(54) Titre : SYSTEMES ET PROCEDES POUR ESTIMER DES NUMERATIONS PLAQUETTAIRES
(54) Title: SYSTEMS AND METHODS FOR ESTIMATING PLATELET COUNTS

(57) Abrégé/Abstract:
Systems and methods take into account that the spleen normally holds a number of platelets in reserve out of circulation. During blood processing, the spleen releases these platelets into the donor's circulatory system, making them available for collection. The systems and methods estimate the number of platelets $N_{\text{SPL}}$, held in reserve by the spleen in a human body. The systems and methods derive a splenic mobilization function Spleen, which can be expressed as a function of a precount of platelets $N_{\text{PLT}}$. The systems and methods estimate $N_{\text{SPL}}$ where: $N_{\text{SPL}} = \text{Spleen-1} \times N_{\text{PLT}} \times \text{DonVol}$ where DonVol is blood volume in the body. The systems and methods can also estimate the total number of platelets $N_{\text{PLT}}$ in a human body, taking the Spleen function into account, where: $N_{\text{PLT}} = N_{\text{PLT}} \times \text{Spleen} \times \text{DonVol}$.
SYSTEMS AND METHODS FOR ESTIMATING PLATELET COUNTS

Systems and methods take into account that the spleen normally holds a number of platelets in reserve out of circulation. During blood processing, the spleen releases these platelets into the donor’s circulatory system, making them available for collection. The systems and methods estimate the number of platelets \( N_{SPL} \) held in reserve by the spleen in a human body. The systems and methods derive a splenic mobilization function \( Spleen \), which can be expressed as a function of a precount of platelets \( P_{PRA} \). The systems and methods estimate \( N_{SPL} \) where:

\[
N_{SPL} = Spleen - 1 \times P_{PRA} \times DonVol
\]

where DonVol is blood volume in the body. The systems and methods can also estimate the total number of platelets \( N_{PLT} \) in a human body, taking the \( Spleen \) function into account, where:

\[
N_{PLT} = P_{PRA} \times Spleen \times DonVol.
\]
"SYSTEMS AND METHODS
FOR ESTIMATING PLATELET COUNTS".

Field of the Invention

The invention generally relates to blood processing systems and methods.

Background of the Invention

Today people routinely separate whole blood by centrifugation into its various therapeutic components, such as red blood cells, platelets, and plasma.

Certain therapies transfuse large volumes of blood components. For example, some patients undergoing chemotherapy require the transfusion of large numbers of platelets on a routine basis. Manual blood bag systems simply are not an efficient way to collect these large numbers of platelets from individual donors.

On line blood separation systems are today used to collect large numbers of platelets to meet this demand. On line systems perform the separation steps necessary to separate concentration of platelets from whole blood in a sequential process with the donor present. On line systems establish a flow of whole blood from the donor, separate out the desired platelets from the flow, and return the remaining red blood cells and plasma to the donor, all in a sequential flow loop.

Large volumes of whole blood (for example, 2.0 liters) can be processed using an on line
system. Due to the large processing volumes, large yields of concentrated platelets (for example, $4 \times 10^{11}$ platelets suspended in 200 ml of fluid) can be collected. Moreover, since the donor's red blood cells are returned, the donor can donate whole blood for on line processing much more frequently than donors for processing in multiple blood bag systems.

Nevertheless, a need still exists for further improved systems and methods for collecting cellular-rich concentrates from blood components in a way that lends itself to use in high volume, on line blood collection environments, where higher yields of critically needed cellular blood components like platelets can be realized.

As the operational and performance demands upon such fluid processing systems become more complex and sophisticated, the need exists for automated process controllers that can gather and generate more detailed information and control signals to aid the operator in maximizing processing and separation efficiencies.

**Summary of the Invention**

One aspect of the invention provides systems and methods for estimating the number of platelets $N_{\text{Spleen}}$ held in reserve by the spleen in a human body. The systems and methods receive a precound of platelets in the body ($\text{Plt}_{\text{PRE}}$). The systems and methods derives a splenic mobilization function ($\text{Spleen}$), which takes into account the number of platelets normally held in reserve by the spleen, where:

$$\text{Spleen} = f(\text{Plt}_{\text{PRE}})$$

According to another aspect of the invention, there is provided a system for separating platelets from blood comprising:

- a separation device for separating blood into plasma and platelets;
- an inlet to the separation device to convey anticoagulated blood containing plasma and platelets from a donor into the separation device for separating into a plasma yield and a platelet yield; and
a processing element coupled to the separation device including a first element that estimates, at least in part while separation occurs in the separation device, the total number of platelets $N_{PLT}$ available for collection from the donor by a method comprising the steps of:

5 determining a precount of platelets ($Plt_{PRE}$) in the donor;

deriving a splenic mobilization function ($Spleen$) where

$Spleen = f(Plt_{PRE})$; and

deriving $N_{PLT}$ where $N_{PLT} = Plt_{PRE} \times Spleen \times DonVol$

where:

10 $DonVol$ is blood volume in the donor’s body,

the processing element further including an output to output $N_{PLT}$.

According to yet another aspect of the invention, there is provided a method for estimating the total number of platelets $N_{PLT}$ in a human body comprising the steps of:

15 measuring a precount of circulating platelets in the body ($Plt_{PRE}$);

estimating a splenic mobilization function ($Spleen$) where $Spleen = f(Plt_{PRE})$;

estimating $N_{PLT}$ where $N_{PLT} = Plt_{PRE} \times Spleen \times DonVol$

where:

20 $DonVol$ is a blood volume in the donor’s body; and

generating an output based upon $N_{PLT}$.

According to still yet another aspect of the invention, there is provided a device that estimates the total number of platelets $N_{PLT}$ in a human body comprising

25 an input for receiving a precount of platelets in the body ($Plt_{PRE}$); and
a processor coupled to the input including:

an element that derives a splenic mobilization function

\( Spleen = f(PLt_{PRE}) \)

and

an element that estimates \( N_{PLT} \) where:

\( N_{PLT} = PLt_{PRE} \times Spleen \times DonVol \)

where:

Donvol is blood volume in the body; and

an output coupled to the processor to output \( N_{PLT} \).

The systems and methods that embody the features of the invention take into account that the spleen normally holds a number of platelets in reserve out of circulation. During blood processing, the spleen releases these platelets into the donor's circulatory system, making them available for collection. Conventional practices, which rely upon a current precount of circulating platelets without taking into account the number of platelets held in reserve by the spleen, underestimate the actual number of platelets that are available for collection. Use of the spleen mobilization function allows one to maximize platelet yields during blood component processing.

In a preferred embodiment, a curve estimates the \( Spleen \) function, expressed as follows:
\[ Spleen = a - b(Plt_{PRE}) \]

where:
\( a \) is the y-intercept of the curve, and
\( b \) is the slope of the curve. In the preferred embodiment, the systems and methods derive the spleen mobilization function using \( a \approx 2.25 \) and \( b \approx 0.004 \).

The various aspects of the invention are especially well suited for on line blood separation processes.

Other features and advantages of the invention will become apparent from the following description, the drawings, and the claims.

**Brief Description of the Drawings**

Fig. 1 is a diagrammatic view of a dual needle platelet collection system that includes a controller that embodies the features of the invention;

Fig. 2 is a diagrammatic flow chart view of the controller and associated system optimization application that embodies the features of the invention;

Fig. 3 is a diagrammatic view of the function utilities contained within the system optimization application shown in Fig. 2;

Fig. 4 is a diagrammatic flow chart view of the utility function contained within the system optimization application that derives the yield of platelets during a given processing session;

Fig. 5 is a diagrammatic flow chart view of the utility functions contained within the system optimization application that provide processing status and parameter information, generate control
variables for achieving optimal separation efficiencies, and generate control variables that control the rate of citrate infusion during a given processing session;

Fig. 6 is a diagrammatic flow chart view of the utility function contained within the system optimization application that recommends optimal storage parameters based upon the yield of platelets during a given processing session;

Fig. 7 is a diagrammatic flow chart view of the utility function contained within the system optimization application that estimates the processing time before commencing a given processing session;

Fig. 8 is a graphical depiction of an algorithm used by the utility function shown in Fig. 4 expressing the relationship between the efficiency of platelet separation in the second stage chamber and a dimensionless parameter, which takes into account the size of the platelets, the plasma flow rate, the area of the chamber, and the speed of rotation;

Fig. 9 is a graph showing the relationship between the partial pressure of oxygen and the permeation of a particular storage container, which the utility function shown in Fig. 6 takes into account in recommending optimal storage parameters in terms of the number of storage containers;

Fig. 10 is a graph showing the relationship between the consumption of bicarbonate and storage thrombocytocrit for a particular storage container, which the utility function shown in Fig. 6 takes into account in recommending optimal storage parameters in terms of the volume of plasma storage medium; and
Fig. 11 is a graph showing the efficiency of platelet separation, expressed in terms of mean platelet volume, in terms of inlet hematocrit, which a utility function shown in Fig. 5 takes into account in generating a control variable governing plasma recirculation during processing.

