SUMMARY OF THE INVENTION

[0002] Described herein are compounds that modulate the activity of the neurotensin 1 receptor (NTR1). The neurotensin 1 receptor is a therapeutic target for the treatment of a variety of diseases or conditions. In some embodiments, the neurotensin 1 receptor is a therapeutic target for the treatment of diseases or conditions such as, but not limited to, neurological diseases or conditions, and cancer. In some embodiments, the compounds described herein are agonists of the neurotensin 1 receptor.

DETAILED DESCRIPTION OF THE INVENTION

[0025] Neurotensin is a 13 amino acid neuropeptide that is implicated in the regulation of luteinizing hormone and prolactin release and has significant interaction with the dopaminergic system. Neurotensin was first isolated from extracts of bovine hypothalamus based on its ability to cause a visible vasodilation in the exposed cutaneous regions of anesthetized rats. Neurotensin is distributed throughout the central nervous system, with highest levels in the hypothalamus, amygdala and nucleus accumbens. It induces a variety of effects, including: analgesia, hypothermia and increased locomotor activity. It is also involved in regulation of dopamine pathways. In the periphery, neurotensin is found in endocrine cells of the small intestine, where it leads to secretion and smooth muscle contraction

[0026] Neurotensin has been implicated in the modulation of dopamine signaling, and produces a spectrum of pharmacological effects resembling those of antipsychotic drugs, leading to the suggestion that neurotensin may be an endogenous neuroleptic. Neurotensin-deficient mice display defects in responses to several antipsychotic drugs consistent with the idea that neurotensin signaling is a key component underlying at least some antipsychotic drug actions. These mice exhibit modest defects in prepulse inhibition (PPI) of the startle reflex, a model that has been widely used to investigate antipsychotic drug action in animals. Antipsychotic drug administration augments PPI under certain conditions. Comparisons between normal and neurotensin-deficient mice revealed striking differences in the ability of different antipsychotic drugs to augment PPI. While the atypical antipsychotic drug clozapine augmented PPI normally in neurotensin-deficient mice, the antipsychotic haloperidol and the antipsychotic quetiapine were ineffective in these mice, in contrast to normal mice where these drugs significantly augmented PPI. These results suggest that certain antipsychotic drugs require neurotensin for at least some of their effects. Neurotensin-deficient mice also display defects in striatal activation following haloperidol, but not clozapine administration in comparison to normal wild type mice, indicating that striatal neurotensin is required for the full spectrum of neuronal responses to a subset of antipsychotic drugs.

[0027] Neurotensin is an endogenous neuropeptide involved in thermoregulation that can induce hypothermia and neuroprotection in experimental models of cerebral ischemia.

[0028] The neurotensin receptors are transmembrane receptors that bind the neurotransmitter neurotensin. Two of the receptors encoded by the NTSR1 and NTSR2 genes contain seven transmembrane helices and are G protein coupled. The third receptor has a single transmembrane domain and is encoded by the SORT1 gene.

[0029] Addiction is the continued repetition of a behavior despite adverse consequences, or a neurological impairment leading to such behaviors. Addictions can include, but are not limited to, drug abuse, exercise addiction, food addiction, sexual addiction, computer addiction and gambling. Classic

hallmarks of addiction include impaired control over substances or behavior, preoccupation with substance or behavior, continued use despite consequences, and denial. Habits and patterns associated with addiction are typically characterized by immediate gratification (short-term reward), coupled with delayed deleterious effects (long-term costs). Some drugs associated with addiction include alcohol, substituted amphetamines (e.g. methamphetamine), barbiturates, benzodiazepines (particularly alprazolam, temazepam, diazepam and clonazepam), cocaine, methaqualone, and opioids.

[0030] Neurotensin (NT) receptors are expressed on dopaminergic neurological pathways associated with reward, and the neurotensin receptor 1 (NTR1) is a therapeutic target for the treatment of methamphetamine abuse. In particular, peptide-based NTR1 agonists produce behaviors that are opposite to the psychostimulant effects observed with psychoactive drugs, such as but not limited to methamphetamine, such as hyperactivity, neurotoxicity, psychotic episodes, and cognitive deficits.

[0031] NTR1 is a G protein coupled receptor (GPCR). Two distinct, interdependent paradigms are associated with GPCR signaling. In addition to the well-defined signaling cascades involving heterotrimeric G proteins, recent advances in receptor pharmacology have identified the importance of β -arrestins in regulating alternative biochemical cascades that produce their own unique biological effects. For example, in a mouse model, Allen et al developed a series of β -arrestin-2 biased agonists for the D(2)R with antipsychotic properties, and most importantly, a reduced propensity to induce catalepsy like standard neuroleptic antagonists (Allen et al. Discovery of β -Arrestin-Biased Dopamine D2 Ligands for Probing Signal Transduction Pathways Essential for Antipsychotic Efficacy. *Proc. Natl. Acad. Sci. USA.* **2011**, *108*, 18488-18493; Rajagopal et al. Teaching old receptors new tricks: biasing seven-

transmembrane receptors. *Nat. Rev. Drug Discovery* **2010**, *9*, 373-386.). Studies with those biased compounds illustrate how ligand directed signaling bias, in this case favoring β -arrestin, can ameliorate undesirable biological outcomes. Downstream modulators of β -arrestin/GPCR signaling are less characterized than their G protein counterparts, and, due to their potential as targets for producing new medical therapies are the subjects of increasing numbers of investigations. Recognized β -arrestin partners include the proteins Src, ERK, and Jnk. Their agonist-induced interactions with β -arrestin are associated with clathrin-compartmentalized signaling and the accumulation of ligand activated β -arrestin/GPCR complexes in clathrin coated pits. The determination as to whether a GPCR ligand is biased towards or against β -arrestin may consequently be evaluated by following these biochemical processes.

[00196] Non-limiting examples of compounds of Formula (I), (II), (III), (IV), (V), (VI), (VII) or (VIII), include:

