components, such as by slightly modifying standard trolleys as described herein, costs of implementing the material handling system 250 may be reduced.

Turning now to Figures 9a-9c, cross-sectional views of alternative embodiments of the composite beam 252 are shown. Specifically, the composite beam 252 of Figure 9a may include the upper rail 254 and lower track 256 connected through transverse members 258, as described above with reference to Figure 8. As shown, each of the transverse members 258 may have an inverted U-shaped cross-section defining a pair of free ends 320. Each of the free ends 320 may support one of channels 260, which may be generally C-shaped channels, of the lower track 256. The channels 260, according to one embodiment, may be welded, or otherwise permanently affixed, to each of the plurality of transverse members 258. Although alternative attachment methods are contemplated, welding may be preferred to provide increased structural
strength of the composite beam 252 and, further, may allow the transverse members 258 to be positioned at longer centers. The upper rail 254, as shown in Figure 9a, may, according to one embodiment, include a T-shaped cross-section defining a central web 322 and a transverse flange 324. The central web 322, which may extend the length of the composite beam 252, may be received, and permanently affixed, within a vertically aligned slot 326 of an upper portion 328 of each of the transverse members 258.

According to alternative embodiments, shown in Figures 9b and 9c, the upper rail 254 of the composite beam 252 may include a pair of oppositely oriented structural members 330. Each of the structural members 330 may include a vertically oriented web 332 that is secured to each of the transverse members 258. Turning specifically to Figure 9b, each of the structural members 330 may be in the form of an angle iron having the vertically oriented web 332 and a horizontally oriented flange 334. The horizontally oriented flange 334, along with the transverse flange 324 of the embodiment of Figure 9a, may be used to secure a position of the composite beam 252 along the modular manufacturing chain 10 (Figure 1), as described below in greater detail.

According to this embodiment, and alternative embodiments, the composite beam 252 may also include a horizontally aligned support plate 336 secured to each of the pair of free ends 320 of the transverse members 258 and/or the channels 260 of the lower track 256.

The structural members 330, according to the embodiment of Figure 9c, may include the vertically oriented webs 332, which may be attached to the transverse members 258, and the horizontally oriented flanges 334, which may be used to attach the composite beam 252 to another structure. In addition, the structural members 330, as shown in Figure 9c, may include horizontally oriented flanges 340 that may be fixedly attached to each of the plurality of transverse members 258. Also shown in the embodiment of Figure 9c, the composite beam 252 may include a cable tray 342 supported, or defined, by the
composite beam 252. Specifically, the cable tray 342 may extend a length of the composite beam 252 and may be received, and secured, within openings 344 defined by the transverse members 258. Alternatively, the cable tray 342 may not extend the length of the composite beam 252, but may be defined only by the openings 344 of the transverse members 258. The cable tray 342 may be provided to accommodate one or more cables or conduits provided along the manufacturing chain 10. For example, the cable tray 342 may accommodate the utility transfer module 40, described above, which may be configured to transfer a utility, such as, for example, electric power, fluid, or data, through the modular manufacturing chain 10 of Figure 1, or another similar chain or line.

The one or more composite beams 252 of the material handling system 250 may be provided in any desired length, and may include one or more straight and/or curved sections. According to one embodiment, the composite beams 252, which may be made from iron, steel, aluminum, plastics, composites, and/or any other desired materials, may be provided in specific lengths selected to ease assembly of the modular manufacturing chain 10 of Figure 1. Specifically, the composite beams 252 may be pre-fabricated, or pre-constructed, prior to delivery to the manufacturing area 12 (Figure 1). Further, each composite beam 252 may be shipped with a predetermined length of cable 356, an electric drive motor 272, and a variable-frequency drive 358 for operating the electric drive motor 272, each of which may be later repositioned. As shown in Figure 10, each composite beam 252 may, according to the exemplary embodiment, be provided in a length corresponding to a length of a manufacturing module 360. The manufacturing module 360, which may be similar to the manufacturing module 32 described above, may include, according to one embodiment, a pair of end frames 362 connected through one or more central beams that define a mid-frame 364. One or more composite beams 252 may be supported from the manufacturing module 32 by attaching, such as by bolting, a plurality of connecting clamps 366 to the composite beam 252 and one
or more of the mid-frame 364 and the end frames 362. Once at least one composite beam 252 is attached to the mid-frame 364 and/or end frames 362, according to the exemplary embodiment, the end frames 362 may be secured to floor supported beams (not shown). Specifically, end posts 368 may telescopically receive, or may be otherwise attached to, corresponding floor mounted beams (not shown) to form the manufacturing module 360.

Alternatively, rather than end posts 368, the end frames 362 may include floor mounted support structures having an inverted "V-shape" oriented parallel to the composite beam 252.

According to yet alternative embodiments, the one or more composite beams 252 may be supported directly by the building 14, such as through cables suspended from a ceiling of the building 14. According to one example, the material handling system 250 may include a combination of ceiling or structure supported composite beams 252 and floor supported composite beams 252. The ceiling supported composite beams 252, as should be appreciated, may provide additional clearance for accommodating equipment, such as manufacturing equipment. Yet alternatively, the one or more composite beams 252 may be inverted to provide an on-floor conveyor, rather than the overhead conveyor that has been described. As should be appreciated by those skilled in the art, such an on-floor conveyor may represent an inverted version of the material handling system 250 described herein, with articles and respective carriers positioned, or supported, above the composite beams 252.