The various aspects of the invention may be embodied in several forms without departing from its spirit or essential characteristics. The scope of the invention is defined in the appended claims, rather than in the specific description preceding them. All embodiments that fall within the meaning and range of equivalency of the claims are therefore intended to be embraced by the claims.

Description of the Preferred Embodiments

Fig. 1 shows in diagrammatic form an on line blood processing system 10 for carrying out an automated platelet collection procedure. The system 10 in many respects typifies a conventional two needle blood collection network, although a convention single needle network could also be used. The system 10 includes a processing controller 18 embodying the features of the invention.

I. The Separation System

The system 10 includes an arrangement of durable hardware elements, whose operation is governed by the processing controller 18. The hardware elements include a centrifuge 12, in which whole blood (WB) is separated into its various therapeutic components, like platelets, plasma, and red blood cells (RBC). The hardware elements will also include various pumps, which are typically peristaltic (designated P1 to P4); and various in line clamps and valves (designated V1 to V3). Of course, other types of hardware elements may
typically be present, which Fig. 1 does not show, like solenoids, pressure monitors, and the like.

The system 10 typically also includes some form of a disposable fluid processing assembly 14 used in association with the hardware elements.

In the illustrated blood processing system 10, the assembly 14 includes a two stage processing chamber 16. In use, the centrifuge 12 rotates the processing chamber 16 to centrifugally separate blood components. A representative centrifuge that can be used is shown in Williamson et al U.S. Patent No. 5,360,542.

The construction of the two stage processing chamber 16 can vary. For example, it can take the form of double bags, like the processing chambers shown in Cullis et al. U.S. Patent No. 4,146,172. Alternatively, the processing chamber 16 can take the form of an elongated two stage integral bag, like that shown in Brown U.S. Patent No. 5,370,802.

In the illustrated blood processing system 10, the processing assembly 14 also includes an array of flexible tubing that forms a fluid circuit. The fluid circuit conveys liquids to and from the processing chamber 16. The pumps P1-P4 and the valves V1-V3 engage the tubing to govern the fluid flow in prescribed ways. The fluid circuit further includes a number of containers (designated C1 to C3) to dispense and receive liquids during processing.

The controller 18 governs the operation of the various hardware elements to carry out one or more processing tasks using the assembly 14. The controller 18 also performs real time evaluation of
processing conditions and outputs information to aid
the operator in maximizing the separation and
collection of blood components. The invention
specifically concerns important attributes of the
controller 18.

The system 10 can be configured to accom-
plish diverse types of blood separation processes.
Fig. 1 shows the system 10 configured to carry out
an automated two needle platelet collection proce-
dure.

In a collection mode, a first tubing branch
20 and the whole blood inlet pump P2 direct WB from
a draw needle 22 into the first stage 24 of the
processing chamber 16. Meanwhile, an auxiliary
tubing branch 26 meters anticoagulant from the
container C1 to the WB flow through the antico-
agulant pump P1. While the type of anticoagulant can
vary, the illustrated embodiment uses ACDA, which is
a commonly used anticoagulant for pheresis.

The container C2 holds saline solution.
Another auxiliary tubing branch 28 conveys the
saline into the first tubing branch 20, via the in-
line valve V1, for use in priming and purging air
from the system 10 before processing begins. Saline
solution is also introduced again after processing
ends to flush residual components from the assembly
14 for return to the donor.

Anticoagulated WB enters and fills the
first stage 24 of the processing chamber 24. There,
centrifugal forces generated during rotation of the
centrifuge 12 separate WB into red blood cells (RBC)
and platelet-rich plasma (PRP).

The PRP pump P4 operates to draw PRP from
the first stage 24 of the processing chamber 16 into
a second tubing branch 30 for transport to the
second stage 32 of the processing chamber 16. There, the PRP is separated into platelet concentrate (PC) and platelet-poor plasma (PPP).

Optionally, the PRP can be conveyed through a filter F to remove leukocytes before separation in the second stage 32. The filter F can employ filter media containing fibers of the type disclosed in Nishimura et al U.S. Patent No. 4,936,998. Filter media containing these fibers are commercially sold by Asahi Medical Company in filters under the trade name SEPACELL.

The system 10 includes a recirculation tubing branch 34 and an associated recirculation pump P3. The processing controller 18 operates the pump P3 to divert a portion of the PRP exiting the first stage 24 of the processing chamber 16 for remixing with the WB entering the first stage 24 of the processing chamber 16. The recirculation of PRP establishes desired conditions in the entry region of the first stage 24 to provide maximal separation of RBC and PRP.

As WB is drawn into the first chamber stage 24 for separation, the illustrated two needle system simultaneously returns RBC from the first chamber stage 24, along with a portion of the PPP from the second chamber stage 32, to the donor through a return needle 36 through tubing branches 38 and 40 and in line valve V2.

The system 10 also collects PC (resuspended in a volume of PPP) in some of the containers C3 through tubing branches 38 and 42 and in line valve V3 for storage and beneficial use. Preferable, the container(s) C3 intended to store the PC are made of materials that, when compared to DEHP-plasticized
polyvinyl chloride materials, have greater gas permeability that is beneficial for platelet storage. For example, polyolefin material (as disclosed in Gajewski et al U.S. Patent 4,140,162), or a polyvinyl chloride material plasticized with tri-2-ethylhexyl trimellitate (TEHTM) can be used.

The system 10 can also collect PPP in some of the containers C3 through the same fluid path. The continuous retention of PPP serves multiple purposes, both during and after the component separation process.

The retention of PPP serves a therapeutic purpose during processing. PPP contains most of the anticoagulant that is metered into WB during the component separation process. By retaining a portion of PPP instead of returning it all to the donor, the overall volume of anticoagulant received by the donor during processing is reduced. This reduction is particularly significant when large blood volumes are processed. The retention of PPP during processing also keeps the donor's circulating platelet count higher and more uniform during processing.

The system 10 can also derive processing benefits from the retained PPP.

The system 10 can, in an alternative recirculation mode, recirculate a portion of the retained PPP, instead of PRP, for mixing with WB entering the first compartment 24. Or, should WB flow be temporarily halted during processing, the system 10 can draw upon the retained volume of PPP as an anticoagulated "keep-open" fluid to keep fluid lines patent. In addition, at the end of the separation process, the system 10 draws upon the retained volume of PPP as a "rinse-back" fluid, to
resuspend and purge RBC from the first stage compartment 24 for return to the donor through the return branch 40. After the separation process, the system 10 also operates in a resuspension mode to draw upon a portion of the retained PPP to resuspend PC in the second compartment 24 for transfer and storage in the collection container(s) C3.

II. The System Controller

The controller 18 carries out the overall process control and monitoring functions for the system 10 as just described.

In the illustrated and preferred embodiment (see Fig. 2), the controller comprises a main processing unit (MPU) 44. In the preferred embodiment, the MPU 44 comprises a type 68030 microprocessor made by Motorola Corporation, although other types of conventional microprocessors can be used.

In the preferred embodiment, the MPU 44 employs conventional real time multi-tasking to allocate MPU cycles to processing tasks. A periodic timer interrupt (for example, every 5 milliseconds) preempts the executing task and schedules another that is in a ready state for execution. If a reschedule is requested, the highest priority task in the ready state is scheduled. Otherwise, the next task on the list in the ready state is schedule.

A. Functional Hardware Control

The MPU 44 includes an application control manager 46. The application control manager 46 administers the activation of a library 48 of control applications (designated A1 to A3). Each control application A1-A3 prescribes procedures for carrying out given functional tasks using the system
hardware (e.g., the centrifuge 12, the pumps P1-P4, and the valves V1-V3) in a predetermined way. In the illustrated and preferred embodiment, the applications A1-A3 reside as process software in EPROM's in the MPU 44.