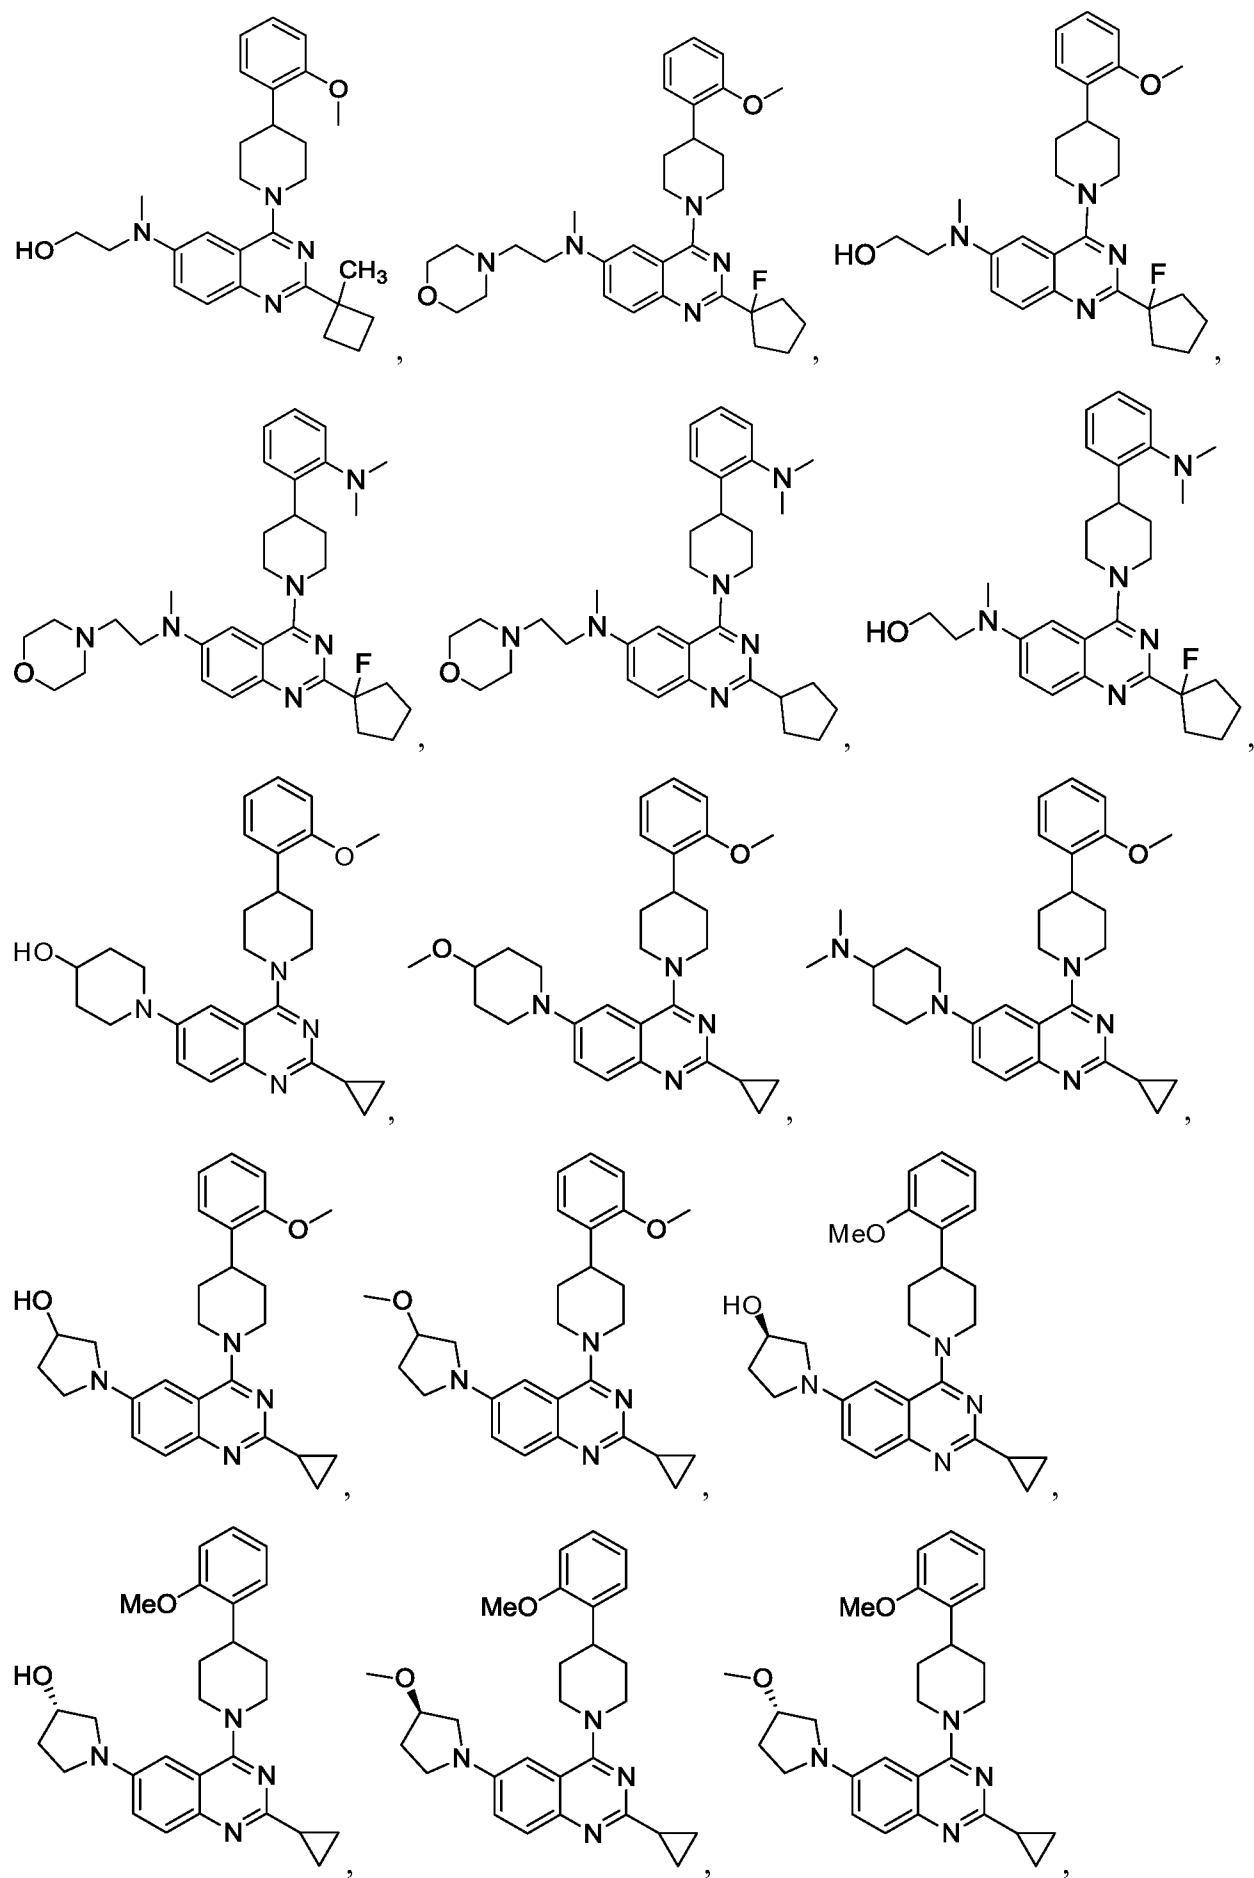

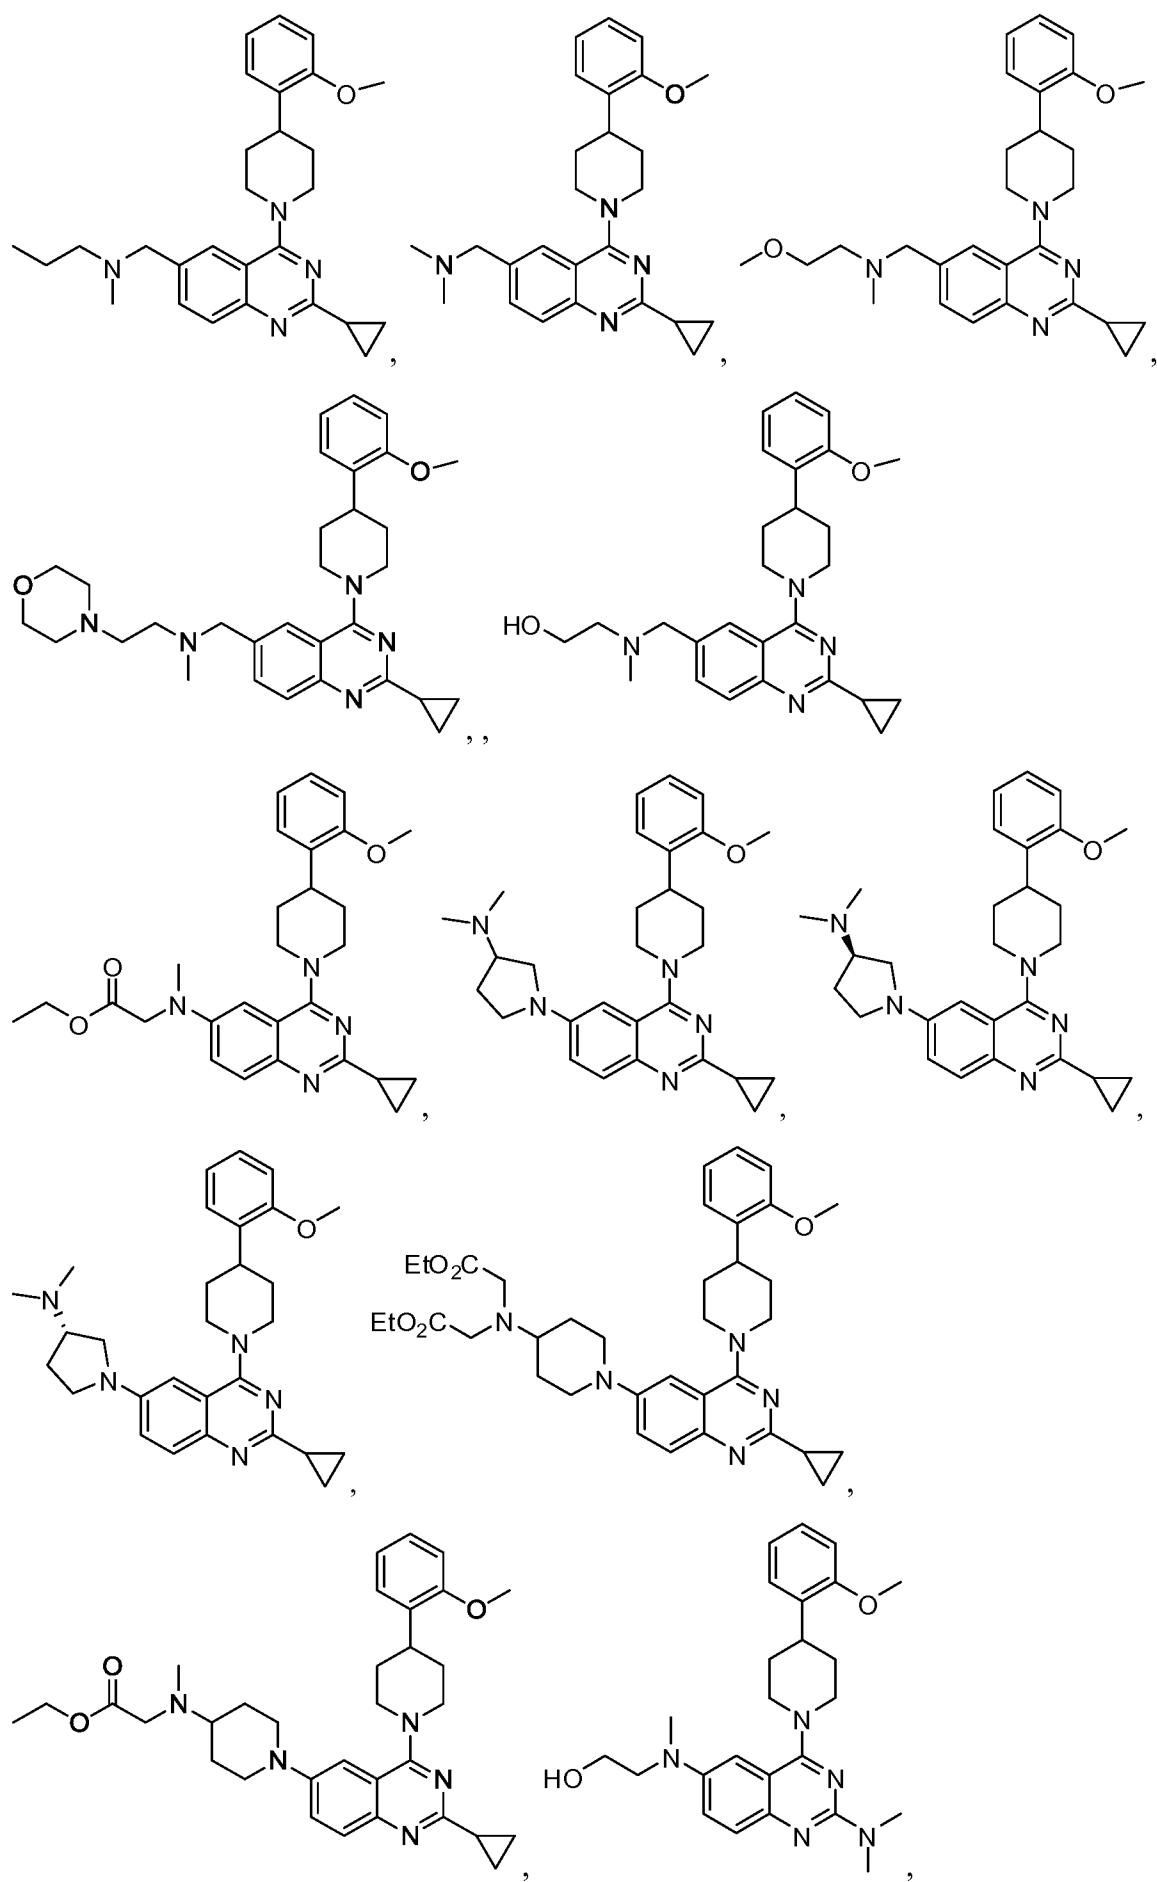