As described above, a plurality of manufacturing modules 360 may be positioned, such as in series, to define one or more paths through the modular manufacturing chain 10 of Figure 1. The modular material handling system 250, including one or more composite beams 252 and the friction drive system 270, described above, may be supported along the one or more paths defined by the manufacturing modules 360. When supporting the material handling system 250, it is important to note that the composite beams 252 and
friction drive system 270 must be aligned to provide continuous paths, as necessary. It should be appreciated that the friction drive system 270, as referenced herein, may comprise a plurality of friction drive modules, each of which includes one of the plurality of drive tubes 268 and a corresponding electric drive motor 272. Therefore, friction drive system 270, as used herein, may refer generally to the drive system, or material handling system 250, used throughout the entire modular manufacturing chain 10 (Figure 1), or to a specific one or more of the modules, or segments, of the friction drive system 270.

According to one implementation of the material handling system 250, shown in Figure 11a, one or more manufacturing modules 360 of a manufacturing line, such as the manufacturing chain 10 of Figure 1, may include a dual track, or multiple track, assembly. Specifically, as shown in the simplified plan view of Figure 11a, the material handling system 250 may include a first track assembly 380 configured to transport a forward trolley assembly 382, including one or more trolleys 262, along a first path 384, and a second track assembly 386 configured to transport a trailing trolley assembly 388, including one or more trolleys 262, along a second path 390. Each track assembly 380 and 386 may include one or more composite beams 252 and a friction drive system 270, as described above. The composite beams 252 of the first and second track assemblies 380 and 386 may be positioned, and/or secured, adjacent one another, without substantial modification, and, as such, may define paths 384 and 390 through one or more modules 360 that are substantially parallel. Together, the parallel paths 384 and 390 may define a transportation path 392 along which the forward trolley assembly 382 and the trailing trolley assembly 388 are spaced.

A carrier 394, configured to support an article, may have a first end 396 pivotably supported by the forward trolley assembly 382 and a second end 398 pivotably supported by the trailing trolley assembly 388. According to a specific arrangement, shown in Figure 11b, the first end 396 of the carrier 394 may be supported by the forward trolley assembly 382 through a first load bar
assembly 410, while the second end 398 of the carrier 394 may be supported by the trailing trolley assembly 388 through a second load bar assembly 412. Such a multiple track assembly, including two or more track assemblies, may be used to support articles of a substantial weight, such as, according to some embodiments, up to about 80,000 pounds. According to such arrangements, it may be desirable for the modular material handling system 250 to include at least the first track assembly 380 and the second track assembly 386 throughout the entire manufacturing chain 10, or line. However, it may be desirable to provide the multiple track assembly in only one or more modules of the manufacturing chain 10, as will be described below. It should be appreciated that, in such multiple track arrangements, it may be desirable to utilize the friction drive system 270 described herein, which inherently allows slippage, to successfully navigate any curves along the transportation path 392. Specifically, for example, one of the forward trolley assembly 382 and the trailing trolley assembly 388 may travel a greater distance than the other around such curves.

According to another implementation, the manufacturing chain 10 may include one or more buffers, such as a buffer 430, as shown in Figure 12. Specifically, the buffer 430, which may also be referred to as a sequencing buffer, may include a first track assembly 432 sized to receive at least two trolley assemblies 434, and a second track assembly 436 that is also sized to receive and support at least two trolley assemblies 434. According to some implementations, it may be desirable to provide a third track assembly 438, similar to the first track assembly 432 and the second track assembly 436, or any number of additional track assemblies. Each of the first, second, and third track assemblies 432, 436, and 438 may be vertically spaced, as shown, or may be otherwise positioned, as described below.

Each of the track assemblies 432, 436, and 438 may include any number of manufacturing modules 360 positioned such that the material handling system 250 of each track assembly 432, 436, and 438, including one or more
composite beams 252 and a friction drive system 270, defines a continuous path
along the respective track assembly 432, 436, or 438. According to one
embodiment, each module 360 may include one drive tube 268 and a
corresponding electric drive motor 272 for transporting the trolley assemblies 434
along the first, second, and third track assemblies 432, 436, and 438 in a forward
or reverse direction. As shown, each trolley assembly 434 may include a pair of
trolleys 262 configured to support an article 440 using a carrier 442. It should be
appreciated, however, that any number of trolleys 262 may be configured to
directly or indirectly support the carrier 442.

The buffer 430, illustrated as a stackable buffer, may also include
a first movable track assembly 444 that may include the material handling system
250 described above. The first movable track assembly 444 may be supported by
a manufacturing module 360 and may be movable between a plurality of
positions. For example, the first movable track assembly 444 may have a first
position that defines a continuous path along the first movable track assembly
444 and the first track assembly 432. A "continuous path," as used herein, may
reference any path along which a trolley 262 may be continuously transported.
The first movable track assembly 444 may also include a second position
(shown) defining a continuous path along the first movable track assembly 444
and the second track assembly 436. Further, for embodiments having a third
track assembly 438, the first movable track assembly 444 may have a third
position defining a third continuous path along the first movable track assembly
444 and the third track assembly 438.

A first programmable hoist 446, or other similar transfer device,
may be configured to move the first movable track assembly 444 between the
first, second, and third positions described above. The first programmable hoist
446 may be of conventional design and, further, may be integrated with the
control system 220, described above. The first movable track assembly 444 may
be positioned at a first end 448 of the buffer 430, or at any other desired position.
along the buffer 430. Further, the buffer 430, according to the exemplary embodiment, may include a second movable track assembly 450 positioned at a second end 452 of the buffer 430. The second movable track assembly 450, similar to the first movable track assembly 444, may be movable using a second programmable hoist 454, or other similar transfer device. Specifically, the second movable track assembly 450 may be movable between a first position (shown) defining a continuous path along the second movable track assembly 450 and the first track assembly 432, a second position defining a continuous path along the second movable track assembly 450 and the second track assembly 436, and a third position defining a continuous path along the second movable track assembly 450 and the third track assembly 438.