The number of applications A1-A3 can vary. In the illustrated and preferred embodiment, the library 48 includes at least one clinical procedure application A1. The procedure application A1 contains the steps to carry out one prescribed clinical processing procedure. For the sake of example in the illustrated embodiment, the library 48 includes a procedure application A1 for carrying out the dual needle platelet collection process, as already generally described in connection with Fig. 1. Of course, additional procedure applications can be, and typically will be, included. For example, the library 48 can include a procedure application for carrying out a conventional single needle platelet collection process.

In the illustrated and preferred embodiment, the library 48 also includes a system optimization application A2. The system optimization application A2 contains interrelated, specialized utility functions that process information based upon real time processing conditions and empirical estimations to derive information and control variables that optimize system performance. Further details of the optimization application A2 will be described later.

The library 48 also includes a main menu application A3, which coordinates the selection of the various applications A1-A3 by the operator, as will also be described in greater detail later.

Of course, additional non-clinical
procedure applications can be, and typically will be, included. For example, the library 48 can include a configuration application, which contains the procedures for allowing the operator to configure the default operating parameters of the system 10. As a further example, the library 48 can include a diagnostic application, which contains the procedures aiding service personnel in diagnosing and troubleshooting the functional integrity of the system, and a system restart application, which performs a full restart of the system, should the system become unable to manage or recover from an error condition.

An instrument manager 50 also resides as process software in EPROM's in the MPU 44. The instrument manager 50 communicates with the application control manager 46. The instrument manager 50 also communicates with low level peripheral controllers 52 for the pumps, solenoids, valves, and other functional hardware of the system.

As Fig. 2 shows, the application control manager 46 sends specified function commands to the instrument manager 50, as called up by the activated application A1-A3. The instrument manager 50 identifies the peripheral controller or controllers 52 for performing the function and compiles hardware-specific commands. The peripheral controllers 52 communicate directly with the hardware to implement the hardware-specific commands, causing the hardware to operate in a specified way. A communication manager 54 manages low-level protocol and communications between the instrument manager 50 and the peripheral controllers 52.

As Fig. 2 also shows, the instrument manager 50 also conveys back to the application
control manager 46 status data about the operational and functional conditions of the processing procedure. The status data is expressed in terms of, for example, fluid flow rates, sensed pressures, and fluid volumes measured.

The application control manager 46 transmits selected status data for display to the operator. The application control manager 46 transmits operational and functional conditions to the procedure application A1 and the performance monitoring application A2.

B. User Interface Control

In the illustrated embodiment, the MPU 44 also includes an interactive user interface 58. The interface 58 allows the operator to view and comprehend information regarding the operation of the system 10. The interface 58 also allows the operator to select applications residing in the application control manager 46, as well as to change certain functions and performance criteria of the system 10.

The interface 58 includes an interface screen 60 and, preferably, an audio device 62. The interface screen 60 displays information for viewing by the operator in alpha-numeric format and as graphical images. The audio device 62 provides audible prompts either to gain the operator’s attention or to acknowledge operator actions.

In the illustrated and preferred embodiment, the interface screen 60 also serves as an input device. It receives input from the operator by conventional touch activation. Alternatively or in combination with touch activation, a mouse or keyboard could be used as input devices.

An interface controller 64 communicates
with the interface screen 60 and audio device 62. The interface controller 64, in turn, communicates with an interface manager 66, which in turn communicates with the application control manager 46. The interface controller 64 and the interface manager 66 reside as process software in EPROM's in the MPU 44.

Further details of the interface 58 are disclosed in copending application Serial No. xxx.

C. The System Optimization Application

In the illustrated embodiment (as Fig. 3 shows), the system optimization application A2 contains six specialized yet interrelated utility functions, designated F1 to F6. Of course, the number and type of utility functions can vary.

In the illustrated embodiment, a utility function F1 derives the yield of the system 10 for the particular cellular component targeted for collection. For the platelet collection procedure application A1, the utility function F1 ascertains both the instantaneous physical condition of the system 10 in terms of its separation efficiencies and the instantaneous physiological condition of the donor in terms of the number of circulating platelets available for collection. From these, the utility function F1 derive the instantaneous yield of platelets continuously over the processing period.

Yet another utility function F2 relies upon the calculated platelet yield and other processing conditions to generate selected informational status values and parameters. These values and parameters are displayed on the interface 58 to aid the operator in establishing and maintaining optimal
performance conditions. The status values and parameters derived by the utility function F2 can vary. For example, in the illustrated embodiment, the utility function F2 reports remaining volumes to be processed, remaining processing times, and the component collection volumes and rates.

Another utility function F3 calculates and recommends, based upon the platelet yield derived by the utility function F1, the optimal storage parameters for the platelets in terms of the number of storage containers and the volume amount of PPP storage media to use.

Other utility functions generate control variables based upon ongoing processing conditions for use by the applications control manager 46 to establish and maintain optimal processing conditions. For example, one utility function F4 generates control variables to optimize platelet separation conditions in the first stage 24. Another utility function F5 generates control variables to control the rate at which citrate anticoagulant is returned with the PPP to the donor to avoid potential citrate toxicity reactions.

Yet another utility function F6 derives an estimated procedure time, which predicts the collection time before the donor is connected.

Further details of these utility functions F1 to F6 will now be described in greater detail.

III. Deriving Platelet Yield

The utility function F1 (see Fig. 4) makes continuous calculations of the platelet separation efficiency \( \eta_{pt} \) of the system 10. The utility function F1 treats the platelet separation efficiency \( \eta_{pt} \) as being the same as the ratio of plasma volume separated from the donor’s whole blood
relative to the total plasma volume available in the whole blood. The utility function $F_1$ thereby assumes that every platelet in the plasma volume separated from the donor’s whole blood will be harvested.

The donor’s hematocrit changes due to anticoagulant dilution and plasma depletion effects during processing, so the separation efficiency $n_{plt}$ does not remain at a constant value, but changes throughout the procedure. The utility function $F_1$ contends with these process-dependent changes by monitoring yields incrementally. These yields, called incremental cleared volumes ($\Delta$ClrVol), are calculated by multiplying the current separation efficiency $n_{plt}$ by the current incremental volume of donor whole blood, diluted with anticoagulant, being processed, as follows:

$$\Delta\text{ClrVol} = ACDil \times n_{plt} \times \Delta\text{Vol}_{proc}$$

where:

$\Delta\text{Vol}_{proc}$ is the incremental whole blood volume being processed, and

ACDil is an anticoagulant dilution factor for the incremental whole blood volume, computed as follows:

$$ACDil = \frac{AC}{AC + 1}$$

where:

AC is the selected ratio of whole blood volume to anticoagulant volume (for example 10:1 or “10”). AC may comprise a fixed value during the processing period. Alternatively, AC may be varied in a staged fashion according to prescribed criteria
during the processing period.

For example, AC can be set at the outset of processing at a lesser ratio for a set initial period of time, and then increased in steps after subsequent time periods; for example, AC can be set at 6:1 for the first minute of processing, then raised to 8:1 for the next 2.5 to 3 minutes; and finally raised to the processing level of 10:1.

The introduction of anticoagulant can also be staged by monitoring the inlet pressure of PRP entering the second processing stage 32. For example, AC can be set at 6:1 until the initial pressure (e.g., at 500 mmHg) falls to a set threshold level (e.g., 200 mmHg to 300 mmHg). AC can then be raised in steps up to the processing level of 10:1, while monitoring the pressure to assure it remains at the desired level.

The utility function F1 also makes continuous estimates of the donor's current circulating platelet count ($\text{Plt}_{\text{Cir}}$), expressed in terms of 1000 platelets per microliter (µl) of plasma volume (or k/µl). Like $n_{\text{Plt}}$, $\text{Plt}_{\text{Cir}}$ will change during processing due to the effects of dilution and depletion. The utility function F1 incrementally monitors the platelet yield in increments, too, by multiplying each incremental cleared plasma volume $\Delta \text{ClrVol}$ (based upon an instantaneous calculation of $n_{\text{Plt}}$) by an instantaneous estimation of the circulating platelet count $\text{Plt}_{\text{Cir}}$. The product is an incremental platelet yield ($\Delta \text{Yld}$), typically expressed as $e^n$ platelets, where $e = .5 \times 10^{11}$ platelets ($e^{11} = .5 \times 10^{11}$ platelets).