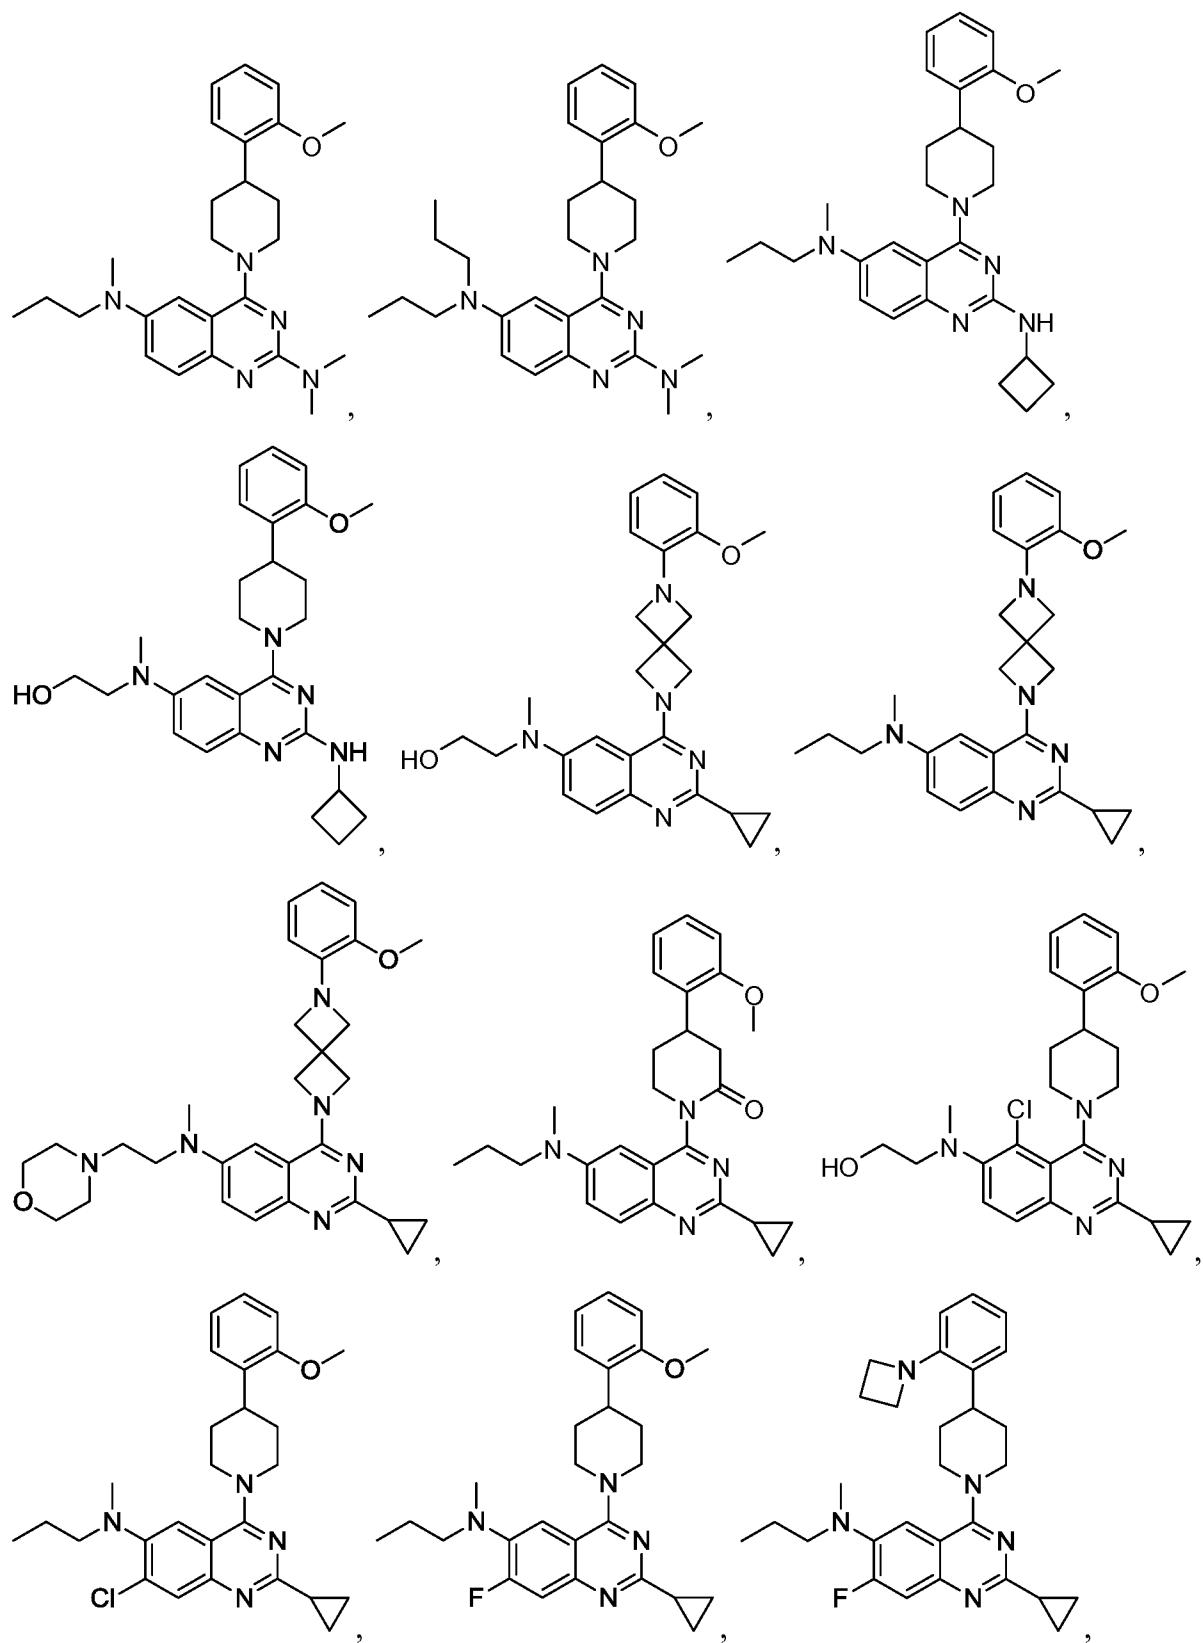

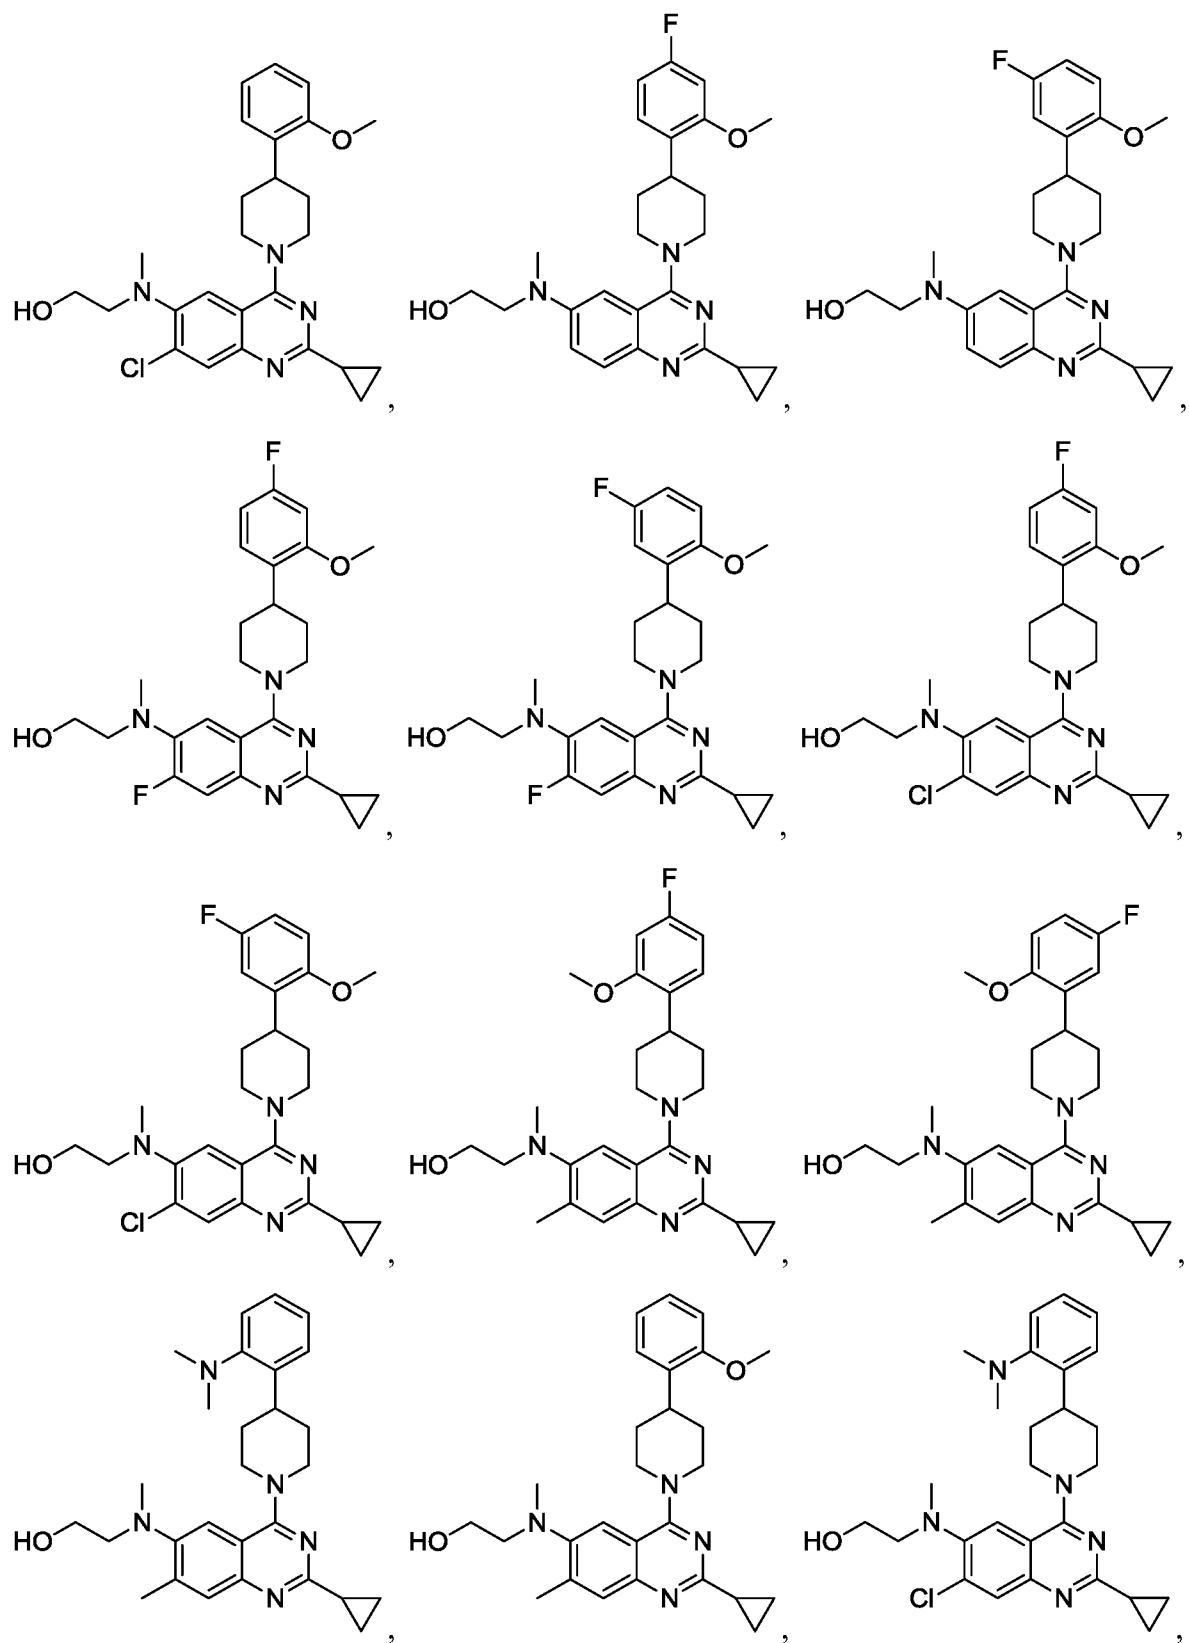