It should be appreciated that the track assemblies 432, 436, and 438 of the buffer 430 may, according to one alternative embodiment, be horizontally spaced, rather than vertically spaced. According to such implementations, the buffer 430 may utilize one or more lateral shuttles, described below, rather than programmable hoists 446 and 454, to move the movable track assemblies 444 and 450 into alignment with one of the first, second, and third track assemblies 432, 436, and 438. Such design choices, for example, may be based on spatial constraints of the manufacturing area 12 (Figure 1) and/or specific needs of the manufacturing processes that are supported. As such, the buffer 430 may include any number of stationary track assemblies, such as track assemblies 432, 436, and 438, having any desired capacity, positioned and/or stacked according to a customized configuration. Further, the buffer 430 may include any number of movable track assemblies, such as movable track assemblies 444 and 450, positioned at any useful positions throughout the buffer 430. Such a customized buffer 430 may be used to transport, store, sequence, and/or re-sequence carriers 442 and/or articles 440 supported thereon, as described below in greater detail.
During an exemplary operation, one or more of the trolley assemblies 434 may be distributed among the first track assembly 432 and the second track assembly 436 of the buffer 430 such that a first trolley assembly 456 is blocked from an exit position 458. The exit position 458 may represent a position within the buffer 430 from which a trolley assembly 434 may be removed from the buffer 430 without having to move another trolley assembly 434. For example, the exit position 458 may include a position that accommodates a continuous path onto a main path of a manufacturing line. To move the first trolley assembly 456 to the exit position 458, the plurality of trolley assemblies 434 may be redistributed among the first track assembly 432 and the second track assembly 436. For example, a second trolley assembly 460, currently at the exit position 458 and blocking the first trolley assembly 456 from the exit position 458, may be moved along the first track assembly 432 using the friction drive system 270 and onto the first movable track assembly 444. The first movable track assembly 444 may then be raised, using the first programmable hoist 446, from the first position to the second position (shown). At the second position of the first movable track assembly 444, the second trolley assembly 460 may be moved from the first movable track assembly 444 and onto the second track assembly 436, using the friction drive system 270. As a result, the first trolley assembly 456 may be moved along the first track assembly 432 and into the exit position 458.

It should be appreciated that, in the exemplary operation described above, the second track assembly 436 was not at its illustrated capacity of three trolley assemblies 434 and, therefore, the second trolley assembly 460 could more easily be moved onto the second track assembly 436. However, if the second track assembly 436 were supporting a maximum number of trolley assemblies 434, it may be necessary to move one of the trolley assemblies 434 from the second track assembly 436 to the first track assembly 432. For example, the second movable track assembly 450 may be moved from the first position
(shown) to the second position, described above. Next, a third trolley assembly 462 may be moved along the second track assembly 436 and onto the second movable track assembly 450. The second movable track assembly 450 may then be lowered, such as by using the second programmable hoist 454, from the second position to the first position, such that the third trolley assembly 462 may be moved from the second movable track assembly 450 and onto the first track assembly 432.

It should also be appreciated that, if both the first track assembly 432 and the second track assembly 436 are at maximum capacity, trolley assemblies 434 may be simultaneously moved, or shifted, through the buffer 430. For example, the friction drive system 270 of the first track assembly 432 may transport the trolley assemblies 434 in a first direction, while the friction drive system 270 of the second track assembly 436 may transport the trolley assemblies 434 in a second direction that is opposite the first direction. Specifically, the trolley assemblies 434 may be shifted in clockwise direction or a counterclockwise direction through the buffer 430 to move a desired trolley assembly 434 to the exit position 458. As should be appreciated, to provide such re-sequencing when the buffer 430 is at, or near, maximum capacity, it may be preferable to utilize at least two or more movable track assemblies, such as movable track assemblies 444 and 450. Further, it should be appreciated that the friction drive system 270 or, more specifically, friction drive modules corresponding to each of the track assemblies 432, 436, and 438 and movable track assemblies 444 and 450 may provide independent movement and control of each of the trolley assemblies 434 positioned therein.

Turning now to Figure 13, a high level view of a first line 480 is shown. The first line 480 may be similar to, or may include, the modular manufacturing chain 10 described above with reference to Figure 1. Specifically, the first line 480 may include a plurality of stationary modules, such as modules 32 (Figures 1-5) or modules 360 (Figure 10), positioned in series, or in parallel,
and defining at least one path 481, which may include a main path, through the first line 480. The first line 480 may utilize the material handling system 250, as described above, including one or more composite beams 252 supporting the friction drive system 270. Generally, according to one example, the first line 480 may include first operations 482 and a logistics area 484, both of which may receive articles, such as parts, from suppliers 486. From first operations 482, parts, or other articles, may be transported to fabrications 488, using the material handling system 250, by supporting the parts using carriers, as described above. From both logistics 484 and fabrications 488, articles may be transported to paint shop 490 or sub-assembly 492.

As shown, the first line 480 may include a plurality of buffers 494, which may be similar to the buffer 430 described above with reference to Figure 12. The buffers 494 may be positioned anywhere along the first line 480, such that carriers, and articles supported thereon, may be routed off the one or more main paths 481 and into the buffers 494. As described above, the buffers 494 may be used to store and/or re-sequence carriers and/or articles. A plurality of spurs 495 may also be provided throughout the first line 480 for storing and/or re-sequencing carriers, in a manner described in greater detail below. Further, the articles may remain on the same carriers continuously throughout the first line 480, which may span one or more buildings or manufacturing areas. For example, parts and/or sub-assemblies may be stored in one of the buffers 494, or other storage areas, until they are transported, such as by using a trolley assembly 496, similar to those described above, to an assembly line 498 or to one or more stations 500 along the assembly line 498. The articles and/or carriers may be tracked, such as by using barcodes, sensors, and the control system 220 described above, to access and route the parts to the assembly line 498 and/or stations 500 precisely when they are needed.