At any given time, the sum of the incremental platelet yields $\Delta \text{Yld}$ constitutes the current platelet yield $\text{Yld}_{\text{Current}}$, which can also be
expressed as follows:

\[
Yld_{\text{Current}} = Yld_{\text{Old}} + \frac{\Delta ClrVol \times Plt_{\text{Current}}}{100,000}
\]

where:

- \( Yld_{\text{Old}} \) is the last calculated \( Yld_{\text{Current}} \), and

\[
\Delta Yld = \frac{\Delta ClrVol \times Plt_{\text{Current}}}{100,000}
\]

where:

- \( Plt_{\text{Current}} \) is the current (instantaneous) estimate of the circulating platelet count of the donor.

\( \Delta Yld \) is divided by 100,000 in Eq (4) to balance units.

The following provides further details in the derivation of the above-described processing variables by the utility function \( F1 \).

A. Deriving Overall Separation Efficiency \( \eta_{\text{Plt}} \)

The overall system efficiency \( \eta_{\text{Plt}} \) is the product of the individual efficiencies of the parts of the system, as expressed as follows:

\[
\eta_{\text{Plt}} = \eta_{\text{1stSep}} \times \eta_{\text{2ndSep}} \times \eta_{\text{Anc}}
\]

where:

- \( \eta_{\text{1stSep}} \) is the efficiency of the separation of PRP from WB in the first separation stage.
- \( \eta_{\text{2ndSep}} \) is the efficiency of separation PC from PRP in the second separation stage.
- \( \eta_{\text{Anc}} \) is the product of the efficiencies of other ancillary processing steps in the system.
1. First Stage Separation Efficiency \( n_{1stSep} \)

The utility function F1 (see Fig. 4) derives \( n_{1stSep} \) continuously over the course of a procedure based upon measured and empirical processing values, using the following expression:

\[
\eta_{sep} = \frac{Q_p}{(1-H_b)Q_b}
\]

where:

- \( Q_b \) is the measured whole blood flow rate (in ml/min).
- \( Q_p \) is the measured PRP flow rate (in ml/min).
- \( H_b \) is the apparent hematocrit of the anticoagulated whole blood entering the first stage separation compartment. \( H_b \) is a value derived by the utility based upon sensed flow conditions and theoretical considerations. The utility function F1 therefore requires no on-line hematocrit sensor to measure actual WB hematocrit.

The utility function F1 derives \( H_b \) based upon the following relationship:

\[
H_b = \frac{H_{rbc}(Q_p - Q_p)}{Q_b}
\]

where:

- \( H_{rbc} \) is the apparent hematocrit of the RBC bed within the first stage separation chamber, based upon sensed operating conditions and the physical dimensions of the first stage separation chamber. As with \( H_b \), the utility function F1 requires no physical sensor to determine \( H_{rbc} \), which is derived
by the utility function according to the following expression:

$$H_{rbc} = 1 - \left( \frac{\beta}{gA\kappa S_y} \right)^{\frac{1}{k+1}}$$

where:

$q_b$ is inlet blood flow rate (cm$^3$/sec), which is a known quantity which, when converted to ml/min, corresponds with $Q_p$ in Eq (6).

$q_p$ is measured PRP flow rate (in cm$^3$/sec), which is a known quantity which, when converted to ml/min corresponds with $Q_p$ in Eq (6).

$\beta$ is a shear rate dependent term, and $S_y$ is the red blood cell sedimentation coefficient (sec).

Based upon empirical data, Eq (8) assumes that $\beta/S_y=15.8 \times 10^6$ sec$^{-1}$.

$A$ is the area of the separation chamber (cm$^2$), which is a known dimension.

$g$ is the centrifugal acceleration (cm/sec$^2$), which is the radius of the first separation chamber (a known dimension) multiplied by the rate of rotation squared $\Omega^2$ (rad/sec$^2$) (another known quantity).

$k$ is a viscosity constant = 0.625, and $\kappa$ is a viscosity constant based upon $k$ and another viscosity constant $\alpha = 4.5$, where:

$$\kappa = \frac{k+2}{\alpha} \left( \frac{k+2}{k+1} \right)^{k+1} = 1.272$$

Eq (8) is derived from the relationships expressed in the following Eq (10):
Eq (10)

\[ H_{rbc}(1-H_{rbc})^{(k-1)} = \frac{\beta H_s Q_b}{gA A S_Y} \]

2. The Second Stage Separation Efficiency \( \eta_{2ndsep} \)

The utility function \( F_2 \) (see Fig. 4) also derives \( \eta_{2ndsep} \) continuously over the course of a procedure based upon an algorithm, derived from computer modeling, that calculates what fraction of log-normally distributed platelets will be collected in the second separation stage as a function of their size (mean platelet volume, or MPV), the flow rate \( Q_p \), area \( A \) of the separation stage, and centrifugal acceleration \( g \), which is the spin radius of the second stage multiplied by the rate of rotation squared \( n^2 \).

The algorithm can be expressed in terms of a function shown graphically in Fig. 8. The graph plots \( \eta_{2ndsep} \) in terms of a single dimensionless parameter \( gA \sqrt{S_p} / Q_p \),

where:

\[ S_p = 1.8 \times 10^{-9} \text{ MPV}^{2/3} \text{ (sec), and} \]

MPV is the mean platelet volume (femtoliters, fl, or cubic microns), which can be measured by conventional techniques from a sample of the donor's blood collected before processing. There can be variations in MPV due to use of different counters. The utility function therefore may include a look up table to standardize MPV for use by the function according to the type of counter used.
Alternatively, MPV can be estimated based upon a function derived from statistical evaluation of clinical platelet precount Plt_{PRE} data, which the utility function can use. The inventor believes, based upon his evaluation of such clinical data, that the MPV function can be expressed as:

\[ \text{MPV (fI)} \approx 11.5 - 0.009 \text{Plt}_{\text{PRE}} \text{ (k/\mu l)} \]

3. Ancillary Separation Efficiencies \( \eta_{\text{Anc}} \)

\( \eta_{\text{Anc}} \) takes into account the efficiency (in terms of platelet loss) of other portions of the processing system. \( \eta_{\text{Anc}} \) takes into account the efficiency of transporting platelets (in PRP) from the first stage chamber to the second stage chamber; the efficiency of transporting platelets (also in PRP) through the leukocyte removal filter; the efficiency of resuspension and transferral of platelets (in PC) from the second stage chamber after processing; and the efficiency of reprocessing previously processed blood in either a single needle or a double needle configuration.

The efficiencies of these ancillary process steps can be assessed based upon clinical data or estimated based upon computer modeling. Based upon these considerations, a predicted value for \( \eta_{\text{Anc}} \) can be assigned, which Eq (5) treats as constant over the course of a given procedure.

B. Deriving Donor Platelet Count (Plt_{circ})

The utility function Fl (see Fig. 4) relies upon a kinetic model to predict the donor's current circulating platelet count Plt_{circ} during processing. The model estimates the donor's blood volume, and then estimates the effects of dilution and depletion during processing, to derive Plt_{circ}, according to the
following relationships:

\[
\text{Eq (11)}
\]

\[
\text{Plt}_{\text{Circ}} = [(\text{Dilution}) \times \text{Plt}_{\text{pre}}] - (\text{Depletion})
\]

where:

\[
\text{Plt}_{\text{pre}}
\]

is the donor's circulating platelet count before processing begins (k/\muL), which can be measured by conventional techniques from a sample of whole blood taken from the donor before processing. There can be variations in \text{Plt}_{\text{pre}} due to use of different counters (see, e.g., Peoples et al., "A Multi-Site Study of Variables Affecting Platelet Counting for Blood Component Quality Control," Transfusion (Special Abstract Supplement, 47th Annual Meeting), v. 34, No. 10S, October 1994 Supplement). The utility function therefore may include a look up table to standardize all platelet counts (such as, \text{Plt}_{\text{pre}} and \text{Plt}_{\text{post}}, described later) for use by the function according to the type of counter used.

\text{Dilution} is a factor that reduces the donor’s preprocessing circulating platelet count \text{Plt}_{\text{pre}} due to increases in the donor’s apparent circulating blood volume caused by the priming volume of the system and the delivery of anticoagulant. \text{Dilution} also takes into account the continuous removal of fluid from the vascular space by the kidneys during the procedure.