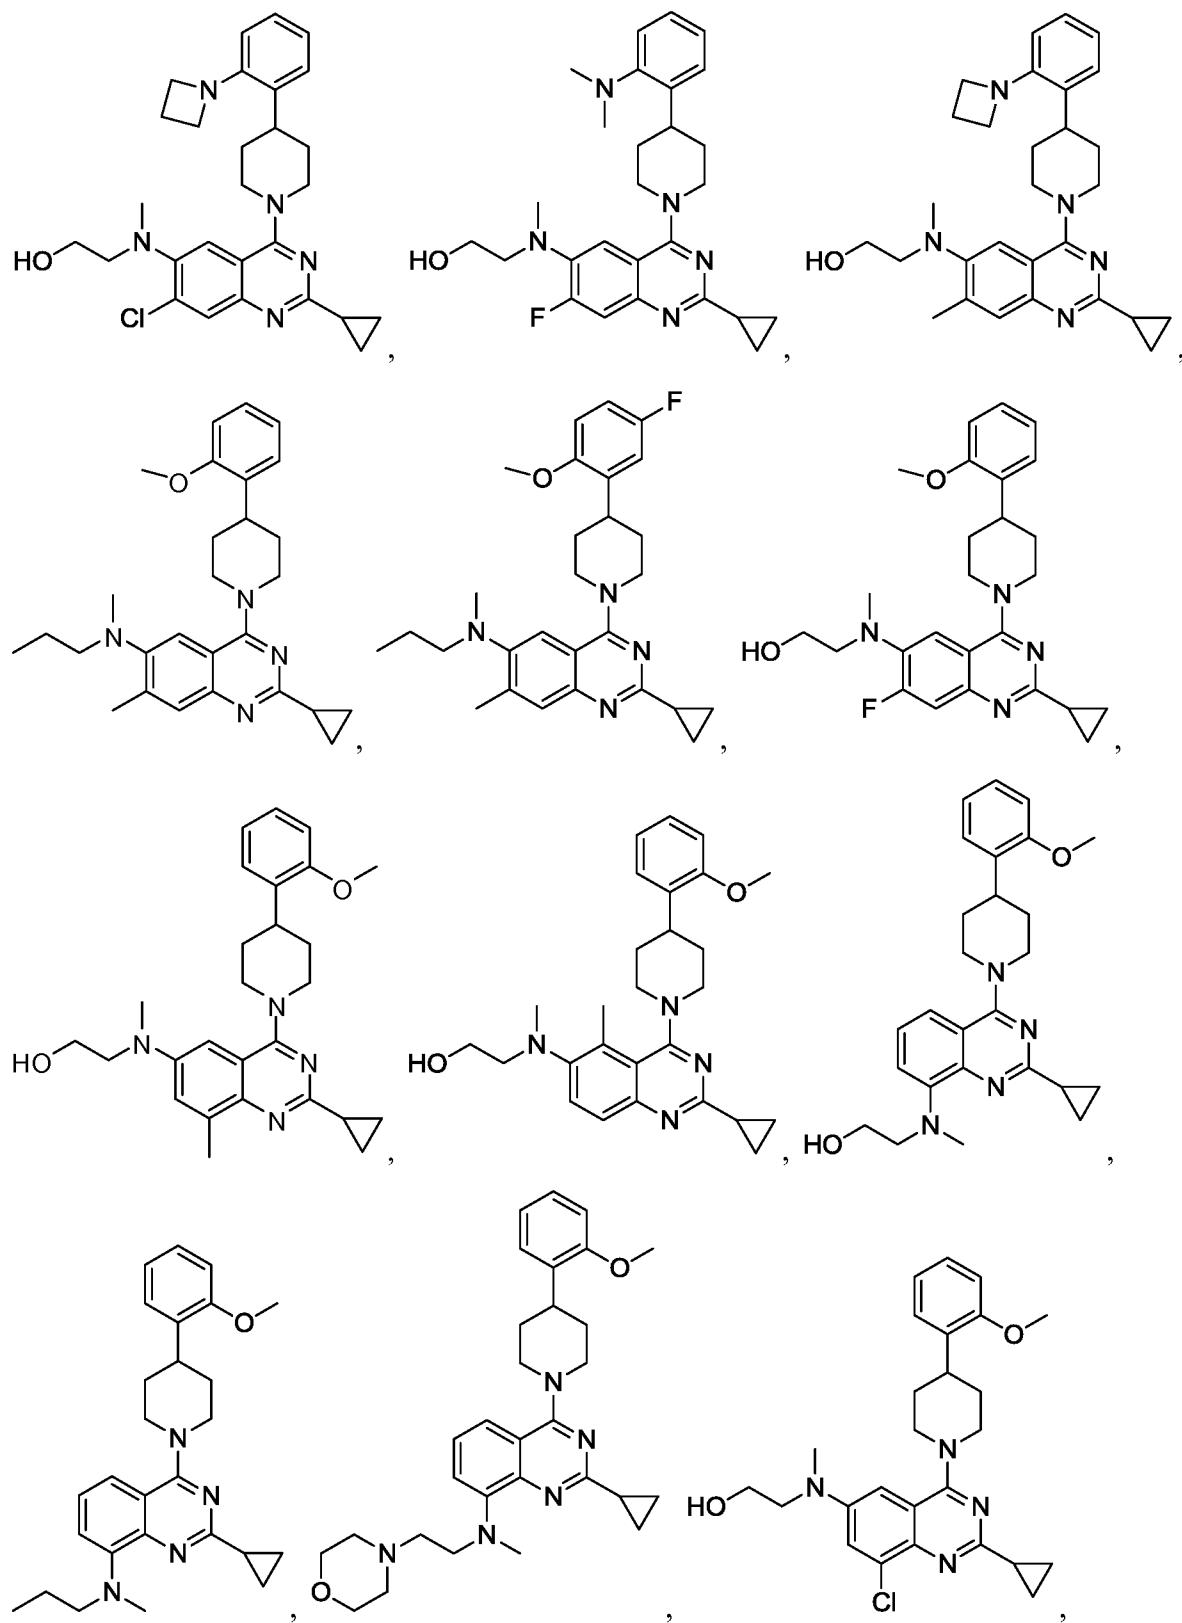

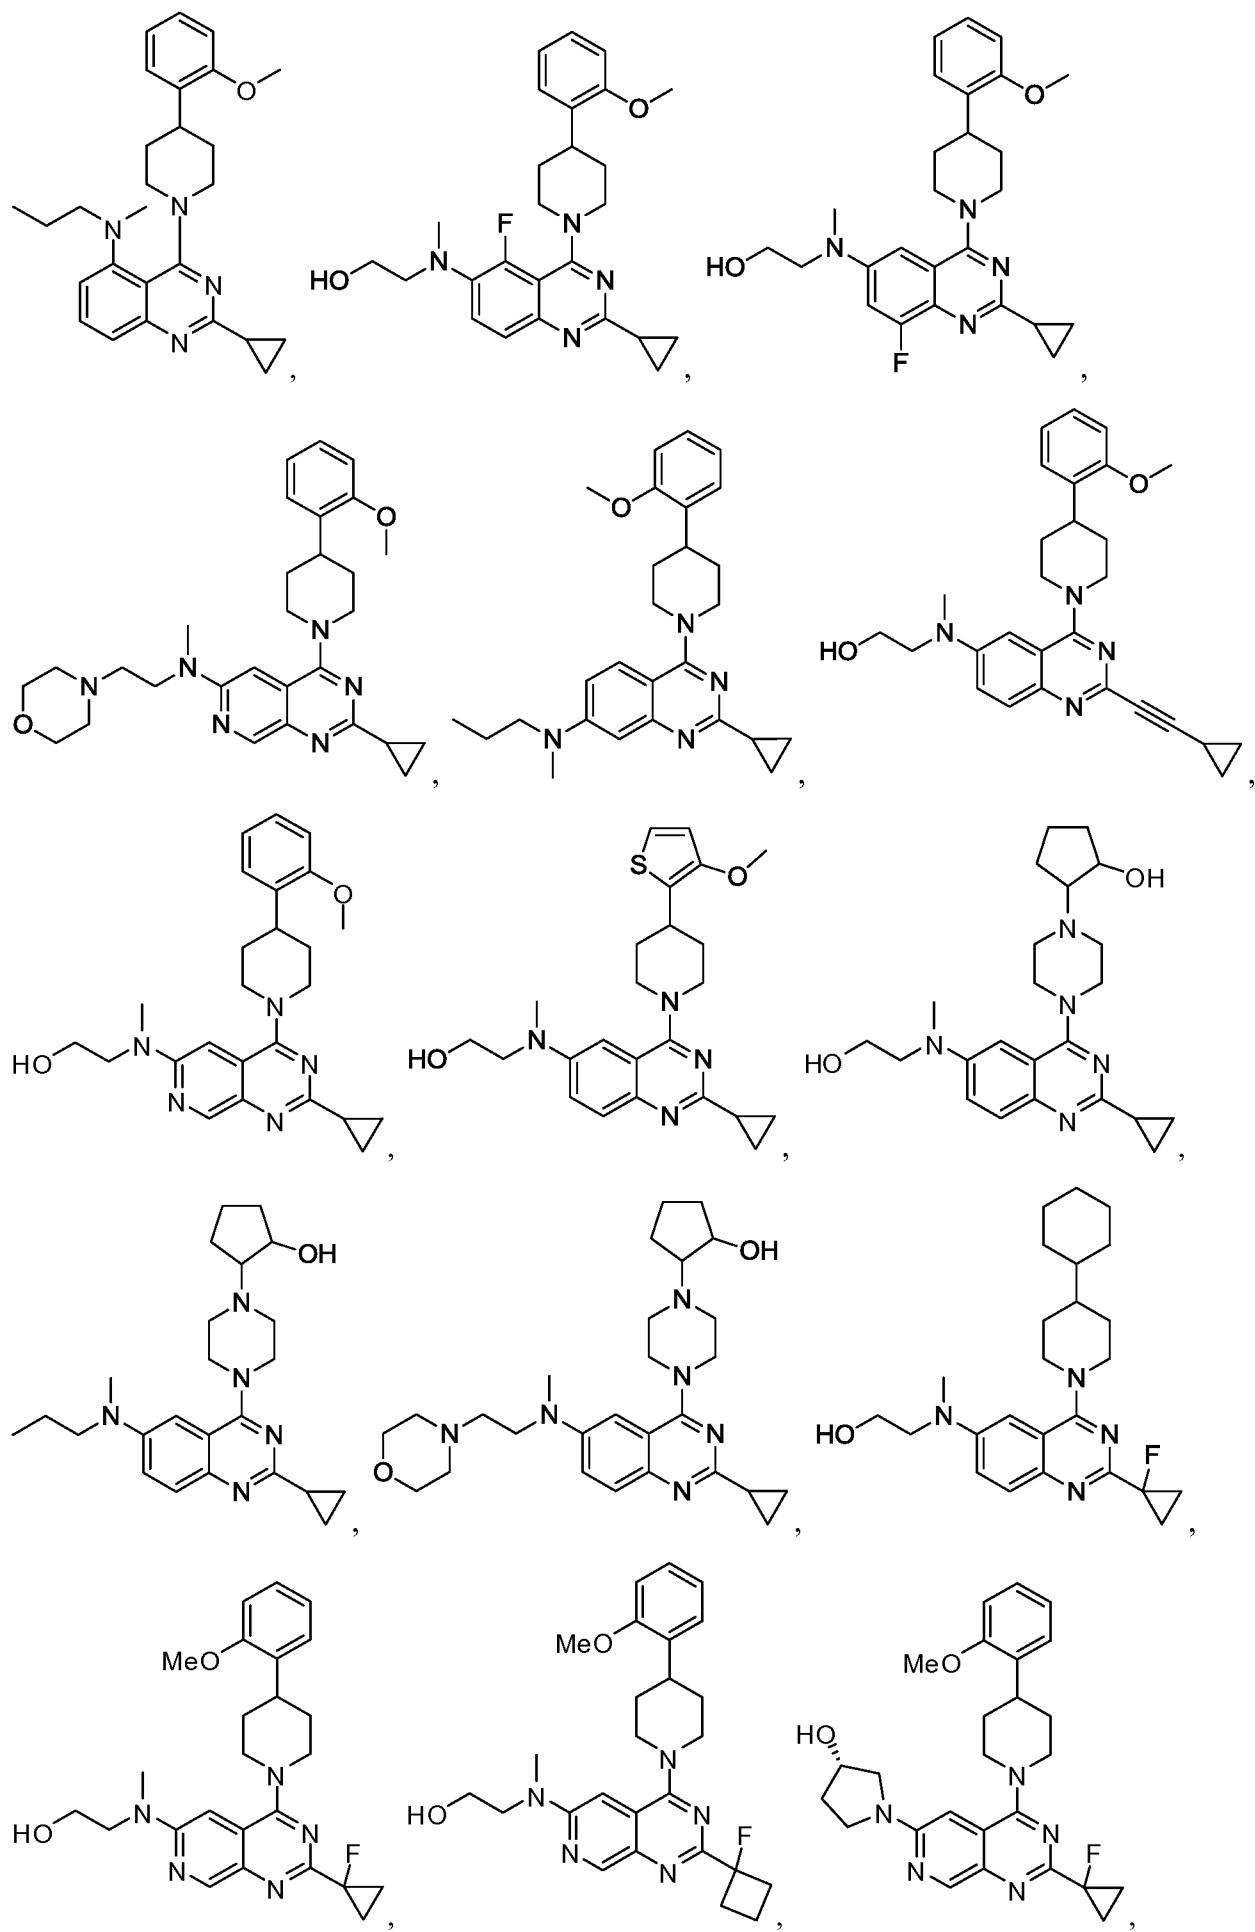