A mobile module 502, having ground-engaging elements 504, may be used to transport an article, such as a part, sub-assembly, or assembly,
from the first line 480 to a second line 520, as shown in Figure 14. Specifically, the mobile module 502 may be movable between, at least, a first position 506, as shown in Figure 13, to a second position 522, as shown in Figure 14. The mobile module 502 may include one or more modules, such as modules 32 (Figures 1-5) or 360 (Figure 10) supported by a frame, such as an enclosed portion of a vehicle or other mobile device. For example, the mobile module 502 may represent a mobile version of one of the stationary modules 32 or 360 described above, and may be movable using any known transportation means. The mobile module 502 may also include a material handling system 250, including one or more composite beams 252 supporting a friction drive system 270, as described above.

It should be appreciated that in both the first position 506 and the second position 522, the material handling system 250 of the mobile module 502 may be aligned with a portion of the material handling system 250 of the respective line 480 or 520, such that a trolley assembly, such as trolley assembly 492, may be continuously transported along the respective material handling systems 250. According to another embodiment, the material handling system 250 may provide a continuous path between adjacent buildings. Further, an enclosure may be provided to protect the material handling system 250 and any articles transported thereon from the weather, and other adverse conditions, to which they may be exposed between buildings. As should also be appreciated, transporting an article on its respective carrier may allow the carrier and, thus, article to be tracked while it is transported between remote buildings, locations, etc., as described herein.

Referring also to Figures 1-13, the second line 520 of Figure 14 may also include a plurality of stationary modules 32 or 360 positioned in series and defining at least one path through the second line 520. The second line 520 may utilize the material handling system 250, as described above, including one or more composite beams 252 supporting a friction drive system 270. Generally, the second line 520 may include one or more track switches, which may each be
positioned between two of the plurality of drive tubes 268. According to one example, a first track switch 524, which may include a movable track assembly 525, may be movable between a first position defining a first path 526, and a second position defining a second path 528. As shown, the second path 528 may be positioned at an angle that is greater than zero with respect to the first path 526. By moving the first track switch 524 from the first position to the second position, a carrier, such as carrier 530, may be transported through the first track switch 524 and onto a spur 532 (as shown). It should be appreciated that the spur 532, and additional spurs, may be positioned along the second line 520 and used for temporary storage and/or carrier re-sequencing. For example, the carrier 530 may be routed onto the spur 532, the first track switch 524 may be moved back to the first position, and one or more additional carriers, such as carrier 534, may proceed along the first path 526 in advance of carrier 530.

The spur 532 may also provide a means for turning carriers around. For example, the carrier 530 may be transported, such as in a forward direction, along the second path 528 and past a second track switch 534. The second track switch 534 may also include a movable track assembly 536 that is movable between a first position defining the second path 528 and a second position defining a third path 538. After the carrier 532 is moved along the second path 528 and past the second track switch 534, the second track switch 534 may be moved to the second position, such that the carrier 532 may be moved, in a reverse direction, along the third path 538. Further, a third track switch 540, also including a movable track assembly 542, may be movable between a first position defining the first path 526 and a second position defining the third path 538. Thus, when the third track assembly 540 is in the second position, the carrier 532 may be transported from the spur 532, in the reverse direction, and back along the first path 526, with the article supported by carrier 530 having an orientation that is 180° opposite its previous orientation.
Additional means for turning around a carrier, such as the carrier 530, may include movement of a track assembly using a known gantry track, or crane. Specifically, for example, a gantry track, which may provide a fixed structure about which the track assembly may be pivoted, may be used alone or in combination with one or more track switches to reposition a track assembly with respect to a main path, such as the first path 526. Due to the modularity of the material handling system 250, gantry tracks, which may be traveling, portable, or fixed, may also be used to move a carrier, such as carrier 530, between one or more alternative paths, thus operating as a shuttle. Such a shuttle, as should be appreciated, may be used to align a movable track assembly with one of a plurality of track assemblies, thus providing alternative paths for the carrier 530.

Track switches, as described above, may be incorporated along the second line 520 for additional purposes. For example, a track switch, such as a fourth track switch 544 having a movable track assembly 546, may be used to transition a carrier, such as carrier 548, onto a dual track assembly, which may be similar to the dual track assembly described above with reference to Figures 11a and 11b. For example, a first trolley assembly 550, supporting the carrier 548 may be transported through the fourth track switch 544 and along the first path 526, while the fourth track switch 544 is in a first position. The fourth track switch 544 may then be moved into a second position, which defines a fourth path 552. As such, a second trolley assembly 554 may be transported along the fourth path 552, which may be substantially parallel to the first path 526. It should be appreciated that movement of the first trolley assembly 550 and the second trolley assembly 554 may be controlled to position the carrier 548, and the one or more articles supported thereon, at any desired angle with respect to the direction of travel. As should be appreciated, there may be one or more modules 360 through which it may be desirable to transport articles at alternative angles, such as, for example, paint or wash modules. Further, it should be appreciated that such diagonal orientation of the carrier 548 may be useful when
storing a plurality of carriers, similar to carrier 548, along a spur, such as spur 532, or within a buffer, such as buffer 430. Specifically, a substantial amount of space may be saved by accumulating carriers, such as carrier 548, at diagonal orientations relative to the direction of travel by providing the dual paths 526 and 552 and track switch 544, as described above.