\text{Depletion} is a factor that takes into account the depletion of the donor’s available circulating platelet pool by processing. \text{Depletion} also takes into account the counter mobilization of the spleen in restoring platelets into the circulating blood volume during processing.

1. Estimating \text{Dilution}
The utility function $F_1$ estimates the dilution factor based upon the following expression:

$$\text{Eq (12)}$$

$$\text{Dilution} = 1 - \frac{2 \cdot \text{ACD} - \text{PPP}}{3 \cdot \text{DonVol}}$$

where:

- $\text{Prime}$ is the priming volume of the system (ml).
- $\text{ACD}$ is the volume of anticoagulant used (current or end-point, depending upon the time the derivation is made)(ml).
- $\text{PPP}$ is the volume of PPP collected (current or goal) (ml).
- $\text{DonVol}$ (ml) is the donor's blood volume based upon models that take into account the donor's height, weight, and sex. These models are further simplified using empirical data to plot blood volume against donor weight linearized through regression to the following, more streamlined expression:

$$\text{Eq (13)}$$

$$\text{DonVol} = 1024 + 5.1 \cdot \text{Wgt}$$

where:

- $\text{Wgt}$ is the donor's weight (kg).

2. Estimating Depletion

The continuous collection of platelets depletes the available circulating platelet pool. A first order model predicts that the donor's platelet count is reduced by the platelet yield (Yld) (current or goal) divided by the donor's circulating blood volume (DonVol), expressed as follows:
Eq (14)

\[ \text{Depl} = \frac{100,000 \text{Yld}}{\text{DonVol}} \]

where:
Yld is the current instantaneous or goal platelet yield (K/\mu l). In Eq (14), Yld is multiplied by 100,000 to balance units.

Eq (14) does not take into account splenic mobilization of replacement platelets, which is called the splenic mobilization factor (or Spleen). Spleen indicates that donors with low platelets counts nevertheless have a large platelet reserve held in the spleen. During processing, as circulating platelets are withdrawn from the donor's blood, the spleen releases platelets it holds in reserve into the blood, thereby partially offsetting the drop in circulating platelets. The inventor has discovered that, even though platelet pre-accounts vary over a wide range among donors, the total available platelet volume remains remarkably constant among donors. An average apparent donor volume is 3.10 ± 0.25 ml of platelets per liter of blood. The coefficient of variation is 8.1%, only slightly higher than the coefficient of variation in hematocrit seen in normal donors.

The inventor has derived the mobilization factor Spleen from comparing actual measured depletion to Depl (Eq (14)), which is plotted and linearized as a function of Plt_{PRE}, thereby expressing Spleen as a function of Plt_{PRE}, or:

\[ \text{Spleen} = f(\text{Plt}_{\text{PRE}}) \]

This analysis derives a curve, which
estimates the Spleen function, expressed as follows:

\[ Spleen = a - b(Plt_{pre}) \]

where:
- \(a\) is the y-intercept of the curve, and
- \(b\) is the slope of the curve.

The analysis reveals that \(a \approx 2.25\), and \(b \approx 0.004\). Therefore, Spleen (which is restricted to a lower limit of 1) can be generalized as follows:

\[ \text{Eq (15)} \]
\[ Spleen = [2.25 - 0.004 Plt_{pre}] \times 1 \]

Based upon Eqs (14) and (15), the utility function derives Depletion as follows:

\[ \text{Eq (16)} \]
\[ \text{Depletion} = \frac{100,000 Yld}{Spleen \times DonVol} \]

The Spleen function can be used in other contexts. For example, it makes possible the accurate estimation of the number of platelets \(N_{Spleen}\) held in reserve by the spleen in a human body. By inputting a current precount of platelets in the body (\(Plt_{pre}\)), the splenic mobilization function (Spleen) can be derived. \(N_{Spleen}\) can be estimated where:

\[ N_{Spleen} = (Spleen - 1) \times Plt_{pre} \times DonVol \]

where:
- DonVol is blood volume in the body.

Likewise, the Spleen function makes possible the accurate estimation of the total number of platelets \(N_{PLT}\) in a human body, using the
following expression:

\[ N_{PLT} = Plt_{PRE} \times Spleen \times DonVol \]

where:

- **DonVol** is blood volume in the body.

C. Real Time Procedure Modifications

The operator will not always have a current platelet pre-count \( Plt_{PRE} \) for every donor at the beginning of the procedure. The utility function \( F1 \) allows the system to launch under default parameters, or values from a previous procedure. The utility function \( F1 \) allows the actual platelet pre-count \( Plt_{PRE} \), to be entered by the operator later during the procedure. The utility function \( F1 \) recalculates platelet yields determined under one set of conditions to reflect the newly entered values. The utility function \( F1 \) uses the current yield to calculate an effective cleared volume and then uses that volume to calculate the new current yield, preserving the platelet pre-count dependent nature of splenic mobilization.

The utility function \( F1 \) uses the current yield to calculate an effective cleared volume as

\[
ClrVol = 100,000 \times DonVol \times Yld_{current} \\
\left[ DonVol - \frac{ACD}{3} - \frac{PPP}{2} \right] \times Pre_{old} - \frac{50,000 \times Yld_{current}}{Spleen_{old}}
\]

follows:

- **ClrVol** is the cleared plasma volume.
- **DonVol** is the donor's circulating blood
volume, calculated according to Eq (13).

\[ Yld_{\text{current}} \text{ is the current platelet yield calculated according to Eq (3) based upon current processing conditions.} \]

Prime is the blood-side priming volume (ml).

\[ ACD \text{ is the volume of anticoagulant used (ml).} \]

\[ PPP \text{ is the volume of platelet-poor plasma collected (ml).} \]

\[ P_{\text{old}} \text{ is the donor's platelet count before processing entered before processing begun (k/\mu l).} \]

\[ Spleen_{\text{old}} \text{ is the splenic mobilization factor calculated using Eq (16) based upon } P_{\text{old}}. \]

The utility function \( F_1 \) uses \( ClrVol_\text{calculated using Eq (17) to calculate the new current yield as follows:} \]

\[ \text{Eq (18)} \]

\[ \frac{\text{DonVol} - \text{Prime} - ACD + \frac{PPP}{3} - \frac{ACD}{2}}{\text{DonVol} + \frac{ClrVol}{2 \times Spleen_{\text{new}}}} \times \frac{ClrVol \times P_{\text{new}}}{100,000} \]

where:

\[ P_{\text{new}} \text{ is the revised donor platelet pre-count entered during processing (k/\mu l).} \]

\[ Yld_{\text{new}} \text{ is the new platelet yield that takes into account the revised donor platelet pre-count } P_{\text{new}}. \]

\[ ClrVol \text{ is the cleared plasma volume, calculated according to Eq (17).} \]

\[ \text{DonVol is the donor's circulating blood volume, calculated according to Eq (13), same as in Eq (17).} \]

Prime is the blood-side priming volume
(ml), same as in Eq (17).

ACD is the volume of anticoagulant used (ml), same as in Eq (17).

PPP is the volume of platelet-poor plasma collected (ml), same as in Eq (17).

Spleen\textsubscript{New} is the splenic mobilization factor calculated using Eq (15) based upon Pre\textsubscript{New}.

IV. Deriving Other Processing Information

The utility function F2 (see Fig. 5) relies upon the calculation of Yld by the first utility function F1 to derive other informational values and parameters to aid the operator in determining the optimum operating conditions for the procedure. The follow processing values exemplify derivations that the utility function F2 can provide.

A. Remaining Volume to be Processed

The utility function F2 calculates the additional processed volume needed to achieve a desired platelet yield \( V_{b_{\text{rem}}} \) (in ml) by dividing the remaining yield to be collected by the expected average platelet count over the remainder of the procedure, with corrections to reflect the current operating efficiency \( n_{\text{pl}} \). The utility function F2 derives this value using the following expression:

\[
V_{b_{\text{rem}}} = \frac{200,000 \times (Yld_{\text{Goal}} - Yld_{\text{Current}})}{n_{\text{pl}} \times \text{ACDil} \times (\text{Plt}_{\text{Current}} + \text{Plt}_{\text{Post}})}
\]

where:

\( Yld_{\text{Goal}} \) is the desired platelet yield (k/μl),

\( V_{b_{\text{rem}}} \) is the additional processing volume (ml) needed to achieve \( Yld_{\text{Goal}} \).

\( Yld_{\text{Current}} \) is the current platelet yield (k/μl), calculated using Eq (3) based upon current
processing values. 