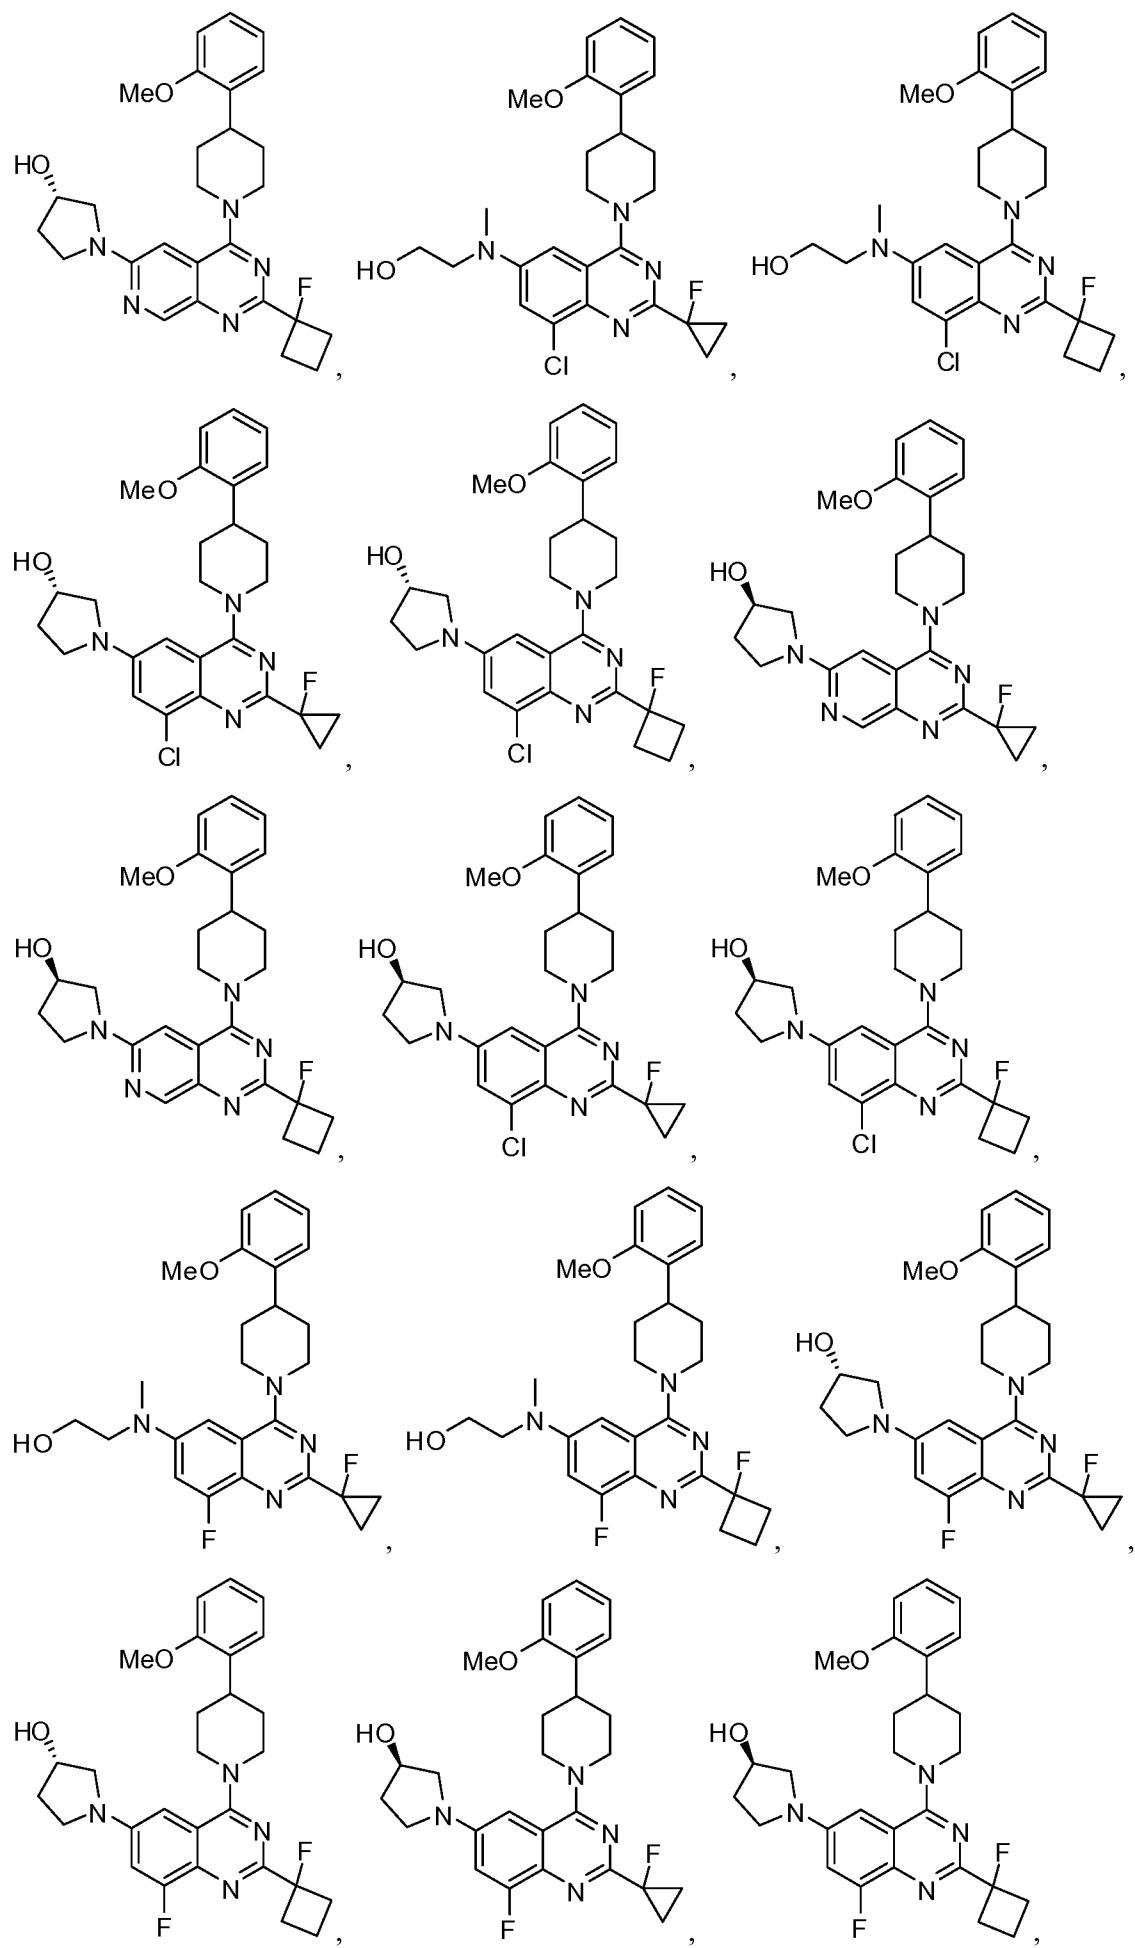