After transporting the carrier 548 through one or more modules 360 at an alternative angle with respect to the direction of travel, a fifth track switch 556 may be positioned along the second line 520 to return the second trolley assembly 554 to the first path 526. Track switches, such as a sixth track switch 558, may also be used to route carriers through one or more alternative paths through the second line 520. For example, the sixth track switch 558 may be used to route carriers along either of the first path 526 and a fifth path 560. As shown, the first path 526 may include one or more curves, such as curves 562 and 564. To navigate around such curves, according to one embodiment, a first trolley assembly 564 of a carrier 566 may be disengaged from a first drive tube 568, while a second trolley assembly 570 of the carrier 566 may be engaged with the first drive tube 568. As such, the first trolley assembly 564 may be pushed around the curve 562 using the second trolley assembly 570. As the carrier 566 travels through the curve 562, the first trolley assembly 564 may engage a second drive tube 572. The second trolley assembly 570 may eventually disengage from the first drive tube 568, thus allowing the first trolley assembly 564 to pull the second trolley assembly 570 around the curve 562. Specifically, for example, such curves 562 may be navigated by positioning drive tubes 568 and 572, such as linear drive tubes, such that at least one trolley assembly 564 or 570 continuously engages one of the drive tubes 568 and 572.

If a carrier, such as a carrier 574, is transported along the fifth path 560, a first trolley assembly 576 and a second trolley assembly 578 may ultimately transition the carrier 574 around a curve 580. When the carrier 574 is positioned along the curve 580, and the first trolley assembly 576 and the second
trolley assembly 578 are stopped, ends 582 and 584 of the carrier 574 may extend beyond a perimeter 586 defined by the curve 580. When positioned as shown, the carrier 574 may be removed from the fifth path 560 using a programmable hoist 588. The programmable hoist 588, which may be of conventional design, may include one or more track assemblies 590 along which the programmable hoist 588 may be movable. Specifically, the programmable hoist 588 may move the carrier 574, and the article supported thereon, through one or more modules 360, lowering and raising the carrier 574, as necessary. The programmable hoist 588, according to one embodiment, may be supported on its own carrier, which may be supported by one or more trolleys that are movable along track assemblies 590, as described herein. More specifically, the carrier and trolleys supporting the programmable hoist 588 may operate as a bridge crane moving along the track assemblies 590, which may serve as runways for the bridge crane. Further, a track assembly, such as track assemblies 590 including one or more composite beams 252, may be used as the bridge between the runways. Yet further, one of the track assemblies described herein may be configured as a gantry crane, in which one end of the track assembly is pivotable about the other.

After the carrier 574 is transported through one or more modules 360 using the track assemblies 590 and programmable hoist 588, the carrier 574, and article supported thereon, may again be supported on one or more trolley assemblies. Specifically, the carrier 574 may be supported by a first trolley assembly 592 and a second trolley assembly 594, when the first trolley assembly 592 and the second trolley assembly 594 are positioned around a curve 596 of a sixth path 598. The sixth path 598 may be positioned to route the carrier back to the first path 526, as shown. It should be appreciated that the article may remain on the same carrier 574 throughout the transition of the carrier 574 to and from the programmable hoist 588. It should also be appreciated that this transition, and others described herein, are intended as examples only and, therefore, should
not limit the second line 520, or material handling system 250 thereof, in any way.

An additional spur 600 may be positioned along the second line 520 to store and/or re-sequence carriers, as described above. Specifically, a seventh track switch 602 and an eighth track switch 604 may be movable to route one or more carriers into and out of the spur 600. As shown, one or more modules 360 positioned along the spur 600, and/or other modules, may include a zigzag support frame 606. Specifically, as an alterative to the end frames 362 and mid-frame 364 of Figure 10, one or more modules 360 may include beams 608, or headers, that are oriented at an angle, or cross-oriented, with respect to a travel direction through the module 360. The beams 608 may be attached to end posts 368, as shown, and may support one or more composite beams 252, as described above. Although the modules 360 are shown as including two cross-oriented beams 608, it should be appreciated that each module 360 may include only one beam having an angled orientation with respect to the direction of travel. For example, consecutive modules 360 may include headers, or beams, that are oriented at alternative angles, but that define a continuous zigzag support structure through the modules 360. Such arrangements, as should be appreciated, may require fewer beams and, therefore, less material for construction of modules 360. Further, in addition to reduced material cost, such arrangements, utilizing fewer beams, may require less time for assembly of the modules 360.

A shuttle, such as a lateral shuttle 610, may be positioned at an end 612 of the second line 520, as shown. According to one embodiment, the lateral shuttle 610 may include one or more trolley assemblies, such as any of the trolley assemblies described herein, that are movable along one or more track assemblies, also described herein. The trolley assemblies may support an additional track assembly 614, oriented perpendicular to the track assemblies along which the trolley assemblies are moved, which is movable to define alternative paths. According to the exemplary embodiment, for example, the
track assembly 614 may include a position defining a seventh path 616, a position
defining a continuous path along the first path 526 (shown), and a position
defining an eighth path 618. However, as should be appreciated, such a shuttle
610 may be movable to define any number of alternative paths for one or more
carriers, such as a carrier 620, positioned thereon.