\( n_{\text{plt}} \) is the present (instantaneous) platelet collection efficiency, calculated using Eq (5) based upon current processing values.

ACDil is the anticoagulant dilution factor (Eq (2)).

\( \text{Plt}_{\text{current}} \) is the current (instantaneous) circulating donor platelet count, calculated using Eq (11) based upon current processing values.

\( \text{Plt}_{\text{post}} \) is the expected donor platelet count after processing, also calculated using Eq (11) based upon total processing values.

B. Remaining Procedure Time

The utility function F2 also calculates remaining collection time (\( t_{\text{rem}} \)) (in min) as follows:

\[
\text{Eq (20)}
\]

\[
t_{\text{rem}} = \frac{V_{\text{b,rem}}}{Q_b}
\]

where:

\( V_{\text{b,rem}} \) is the remaining volume to be processed, calculated using Eq (19) based upon current processing conditions.

\( Q_b \) is the whole blood flow rate, which is either set by the user or calculated as \( Q_{b,\text{opt}} \) using Eq (31), as will be described later.

C. Plasma Collection

The utility function F2 adds the various plasma collection requirements to derive the plasma collection volume (\( \text{PPP}_{\text{goal}} \)) (in ml) as follows:

\[
\text{Eq (21)}
\]

\[
\text{PPP}_{\text{goal}} = \text{PPP}_{\text{PC}} + \text{PPP}_{\text{Source}} + \text{PPP}_{\text{Reinfuse}} + \text{PPP}_{\text{Waste}} + \text{PPP}_{\text{ColICham}}
\]

where:

\( \text{PPP}_{\text{PC}} \) is the platelet-poor plasma volume.
selected for the PC product, which can have a
typical default value of 250 ml, or be calculated as
an optimal value Pltmed according to Eq (28), as will
be described later.

\[ PPP_{Source} \] is the platelet-poor plasma volume
selected for collection as source plasma.

\[ PPP_{Waste} \] is the platelet-poor plasma volume
selected to be held in reserve for various
processing purposes (Default = 30 ml).

\[ PPP_{CollCham} \] is the volume of the plasma
collection chamber (Default = 40 ml).

\[ PPP_{Reinfuse} \] is the platelet-poor plasma volume
that will be reinfusion during processing.

D. Plasma Collection Rate

The utility function F2 calculates the
plasma collection rate \( Q_{PPP} \) (in ml/min) as follows:

\[ Q_{PPP} = \frac{PPP_{Goal} - PPP_{Current}}{t_{rem}} \]

where:

\[ PPP_{Goal} \] is the desired platelet-poor plasma
collection volume (ml).

\[ PPP_{Current} \] is the current volume of platelet-
poor plasma collected (ml).

\[ t_{rem} \] is the time remaining in collection,
calculated using Eq (20) based upon current
processing conditions.

E. Total Anticipated AC Usage

The utility function F2 can also calculate
the total volume of anticoagulant expected to be
used during processing \( (ACD_{End}) \) (in ml) as follows:
Eq (23)

\[ ACD_{\text{end}} = ACD_{\text{current}} + \frac{Q_b \times t_{\text{rem}}}{1 + AC} \]

where:

ACD_{\text{current}} is the current volume of anticoagulant used (ml).

AC is the selected anticoagulant ratio, 

Q_b is the whole blood flow rate, which is either set by the user or calculated using Eq (31) as Q_{b,\text{opt}} based upon current processing conditions.

t_{\text{rem}} is the time remaining in collection, calculated using Eq (20) based upon current processing conditions.

V. Recommending Optimum Platelet Storage Parameters

The utility function F3 (see Fig. 6) relies upon the calculation of Yld by the utility function F1 to aid the operator in determining the optimum storage conditions for the platelets collected during processing.

The utility function F3 derives the optimum storage conditions to sustain the platelets during the expected storage period in terms of the number of preselected storage containers required for the platelets Plt_{seg} and the volume of plasma (PPP) Plt_{med} (in ml) to reside as a storage medium with the platelets.

The optimal storage conditions for platelets depends upon the volume being stored Plt_{vol}, expressed as follows:

Eq (24)

\[ Plt_{vol} = Yld \times MPV \]

where:
Yld is the number of platelets collected, and

MPV is the mean platelet volume. As Plt_{vol} increases, so too does the platelets’ demand for oxygen during the storage period. As Plt_{vol} increases, the platelets’ glucose consumption to support metabolism and the generation of carbon dioxide and lactate as a result of metabolism also increase. The physical characteristics of the storage containers in terms of surface area, thickness, and material are selected to provide a desired degree of gas permeability to allow oxygen to enter and carbon dioxide to escape the container during the storage period.

The plasma storage medium contains bicarbonate HCO₃⁻, which buffers the lactate generated by platelet metabolism, keeping the pH at a level to sustain platelet viability. As Plt_{vol} increases, the demand for the buffer effect of HCO₃⁻, and thus more plasma volume during storage, also increases.

A. Deriving Plt_{\text{Bag}}

The partial pressure of oxygen pO₂ (mmHg) of platelets stored within a storage container having a given permeation decreases in relation to the total platelet volume Plt_{vol} the container holds. Fig. 9 is a graph based upon test data showing the relationship between pO₂ measured after one day of storage for a storage container of given permeation. The storage container upon which Fig. 9 is based has a surface area of 54.458 in² and a capacity of 1000 ml. The storage container has a permeability to O₂ of 194 cc/100 in²/day, and a permeability to CO₂ 1282 cc/100 in²/day.

When the partial pressure pO₂ drops below 20
mmHg, platelets are observed to become anaerobic, and the volume of lactate byproduct increases significantly. Fig. 9 shows that the selected storage container can maintain $pO_2$ of 40 mmHg (well above the aerobic region) at $Plt_{\text{Vol}} \leq 4.0 \text{ ml}$. On this conservative basis, the 4.0 ml volume is selected as the target volume $Plt_{\text{Vol}}$ for this container. Target volumes $Plt_{\text{Vol}}$ for other containers can be determined using this same methodology.

The utility function $F3$ uses the target platelet volume $Plt_{\text{Vol}}$ to compute $Plt_{\text{Bag}}$ as follows:

$$BAG = \frac{Plt_{\text{Vol}}}{Plt_{\text{Vol}}.$$}

and:

$$Plt_{\text{Bag}} = 1 \text{ when } BAG \leq 1.0, \text{ otherwise}$$

$$Plt_{\text{Bag}} = \lfloor BAG + 1 \rfloor, \text{ where } \lfloor BAG + 1 \rfloor \text{ is}$$

the integer part of the quantity $BAG + 1$.

For example, given a donor MPV of 9.5 fl, and a Yld of $4 \times 10^{11}$ platelets ($Plt_{\text{Vol}} = 3.8 \text{ ml}$), and given $Plt_{\text{Vol}} = 4.0 \text{ ml}$, $BAG = 0.95$, and $Plt_{\text{Bag}} = 1$. If the donor MPV is 11.0 fl and the yield Yld and $Plt_{\text{Vol}}$ remain the same ($Plt_{\text{Vol}} = 4.4 \text{ ml}$), $BAG = 1.1$ and $Plt_{\text{Bag}} = 2$.

When $Plt_{\text{Bag}} > 1$, $Plt_{\text{Vol}}$ is divided equally among the number of containers called for.

B. Deriving $Plt_{\text{Med}}$

The amount of bicarbonate used each day is a function of the storage thrombocytocrit $Tct$ ($\%$), which can be expressed as follows:

$$Tct = \frac{Plt_{\text{Vol}}}{Plt_{\text{Med}}}.$$
The relationship between bicarbonate HCO₃⁻ consumption per day and Tct can be empirically determined for the selected storage container. Fig. 10 shows a graph showing this relationship for the same container that the graph in Fig. 9 is based upon. The y-axis in Fig. 10 shows the empirically measured consumption of bicarbonate per day (in Meq/L) based upon Tct for that container. The utility function F3 includes the data expressed in Fig. 10 in a look-up table.

The utility function F3 derives the anticipated decay of bicarbonate per day over the storage period ΔHCO₃⁻ as follows:

\[ \Delta HCO₃^- = \frac{Don_{HCO₃^-}}{Stor} \]

where:

Don_{HCO₃^-} is the measured bicarbonate level in the donor's blood (Meq/L), or alternatively, is the bicarbonate level for a typical donor, which is believed to be 19.0 Meq/L ± 1.3, and

Stor is the desired storage interval (in days, typically between 3 to 6 days).