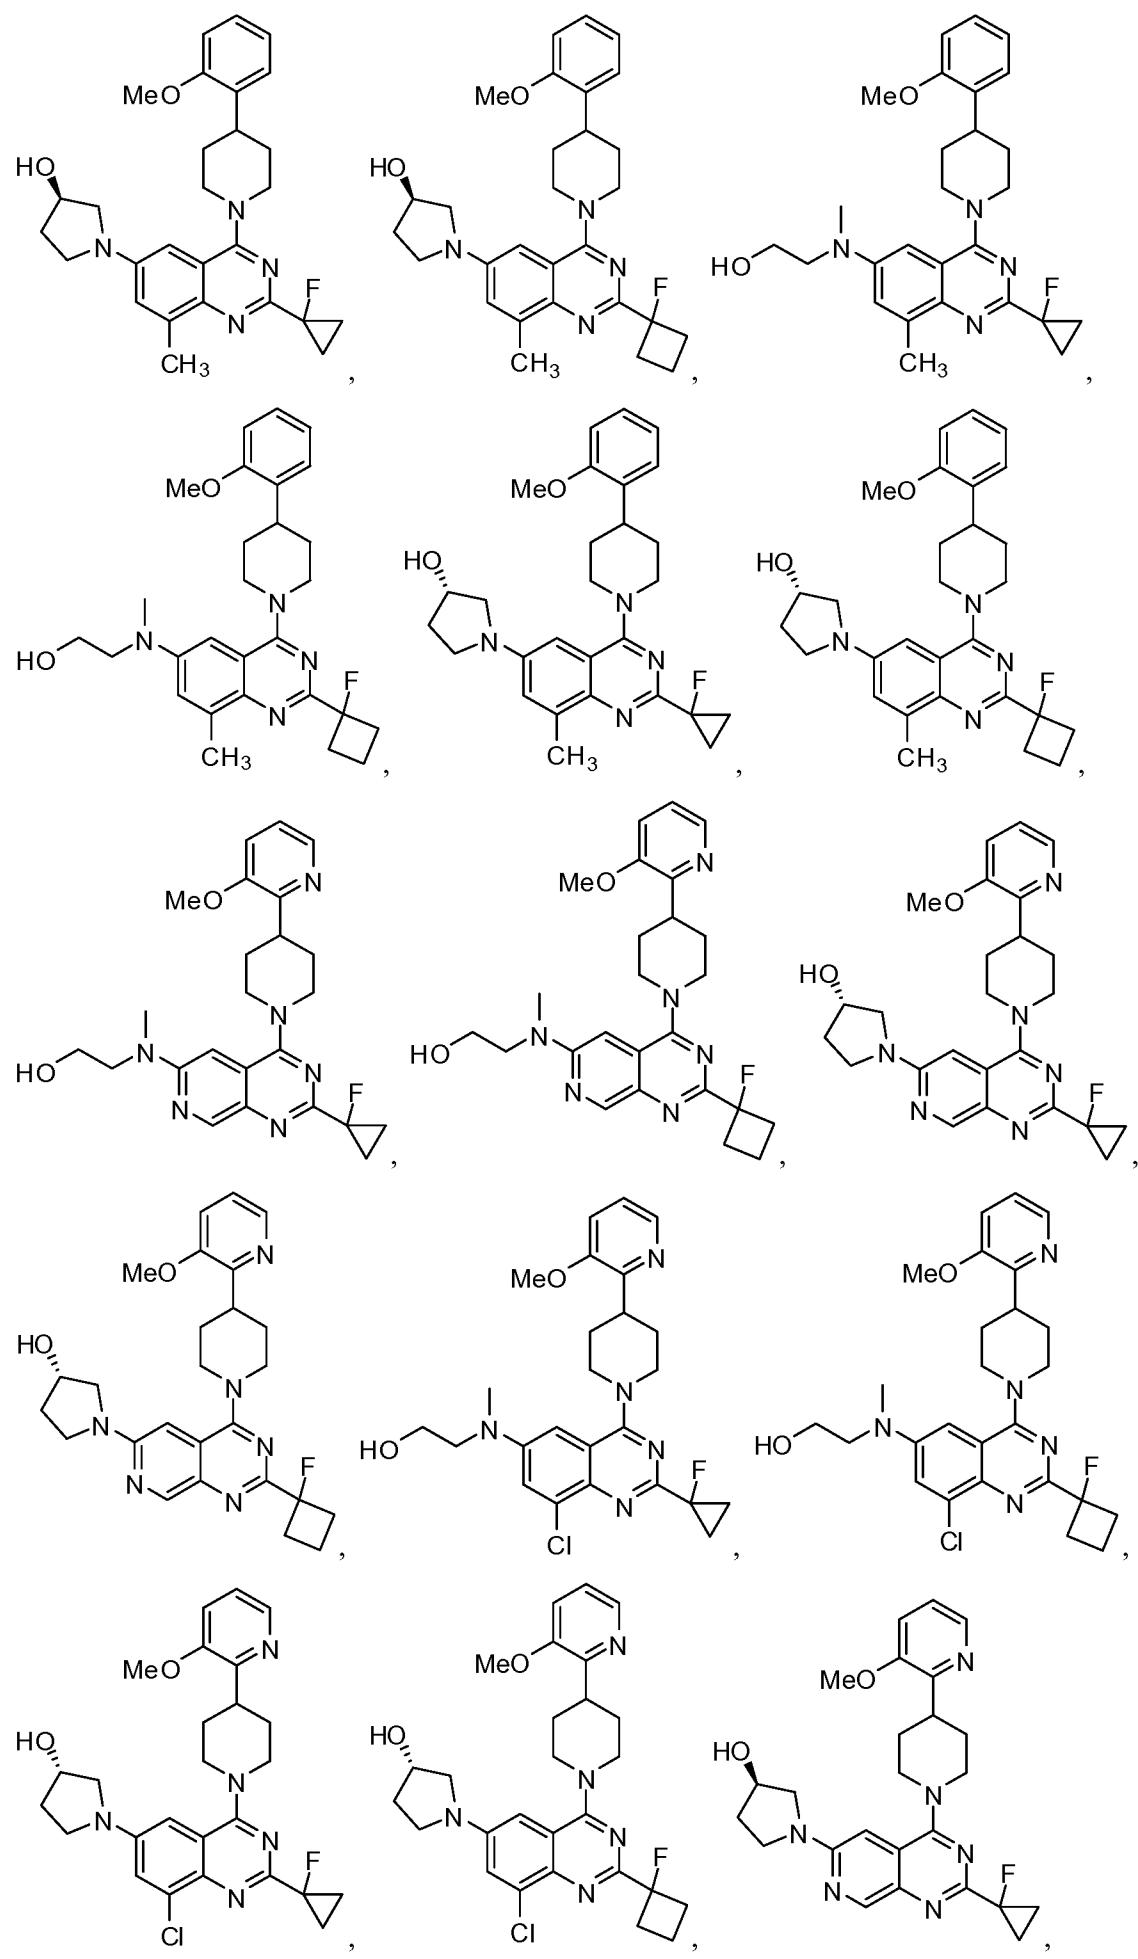

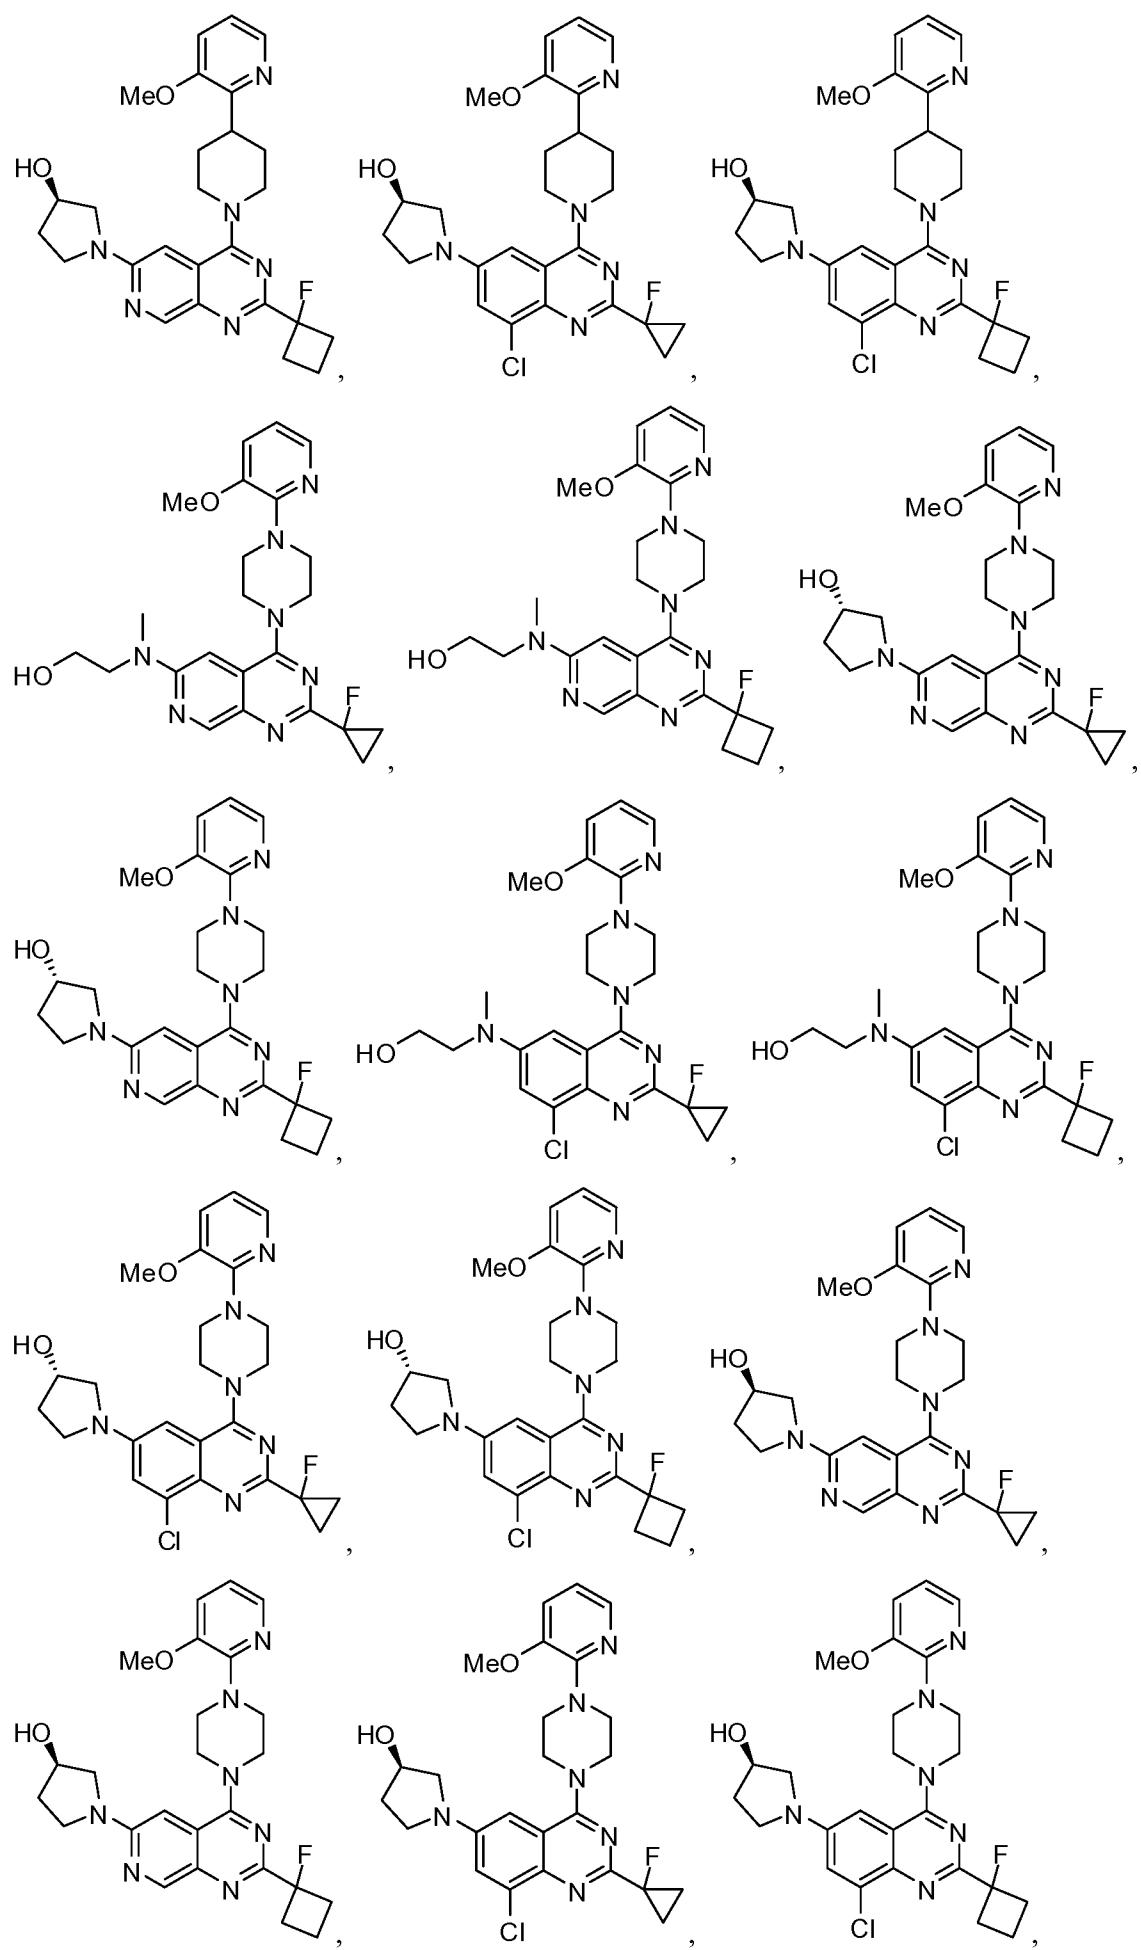