According to the illustrated embodiment, the track assembly 614
may be moved, such as by using the shuttle 610, to align with the eighth path 618
of the second line 520. When the track assembly 614 is positioned to define a
continuous path, the carrier 620, and article supported thereon, may be moved
onto the eighth path 618. As shown, the eighth path 618 may also include a
curve 622, from which the article may be removed from the second line 520.
According to one example, the article may be removed from the second line 520
only for delivery to a customer. Alternatively, however, the article may be
transported to a customer using the mobile module 502, as described herein. If
the article is removed from the carrier 620, the empty carrier 620, according to
one embodiment, may be returned to the track assembly 614. The shuttle 610
may then be used to move the track assembly 614 to align with the seventh path
616, which may route the empty carrier 620 to one or more desired locations,
such as, for example, a storage buffer 624, which may be similar to the buffer
430 of Figure 12. According to one example, the seventh path 616 may include
one or more composite beams 252, described herein, which may be supported
from one or more modules 360. Specifically, one or more modules 360 may
support one or more composite beams 252 defining a first path through the
modules 360, and one or more composite beams 252 defining an additional path
adjacent the modules 360 for empty carrier returns.

It should be appreciated that alternative arrangements may be used
for carrier, or empty carrier, returns. For example, a buffer, such as the buffer
430 described above, may be used to define a first, main, path and a second,
return, path. One or more movable track assemblies, such as movable track
assemblies 444 and 450 of Figure 12, may be used to transition carriers from the main path to the return path, in a manner similar to that described above. Such transitions, also referred to as an over-under conveyance, may be incorporated, as needed, into the first line 480 and/or the second line 520. For example, one of the stationary track assemblies of the buffer 430 of Figure 12 may be positioned along a main path, such as the main path 481 of the first line 480 or the first path 526 of the second line 520. Alternatively, one or more carriers may be routed off the main path 481 or first path 526 and into the buffer 430, such as by actuating one or more track switches, as described herein.

The carrier 620 may, alternatively, be routed through the shuttle 610 along the first path 526 and, for example, onto a mobile module, such as the mobile module 502. In a third position 626 (shown) of the mobile module 502, the material handling system, such as material handling system 250 described herein, of the mobile module 502 may be aligned with the material handling system 250 of the second line 520 such that the carrier 620 may be continuously transported from the first path 526 and onto the mobile module 502. From there, the mobile module 502 may return the carrier 620, and article supported thereon, to the first line 480. It should be appreciated that the first line 480 and the second line 520 may represent one or more manufacturing lines positioned in adjacent buildings or, alternatively, at remote locations.

The modular material handling system 250, as described herein with reference to the preceding figures, may be used as a common material handling system throughout an entire manufacturing, or production, process. For example, the material handling system 250 may be used throughout the first line 480 (Figure 13), the second line 520 (Figure 14), and any number of mobile modules 502 that may be configured to transport articles between the first line 480 and the second line 520. Specifically, the same material handling system 250 may be used to route an article through all of the implemented manufacturing processes, including, for example, first operations 482, logistics 484, fabrications
488, paint 490, sub-assembly 492, and assembly 498 of the first line 480. Although specific examples are provided, it should be appreciated that the modular material handling system 250, as described herein, may be used to support any number and/or combination of manufacturing processes.

Further, the configuration of the material handling system 250, including composite beams 252 and friction drive system 270, as shown in Figure 8, may provide a modular material handling system that may be relatively quickly and easily assembled and/or modified. Specifically, as described with reference to Figure 10, each of a plurality of manufacturing modules 360 may be assembled by connecting a mid-frame 364 to a pair of end frames 362, and supporting a pre-constructed composite beam 252 from the interconnected frames using one or more connecting clamps 366. The friction drive system 270, and other systems or controls, may be supported from the module 360 and, further, may be connected to any necessary utilities via a utility transfer module 40, as described above. Further, an Andon system, as is known in the art, may be integrated with the any of manufacturing lines 10, 480, and 520 and, further, with the control system 220. For example, a visual indication of a problem identified, either manually or automatically, at a specific module 32 or 360 may be provided. It should be appreciated that the systems, controls, and equipment used herein may all be provided with plug and play functionality to further ease assembly and/or modification of the manufacturing modules 360.

The composite beams 252, embodiments of which are illustrated in Figures 9a-9c, and friction drive system 270 of material handling system 250 may support a wide range of weights. Specifically, for example, the composite beams 252 may support any of a variety of articles, ranging from small parts to large sub-assemblies, using one or more trolleys 262 of the friction drive system 270, which may be configured to directly or indirectly support articles. By supporting such a wide range of weights, the material handling system 250 may be used in a variety of industries, and throughout processes that normally
integrate multiple material handling systems or devices, including forklifts, to transport both small and large articles. According to one example, the material handling system 250, as described herein, may be used to transport both large sub-assemblies and small parts along the main path 481 of the first line 480 (Figure 13). Specifically, for example, a large sub-assembly may be transported from sub-assembly 492 to the assembly line 498 along path 481, while a plurality of small parts may be transported from one of the buffers 494 to stations 500 along the same path 481. Alternatively, either or both of the first line 480 and the second line 520 may integrate a material handling system 250 sized to support lighter weights with a material handling system 250 sized to support heavier weights. Further, such embodiments may incorporate weigh stations along the material handling systems 250 to ensure that trolleys 262 are not routed along paths incapable of providing sufficient support. Alternatively, a control system, such as the control system 220 described above, may track the weight of each article transported along the one or more integrated material handling systems 250 and route respective trolleys 262 accordingly.