Given ΔHCO₃⁻, the utility function F3 derives Tct from the look up table for selected storage container. For the storage container upon which Fig. 10 is based, a Tct of about 1.35 to 1.5% is believed to be conservatively appropriate in most instances for a six day storage interval.

Knowing Tct and Plt_{vol}, the utility function F3 computes Plt_{med} based upon Eq (25), as follows:
\[
\text{Eq (28)}
\]
\[
\text{Plt}_{\text{Med}} = \frac{\text{Plt}_{\text{Vol}}}{Tct} \times 100
\]

When \( \text{Plt}_{\text{Bag}} > 1 \), \( \text{Plt}_{\text{Med}} \) is divided equally among the number of containers called for. \( \text{PPP}_{\text{PC}} \) is set to \( \text{Plt}_{\text{Med}} \) in Eq (21).

VI. **Deriving Control Variables**

The utility functions F4 and F5 rely upon the above-described matrix of physical and physiological relationships to derive process control variables, which the application control manager 46 uses to optimize system performance. The follow control variables exemplify derivations that the utility functions F4 and F5 can provide for this purpose.

A. **Promoting High Platelet Separation Efficiencies By Recirculation**

A high mean platelet value MPV for collected platelets is desirable, as it denotes a high separation efficiency for the first separation stage and the system overall. Most platelets average about 8 to 10 femtoliters, as measured by the Sysmex K-1000 machine (the smallest of red blood cells begin at about 30 femtoliters). The remaining minority of the platelet population constitutes platelets that are physically larger. These larger platelets typically occupy over \( 15 \times 10^{-15} \) liter per platelet, and some are larger than 30 femtoliters.

These larger platelets settle upon the RBC interface in the first separation chamber quicker than most platelets. These larger platelets are most likely to become entrapped in the RBC interface.
and not enter the PRP for collection. Efficient separation of platelets in the first separation chamber lifts the larger platelets from the interface for collection in the PRP. This, in turn, results a greater population of larger platelets in the PRP, and therefore a higher MPV.

Fig. 11, derived from clinical data, shows that the efficiency of platelet separation, expressed in terms of MPV, is highly dependent upon the inlet hematocrit of WB entering the first stage processing chamber. This is especially true at hematocrits of 30% and below, where significant increases in separation efficiencies can be obtained.

Based upon this consideration, the utility function F4 sets a rate for recirculating PRP back to the inlet of the first separation stage \( Q_{\text{Recirc}} \) to achieve a desired inlet hematocrit \( H_i \) selected to achieve a high MPV. The utility function F4 selects \( H_i \) based upon the following red cell balance equation:

\[
Q_{\text{Recirc}} = \left( \frac{H_b}{H_i} - 1 \right) \times Q_b
\]

In a preferred implementation, \( H_i \) is no greater than about 40%, and, most preferably, is about 32%.

B. Citrate Infusion Rate

Citrate in the anticoagulant is rapidly metabolized by the body, thus allowing its continuous infusion in returned PPP during processing. However, at some level of citrate infusion, donors will experience citrate toxicity. These reactions vary in both strength and nature,
and different donors have different threshold levels. A nominal a-symptomatic citrate infusion rate (CIR), based upon empirical data, is believed to about 1.25 mg/kg/min. This is based upon empirical data that shows virtually all donors can tolerate apheresis comfortably at an anticoagulated blood flow rates of 45 ml/min with an anticoagulant (ACD-A anticoagulant) ratio of 10:1.

Taking into account that citrate does not enter the red cells, the amount given to the donor can be reduced by continuously collecting some fraction of the plasma throughout the procedure, which the system accomplishes. By doing so, the donor can be run at a higher flow rate than would be expected otherwise. The maximum a-symptomatic equivalent blood flow rate (EqQbCIR) (in ml/min) under these conditions is believed to be:

\[
\text{EqQb}_{\text{CIR}} = \frac{\text{CIR} \times (AC+1) \times Wgt}{\text{CitrateConc}}
\]

where:

- CIR is the selected nominal a-symptomatic citrate infusion rate, or 1.25 mg/kg/min.
- AC is the selected anticoagulant ratio, or 10:1.
- Wgt is the donor's weight (kg).
- CitrateConc is the citrate concentration in the selected anticoagulant, which is 21.4 mg/ml for ACD-A anticoagulant.

C. Optimum Anticoagulated Blood Flow

The remaining volume of plasma that will be returned to the donor is equal to the total amount available reduced by the amount still to be
collected. This ratio is used by the utility function F5 (see Fig. 5) to determine the maximum, or optimum, a-symptomatic blood flow rate \( Q_{b_{opt}} \) (in ml/min) that can be drawn from the donor, as follows:

\[
Q_{b_{opt}} = \frac{(1-H_b) \times V_{b_{rem}}}{(1-H_b) \times V_{b_{rem}} - (PPP_{Goal} - PPP_{Current})} \times EqQB_{CIR}.
\]

where:

- \( H_b \) is the anticoagulated hematocrit, calculated using Eq (7) based upon current processing conditions.
- \( V_{b_{rem}} \) is the remaining volume to be processed, calculated using Eq (19) based upon current processing conditions.
- \( EqQB_{CIR} \) is the citrate equivalent blood flow rate, calculated using Eq (30) based upon current processing conditions.
- \( PPP_{Goal} \) is the total plasma volume to be collected (ml).
- \( PPP_{Current} \) is the current plasma volume collected (ml).

**VII. Estimated Procedure Time**

The utility function F6 (see Fig. 7) derives an estimated procedure time \( t \) (in min), which predicts the collection time before the donor is connected. To derive the estimated procedure time \( t \), the utility function F6 requires the operator to input the desired yield \( Yld_{Goal} \) and desired plasma collection volume \( PPP_{Goal} \), and further requires the donor weight \( Wgt \), platelet pre-count \( Plt_{pre} \), and hematocrit \( H_b \) or a default estimate of it.

If the operator wants recommended platelet storage parameters, the utility function requires MPV as an
input.

The utility function F6 derives the estimated procedure time \( t \) as follows:

\[
Eq \ (32) \quad t = \frac{-b + \sqrt{b^2 - 4ac}}{2a}
\]

where:

\[
Eq \ (33) \quad a = \frac{H_{eq} - H_b}{(1 - H_b)} \cdot EqQb_{CIR}
\]

\[
Eq \ (34) \quad b = \frac{(H_{eq} - H_b - \lambda H_b EqQb_{CIR}) PPP}{(1 - H_b)^2} - H_{eq} PV
\]

\[
Eq \ (35) \quad c = \left[ PV - \frac{PPP}{(1 - H_b)^2} \right] \frac{\lambda H_b PPP}{(1 - H_b)}
\]

and where:

\( H_{eq} \) is a linearized expression of the RBC hematocrit \( H_{RBC} \), as follows:

\[
Eq \ (36) \quad H_{eq} = 0.9489 - \lambda H_b EqQb_{CIR}
\]

where:

\( H_b \) is the donor's anticoagulated hematocrit, actual or default estimation.

\( EqQb_{CIR} \) is the maximum a-symptomatic equivalent blood flow rate calculated according to Eq (30).

and
Eq (37)

\[ \lambda = \frac{61.463}{\Omega^2} \]

where:

\( \Omega \) is the rotation speed of the processing chamber (rpm).

and where:

PPP is the desired volume of plasma to be collected (ml).

PV is the partial processed volume, which is that volume that would need to be processed if the overall separation efficiency \( n_{\text{plt}} \) was 100%, derived as follows:

Eq (38)

\[ PV = \frac{ClrVol}{n_{\text{ANC}} \times n_{\text{ind sep}} \times ACD_{\text{Dil}}} \]

where:

ACD\(_{\text{Dil}}\) is the anticoagulant dilution factor (Eq (2)).

ClrVol is the cleared volume, derived as:

Eq (39)

\[ ClrVol = \frac{100,000 \times DonVol \times Yld}{[DonVol-Prime - \frac{ACD_{\text{Ext}}}{3} + \frac{PPP}{2} \times \text{Plt}_{\text{Prf}} - \frac{50,000 \times Yld}{\text{Spleen}}} \]

where:

Yld is the desired platelet yield.

DonVol is the donor’s blood volume = 1024 + 51Wgt (ml).