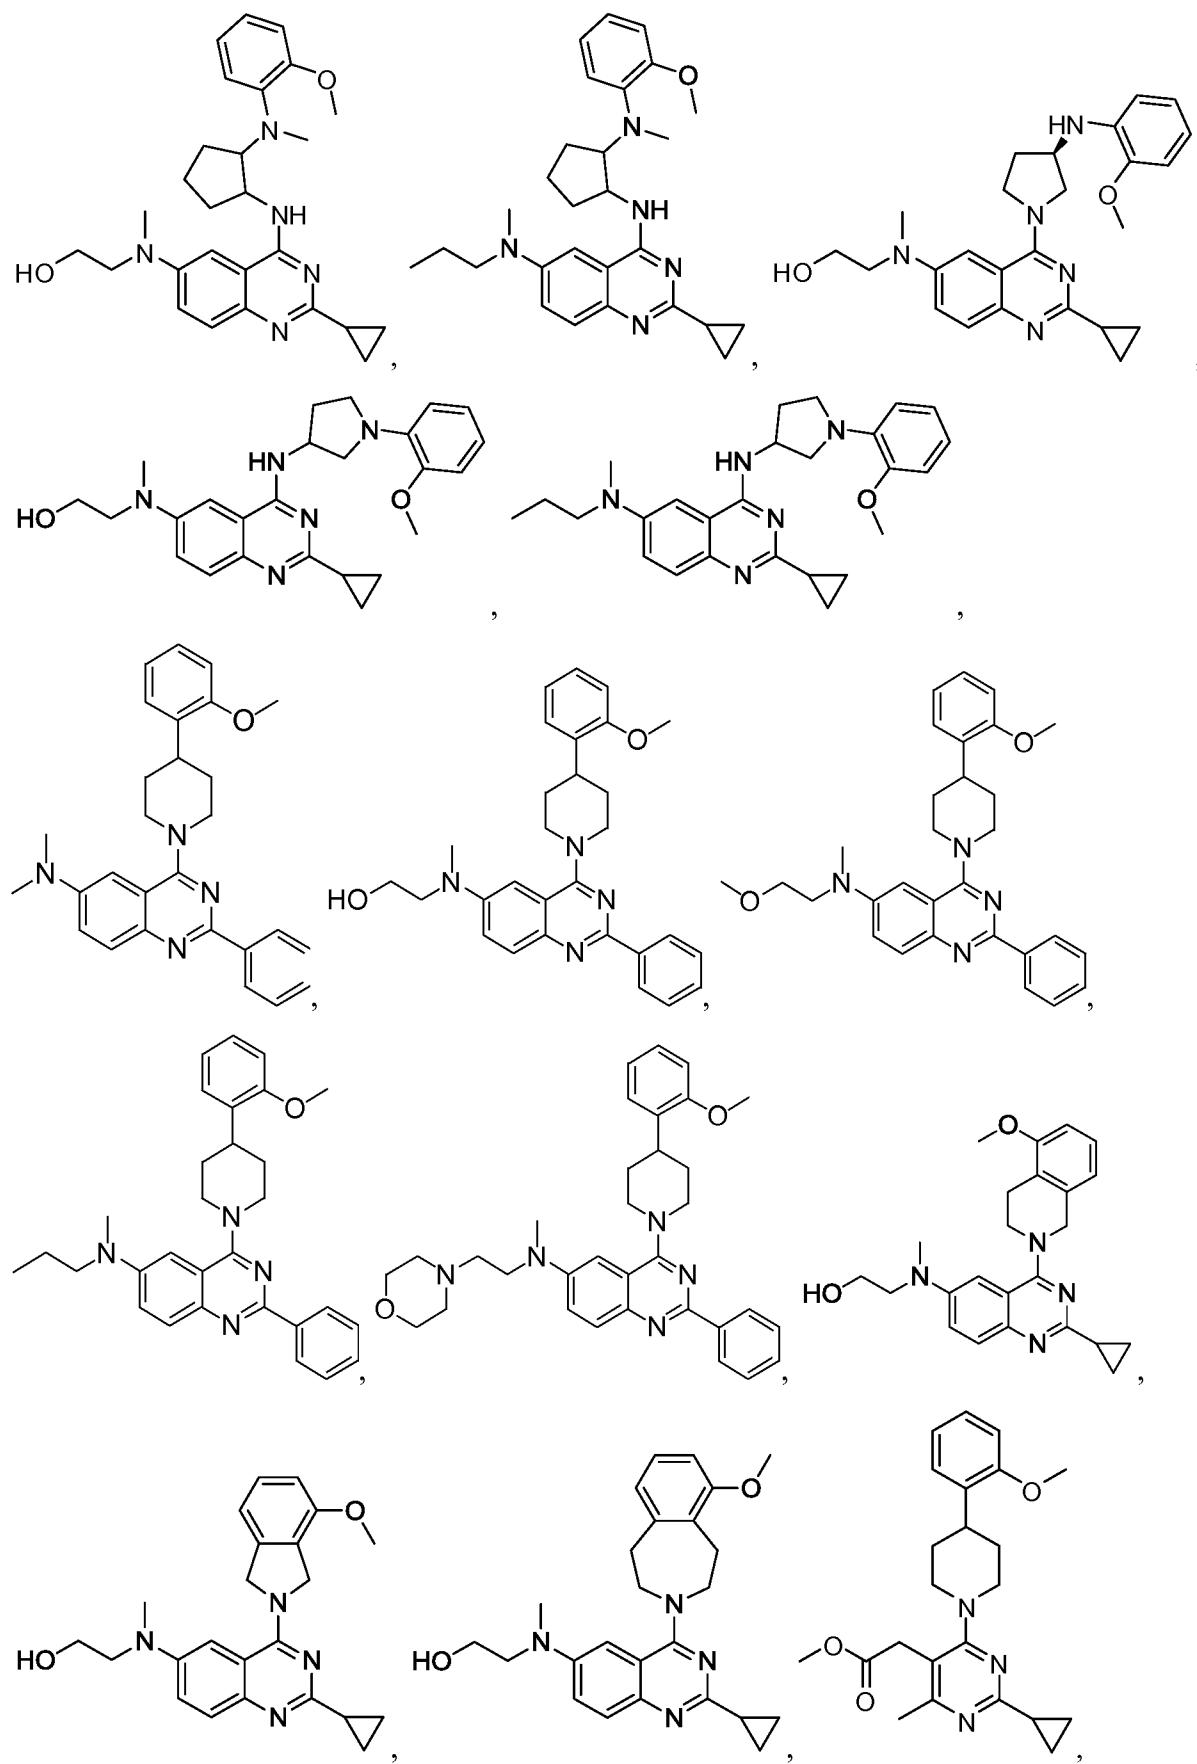

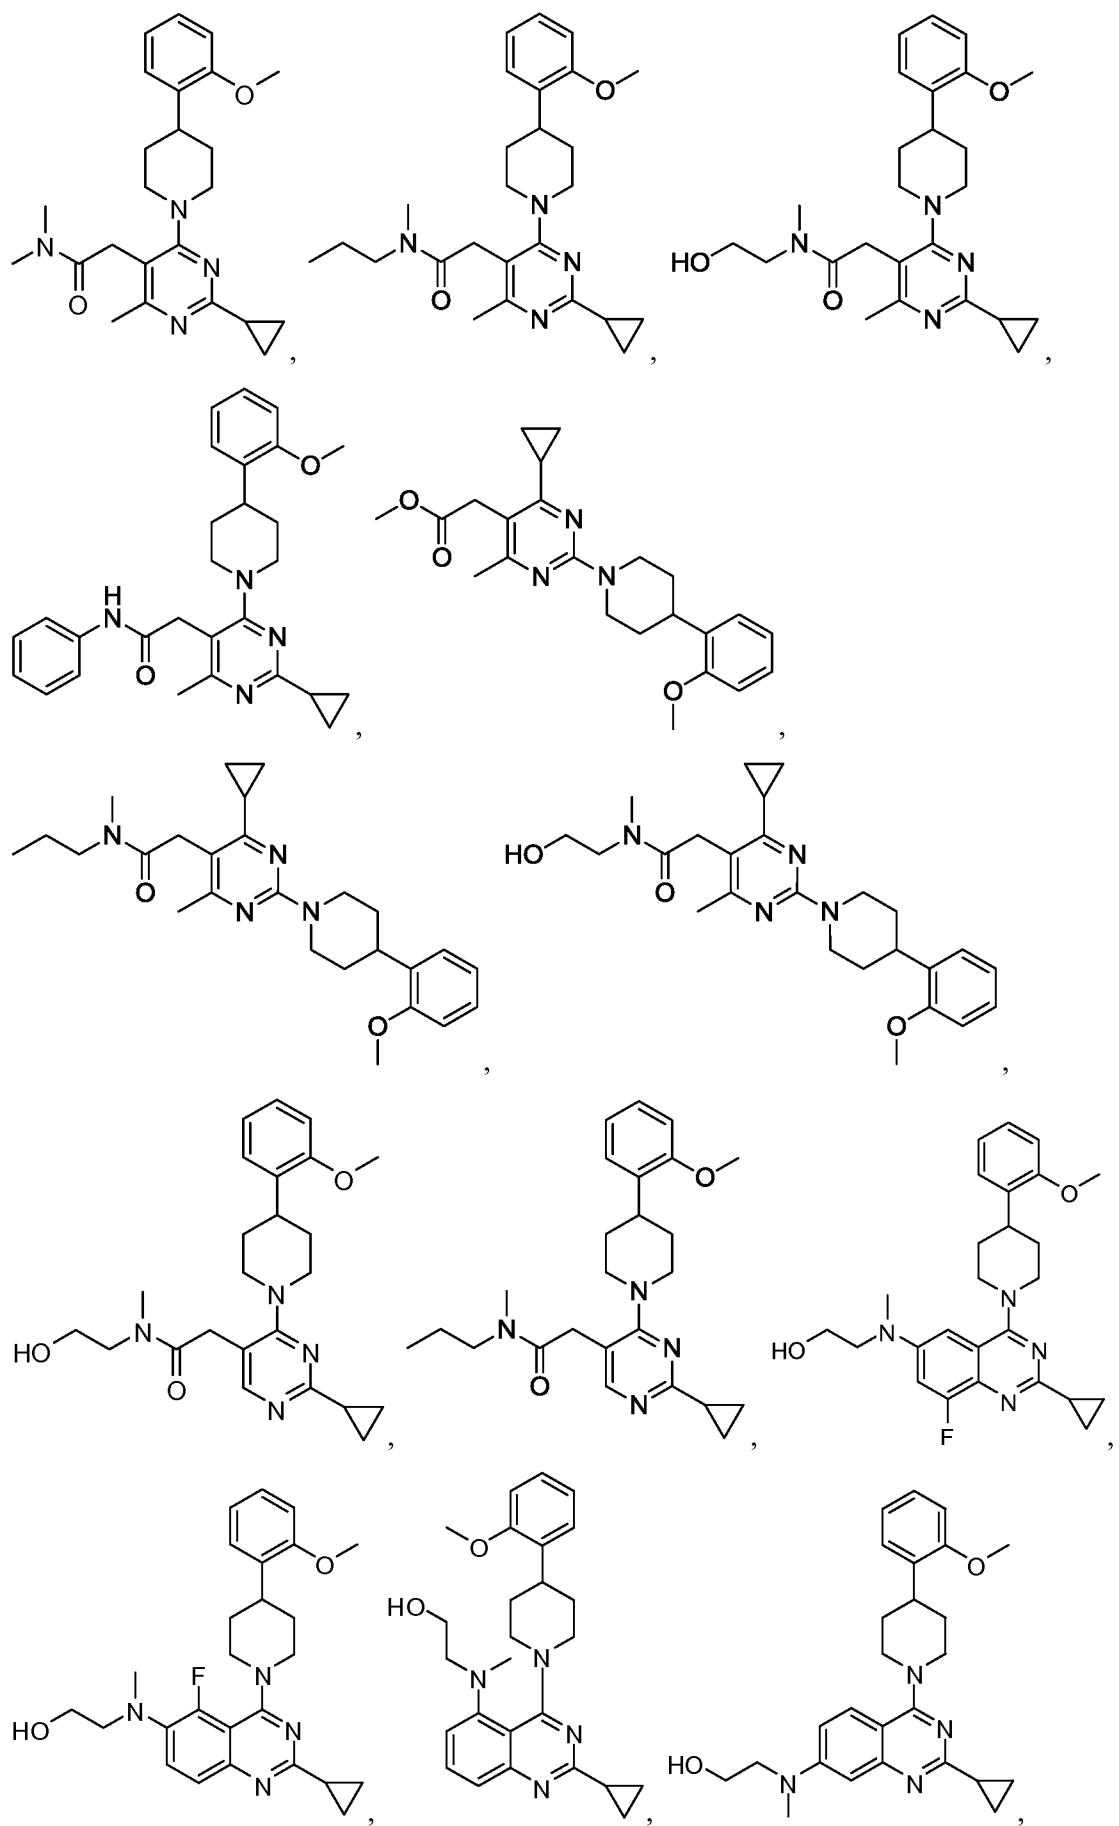