To increase the versatility of the material handling system 250, a variety of devices and/or features, including, but not limited to track switches, spurs, buffers, programmable hoists, shuttles, and gantry tracks, examples of which are provided herein, may be integrated with the material handling system 250, as described above. As should be appreciated, these devices and/or features may be utilized by the material handling system 250 to provide numerous and useful transitions of articles throughout a manufacturing, or production, process. Further, the material handling system 250, and devices or features incorporated therein, may be integrated with a control system, such as the control system 220, to coordinate the processes for and movements of each article transported along the material handling system 250. Specifically, by tracking and controlling each article, flow throughout the manufacturing process can be better organized, thus reducing waste and improving efficiency.
Industrial Applicability

The manufacturing chain 10 of the present disclosure may provide a portable and flexible manufacturing chain that supports an improved manufacturing process. Specifically, the manufacturing chain 10 includes manufacturing modules 32 that may be relatively quickly and easily transported and deployed. In addition, modular manufacturing stations 18, 20, 22, 24, 26, and 28 may be readily added to and/or removed from the modules 32 of the manufacturing chain 10. Further, the article transportation system 30, and method of operation thereof, may allow independent process control at each modular manufacturing station 18, 20, 22, 24, 26, and 28 and, therefore, may provide improved efficiency with respect to the manufacturing process.

Although a paint process is described, it should be appreciated that the manufacturing chain 10, as described herein, may be used to perform any of a variety of manufacturing processes.

Referring generally to Figures 1-14, the manufacturing chain 10, such as, for example, a paint line, may be deployed by erecting a plurality of manufacturing modules 32, as needed. Specifically, a plurality of support beams 82, 84, 86, 88, 98, 100, 102, and 104 may be secured to the planar floor 16 of a manufacturing area 12 and may be interconnected to provide a framework or skeleton 80. One or more of the support beams support beams 82, 84, 86, 88, 98, 100, 102, and 104 may be capable of expansion and/or contraction to further ease the transport and/or deployment of each manufacturing module 32. The skeleton 80 may provide structural support for one or more modular manufacturing stations, such as, for example, the first modular manufacturing station 118 and the second modular manufacturing station 160 and/or the modular manufacturing stations 18, 20, 22, 24, 26, and 28. Further, the skeleton may include pre-constructed utilities, namely a utility transfer module 40, supported by one or more of the support beams 82, 84, 86, 88, 98, 100, 102, and 104.
Each modular manufacturing station, such as stations 118 and 160, may include at least one piece of manufacturing equipment 120, an article transportation device 122 representing a portion of the article transportation system 30 corresponding to the respective station, and a station control system 124. It should be appreciated that the manufacturing equipment 120 may be positioned above the planar floor 16 and may be portable to facilitate movement of the equipment 120 from one location, such as a storage location, and into an operable position relative to the station. The manufacturing equipment 120, as well as the article transportation device 122, the station control system 124, and various other systems and/or components of each station 118 and 160 may receive one or more utilities from the utility transfer module 40.

It should be appreciated that modifying the manufacturing chain 10, such as adding or removing a modular manufacturing station may also be accomplished with relative ease. Specifically, a modular manufacturing station, similar to manufacturing stations 116 and 180, may be added to the manufacturing chain 10 by interconnecting a plurality of beams 82, 84, 86, 88, 98, 100, 102, and 104 to form a skeleton 80. The skeleton 80 may be connected to or, alternatively, positioned adjacent a contiguous manufacturing module 32. A utility transfer module 40, which may be supported by one of the beams 82, 84, 86, 88, 98, 100, 102, and 104, may be connected to a utility transfer module 40 of the contiguous manufacturing module 32 to provide utilities to the added manufacturing station.

One or more of an article transportation device 122, a piece of manufacturing equipment 120, and a station control system 124 may be supported by the skeleton 80, or otherwise positioned within an operable distance of the added manufacturing station. In addition, one or more of the article transportation device 122, the manufacturing equipment 120, and the station control system 124 may be connected to the utility transfer module 40 to receive
one or more utilities therefrom, such as using quick connect coupling members, as described above.

Operation of the manufacturing chain 10 may be controlled and/or coordinated using the control system 220. Specifically, one or more of the main control system 230 and the station control systems 124 may be configured to advance at least one carrier 164 from a beginning of the manufacturing chain 10 to an end of the manufacturing chain 10, such as in the forward transport direction "F." This advancement, according to a specific example, may include independently moving a carrier 164 of the first modular manufacturing station 118 according to a first unique operation pattern and a carrier 164 of the second modular manufacturing station 160 according to a second unique operation pattern. According to one embodiment, the first unique operation pattern may include the forward transport direction "F" and the reverse transport direction "R." The second unique operation pattern may, for example, include moving the carrier 164 in the vertical direction relative to the transportation path 166, such as by raising and/or lowering the carrier 164.

The memory 234 of the main control system 230 may store the first and second unique operation patterns for controlling operation of the first and second modular manufacturing stations 118 and 160, respectively, thereon. The first position tracking devices 176 of each modular manufacturing station 118 and 160 may detect a first position of each carrier 164 as it is transported through the respective one of the manufacturing stations 118 and 160, and transmit first position signals to the main control system 230. It should be appreciated that any of the operation signals, including position signals, may be transmitted through the station control systems 124.

The processor 232 of the main control system 230 may be configured to independently transmit an operation signal corresponding to each of the first and second unique operation patterns to the respective one of the manufacturing stations 118 and 160 based, at least in part, on the detected first
positions. For example, the processor 232 may independently transmit one or more operation signals, such as, for example, the forward signal, to each article transportation device 122 upon detecting that each carrier 164 is entering the respective one of the modular manufacturing stations 118 and 160. Similarly, the processor 232 may be configured to independently transmit one or more operation signals to the manufacturing equipment 120 based, at least in part, on the detected first positions.