Prime is the blood side priming volume of the system (ml).

ACD\(_{\text{Ext}}\) is the estimated anticoagulant volume to be used (ml).
Plt$_{pre}$ is the donor's platelet count before processing, or a default estimation of it.

Spleen is the is the splenic mobilization factor calculated using Eq (16) based upon Plt$_{pre}$.

The function F6 also derives the volume of whole blood needed to be processed to obtain the desired Yld$_{goal}$. This processing volume, WBVol, is expressed as follows:

\[
WBVol = t \times EqQb_{CJR} \times \frac{PPP_{goal}}{(1 - H_b)} + WB_{RES}
\]

where:

- $t$ is the estimated procedure time derived according to Eq(32).
- $H_b$ is the donor's anticoagulated hematocrit, actual or default estimation.
- EqQb$_{CJR}$ is the maximum a-symptomatic equivalent blood flow rate calculated according to Eq (30).
- PPP$_{goal}$ is the desired plasma collection volume.
- WB$_{RES}$ is the residual volume of whole blood left in the system after processing, which is a known system variable and depends upon the priming volume of the system.

Various features of the inventions are set forth in the following claims.
What is claimed is:

1. A system for separating platelets from blood comprising:
   a separation device for separating blood into plasma and platelets;
   an inlet to the separation device to convey anticoagulated blood containing plasma
   and platelets from a donor into the separation device for separating into a plasma yield and
   a platelet yield; and
   a processing element coupled to the separation device including a first element that
   estimates, at least in part while separation occurs in the separation device, the total number
   of platelets $N_{PLT}$ available for collection from the donor by a method comprising the steps of:
   determining a preprocessing count of circulating platelets ($Plt_{PRE}$) in the
   donor;
   deriving a value reflecting spleen function ($Spleen$) where $Spleen = f(Plt_{PRE})$; and
   deriving $N_{PLT}$ where $N_{PLT} = Plt_{PRE} \times Spleen \times DonVol$
where:
   $DonVol$ is blood volume in the donor's body,
   the processing element further including an output to output $N_{PLT}$.

2. A system according to Claim 1 wherein a curve estimates the $Spleen$ function, expressed as follows:
   $$Spleen = a-b(Plt_{PRE})$$
where:
   $a$ is the $y$-intercept of the curve; and
   $b$ is the slope of the curve.

3. A system according to claim 2 wherein $a \approx 2.25$, and wherein $b \approx 0.004$.

4. A system according to any one of claims 1 to 3 wherein the processing element
   estimates, at least in part while separation occurs in the separation device, a count of
platelets ($Plt_{circ}$) available for collection from the donor by a method comprising the steps of:
estimating a dilution factor caused by addition of anticoagulant (Dilution); and
estimating a depletion factor (Depletion) caused by removal of available platelets
during blood processing, wherein:

\[
Plt_{circ} = [(Dilution) \times Plt_{pre}] - (Depletion)
\]

5. A system according to Claim 4 wherein Dilution is estimated as follows:

\[
Dilution = \frac{Prime + Kid - PPP}{DonVol}
\]

where:

- $Prime$ is a priming fluid volume (ml) of the separation device;
- PPP is a value reflecting volume of plasma yield that is not returned to the donor (ml);
- Kid is an empirically determined constant reflecting kidney function; and $DonVol$ (ml) is the total volume of donor blood.

6. A system according to Claim 5 wherein $DonVol$ is derived as:

\[
DonVol = 1024 + 51Wgt
\]

where:

- Wgt is the donor’s weight (kg).

7. A system according to Claim 4 wherein Depletion is estimated as follows:

\[
Depletion = \frac{100,000Yld}{Spleen \times DonVol}
\]

where:

- Yld is the derived yield of platelet ($k/\mu l$) at the time Depletion is estimated; $DonVol$ is the total volume of donor blood (ml); and
- $Spleen$ is a value reflecting spleen function.

8. A system according to Claim 4 wherein a curve estimates the $Spleen$ function as follows:
Spleen = a - b(Plt\textsubscript{PRE})

where:

a is the y-intercept of the curve;
b is the slope of the curve; and
Plt\textsubscript{PRE} is a count of the donor's circulating platelets.

9. A system according to Claim 4 wherein Spleen is expressed as follows:

\[ Spleen = [2.25-0.004 \text{ Plt}_{\text{PRE}}] \geq 1 \]

10. A method for estimating the total number of platelets \( N_{\text{PLT}} \) in a donor's body comprising the steps of:

- measuring a preprocessing count of circulating platelets in the body (Plt\textsubscript{PRE});
- estimating a value reflecting spleen function (Spleen) where Spleen = \( f(\text{Plt}_{\text{PRE}}) \);
- estimating \( N_{\text{PLT}} \) where \( N_{\text{PLT}} = \text{Plt}_{\text{PRE}} \times \text{Spleen} \times \text{DonVol} \)

where:

DonVol is a blood volume in the donor's body; and

generating an output based upon \( N_{\text{PLT}} \).

11. A method according to Claim 10 wherein a curve estimates the Spleen function, expressed as follows:

\[ Spleen = a - b(\text{Plt}_{\text{PRE}}). \]

12. A method according to Claim 11 wherein \( a \approx 2.25 \), and wherein \( b \approx 0.004 \).

13. A method according to any one of claims 10 to 12 further comprising the step of:

- estimating a count of platelets (Plt\textsubscript{Circ}) in the body by a method comprising the steps of:

- estimating a dilution factor caused by addition of anticoagulant (Dilution); and
- estimating a depletion factor (Depletion) caused by removal of available platelets during blood processing, wherein:

\[ \text{Plt}_{\text{Circ}} = [(\text{Dilution}) \times \text{Plt}_{\text{pre}}] - (\text{Depletion}) \]
14. A method according to Claim 13 wherein Dilution is estimated as follows:

\[
\text{Dilution} = 1 - \frac{\text{Prime} + \text{Kid} - \text{PPP}}{\text{DonVol}}
\]

where:

- **Prime** is a priming fluid volume (ml) of the separation device;
- **PPP** is a value reflecting volume of plasma yield that is not returned to the donor (ml);
- **Kid** is an empirically determined constant reflecting kidney function; and
- **DonVol(ml)** is the total volume of donor blood.

15. A method according to Claim 14 wherein DonVol is derived as:

\[
\text{DonVol} = 1024 + 51\text{Wgt}
\]

where:

- **Wgt** is the donor's weight (kg).

16. A method according to Claim 13 wherein Depletion is estimated as follows:

\[
\text{Depletion} = \frac{100,000\text{Yld}}{\text{Spleen} \times \text{DonVol}}
\]

where:

- **Yld** is the derived yield of platelets (k/μl) at the time Depletion is estimated;
- **DonVol** is the total volume of donor blood (ml); and
- **Spleen** is a value reflecting spleen function.

17. A method according to Claim 13 wherein a curve estimates the **Spleen** function as follows:

\[
\text{Spleen} = a - b(\text{Plt}_{\text{PRE}})
\]

where:

- **a** is the y-intercept of the curve;
- **b** is the slope of the curve; and
- **Plt_{PRE}** is the count of the donor's circulating platelets.
18. A method according to Claim 13 wherein Spleen is expressed as follows:

\[ Spleen = [2.25-0.004 \text{ Plt}_{\text{PRE}}] \geq 1 \]

19. A device that estimates the total number of platelets \( N_{\text{PLT}} \) in a human body comprising:

an input for receiving a preprocessing count of circulating platelets in the body \( \text{ (Plt}_{\text{PRE}} \) ; and \\

a processor coupled to the input including:

an element that derives a value reflecting spleen function \( (Spleen) \) where:

\[ Spleen = f(\text{Plt}_{\text{PRE}}) \]

and

an element that estimates \( N_{\text{PLT}} \) where:

\[ N_{\text{PLT}} = \text{Plt}_{\text{PRE}} \times Spleen \times \text{DonVol} \]

where:

Donvol is blood volume in the body; and \\
an output coupled to the processor to output \( N_{\text{PLT}} \).

20. A device according to claim 19

wherein a curve estimates the \( Spleen \) function, expressed as follows:

\[ Spleen = a - b(\text{Plt}_{\text{PRE}}) \]

where:

\( a \) is the \( y \)-intercept of the curve; and \\

\( b \) is the slope of the curve.

21. A device according to claim 20 wherein \( a \approx 2.25 \), and wherein \( b \approx 0.004 \).