In addition, the second position tracking devices 178 and the third position tracking devices 180 of the manufacturing stations 118 and 160 may detect second and third positions, respectively, and transmit second and third position signals to the main control system 230, such as through the station control systems 124. The processor 232 may also be configured to independently transmit an operation signal corresponding to each of the first and second unique operation patterns to the respective one of the manufacturing stations 118 and 160 based, at least in part, on one of the detected second and third positions. Similarly, the processor 232 may be configured to independently transmit one or more operation signals to the manufacturing equipment 120 based, at least in part, on one of the detected second and third positions.

For example, the processor 232 may be configured to transmit the reverse signal to the article transportation device 122 of the first modular manufacturing station 118 upon detecting that the carrier 164 has reached a predetermined position relative to the manufacturing equipment 120. Similarly, the processor 232 may be configured to transmit the lower signal to the article transportation device 122, or second vertical lift device 212, of the second modular manufacturing station 160 upon detecting that the carrier 164 has reached a predetermined position relative to the manufacturing equipment 120. Determining that the carrier 164 has reached the predetermined position, in either example, may be based, at least in part, on one of the second and third position signals.
In addition, the processor 232 of the main control system 230 may be configured to index the carriers 164 of each modular manufacturing station 118 and 160 as each carrier 164 traverses to a contiguous manufacturing station. Indexing may, for example, include detecting one of the second and third positions, as described above, of each carrier 164 and simultaneously transferring each carrier 164 to a contiguous manufacturing station.

It should be appreciated that manufacturing chain 10, including a plurality of modular manufacturing stations 18, 20, 22, 24, 26, and 28, as described herein, may be deployed and/or modified with relative ease. Each modular manufacturing station 18, 20, 22, 24, 26, and 28, as further exemplified by first and second modular manufacturing stations 118 and 160, is characterized as having a separate article transportation device 122 that allows each carrier 164 to move independently through the respective station. The control system 220 coordinates the independent movements occurring at each station 18, 20, 22, 24, 26, and 28 and synchronizes the transfer of each carrier 164 to a contiguous one of the modular manufacturing stations to define one overlying process flow for the manufacturing chain 10.

It should be understood that the above description is intended for illustrative purposes only, and is not intended to limit the scope of the present disclosure in any way. Thus, those skilled in the art will appreciate that other aspects of the disclosure can be obtained from a study of the drawings, the disclosure and the appended claims.
Claims

1. A material handling system (250), comprising:
   a composite beam (252) including an upper rail (254) and a lower track (256) connected through a plurality of spaced apart transverse members (258), the lower track (256) defining two parallel channels (260);
   a trolley (262) having an upper set of wheels (266) and a lower set of wheels (264), the lower set of wheels (264) received within the two parallel channels (260);
   a drive tube (268) positioned between the upper rail (254) and the lower track (256) such that the upper set of wheels (266) are in frictional engagement with the drive tube (268); and
   a drive system (270) configured to rotate the drive tube (268).

2. The material handling system (250) of claim 1, wherein each of the plurality of transverse members (258) includes an inverted U-shaped cross-section defining a pair of free ends (320), each of the pair of free ends (320) supporting a C-shaped channel (260) of the lower track (256).

3. The material handling system (250) of claim 2, wherein the upper rail (254) includes a T-shaped cross-section defining a central web (322) and a transverse flange (324), the central web (322) being received within a vertically aligned slot (326) of an upper portion (328) of each of the plurality of transverse members (258).

4. The material handling system (250) of claim 2, wherein the upper rail (254) includes a pair of oppositely oriented structural members (330), each of the pair of oppositely oriented structural members (330) having a
vertically oriented web (332) secured to each of the plurality of transverse members (258).

5. The material handling system (250) of claim 4, further including a horizontally aligned support plate (336) secured to each of the pair of free ends (320) of the plurality of transverse members (258).

6. A method of operating a material handling system (250), comprising:

   transporting a trolley (262) having an upper set of wheels (266) and a lower set of wheels (264) along the material handling system (250), at least in part, by:

   supporting the lower set of wheels (264) of the trolley (262) within two parallel channels (260) defined by a lower track (256);

   frictionally engaging the upper set of wheels (266) of the trolley (262) with a drive tube (268);

   rotating the drive tube (268) to move the lower set of wheels (264) within the two parallel channels (260); and

   supporting a weight carried by the trolley (262) with a composite beam (252) including an upper rail (254) and the lower track (256) connected through a plurality of spaced apart transverse support members (258).

7. The method of claim 6, wherein the transporting step includes distributing a weight carried by a first carrier (296, 394, 548, 566, 574) between at least a first trolley (274, 382, 550, 564, 576, 592) and a second trolley (285, 388, 554, 570, 578, 594).

8. The method of claim 7, wherein the transporting step further includes continuously engaging at least one of the first trolley (274, 382, 550,
564, 576, 592) and the second trolley (285, 388, 554, 570, 578, 594) with one of a plurality of drive tubes (268).

9. The method of claim 8, wherein the transporting step further includes transporting the first carrier (566) around a curve (562), at least in part, by:

   engaging the second trolley (570) with a first drive tube (568);
   disengaging the first trolley (564) from the first drive tube (568);
   pushing the first trolley (564) around the curve (562) using the second trolley (570);
   engaging the first trolley (564) with a second drive tube (572);
   disengaging the second trolley (570) from the first drive tube (568); and
   pulling the second trolley (570) around the curve (562) using the first trolley (564).

10. The method of claim 8, wherein the transporting step further includes:

   transporting the first carrier (534) along a first path (526);
   actuating a first track switch (524) positioned between two of the plurality of drive tubes (268); and
   transporting the first carrier (534) through the first track switch (524) and along a second path (528) having an angle greater than zero with respect to the first path (526).