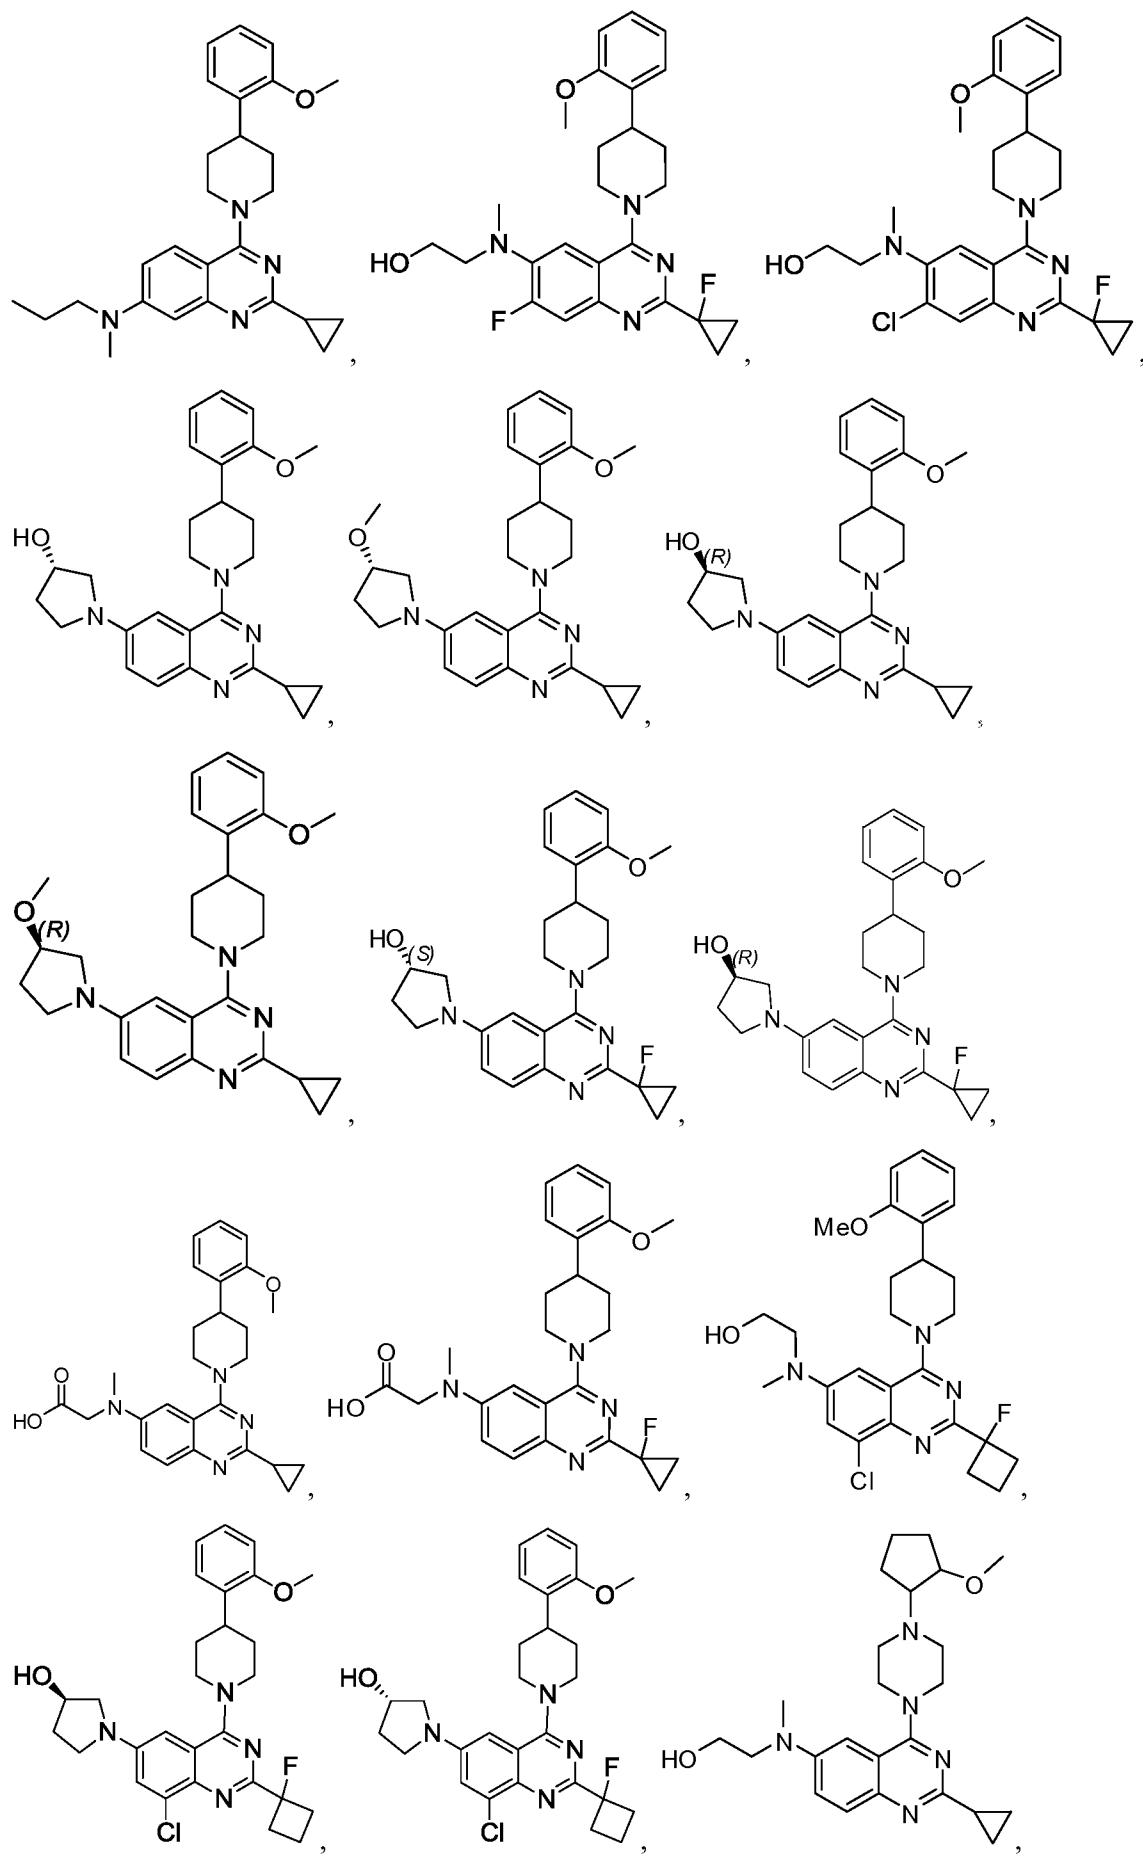

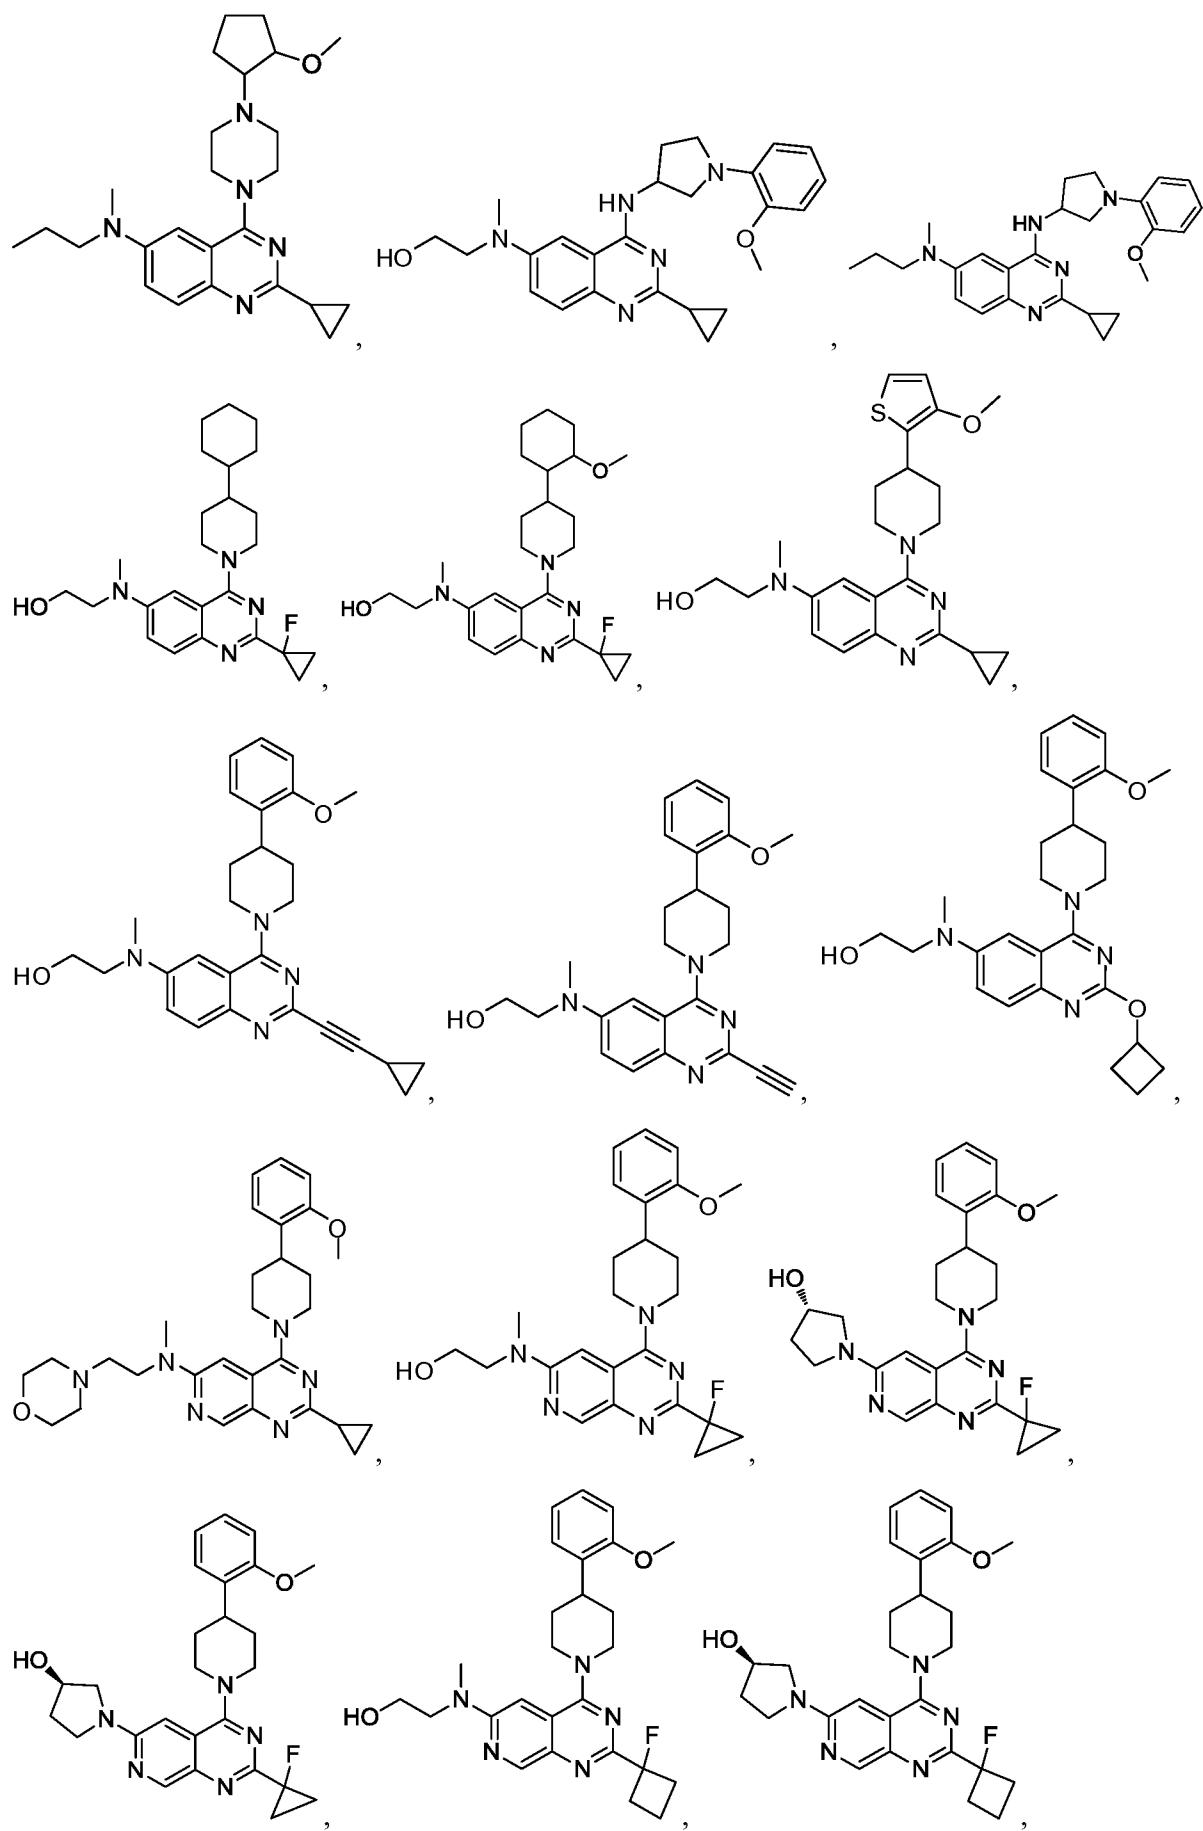

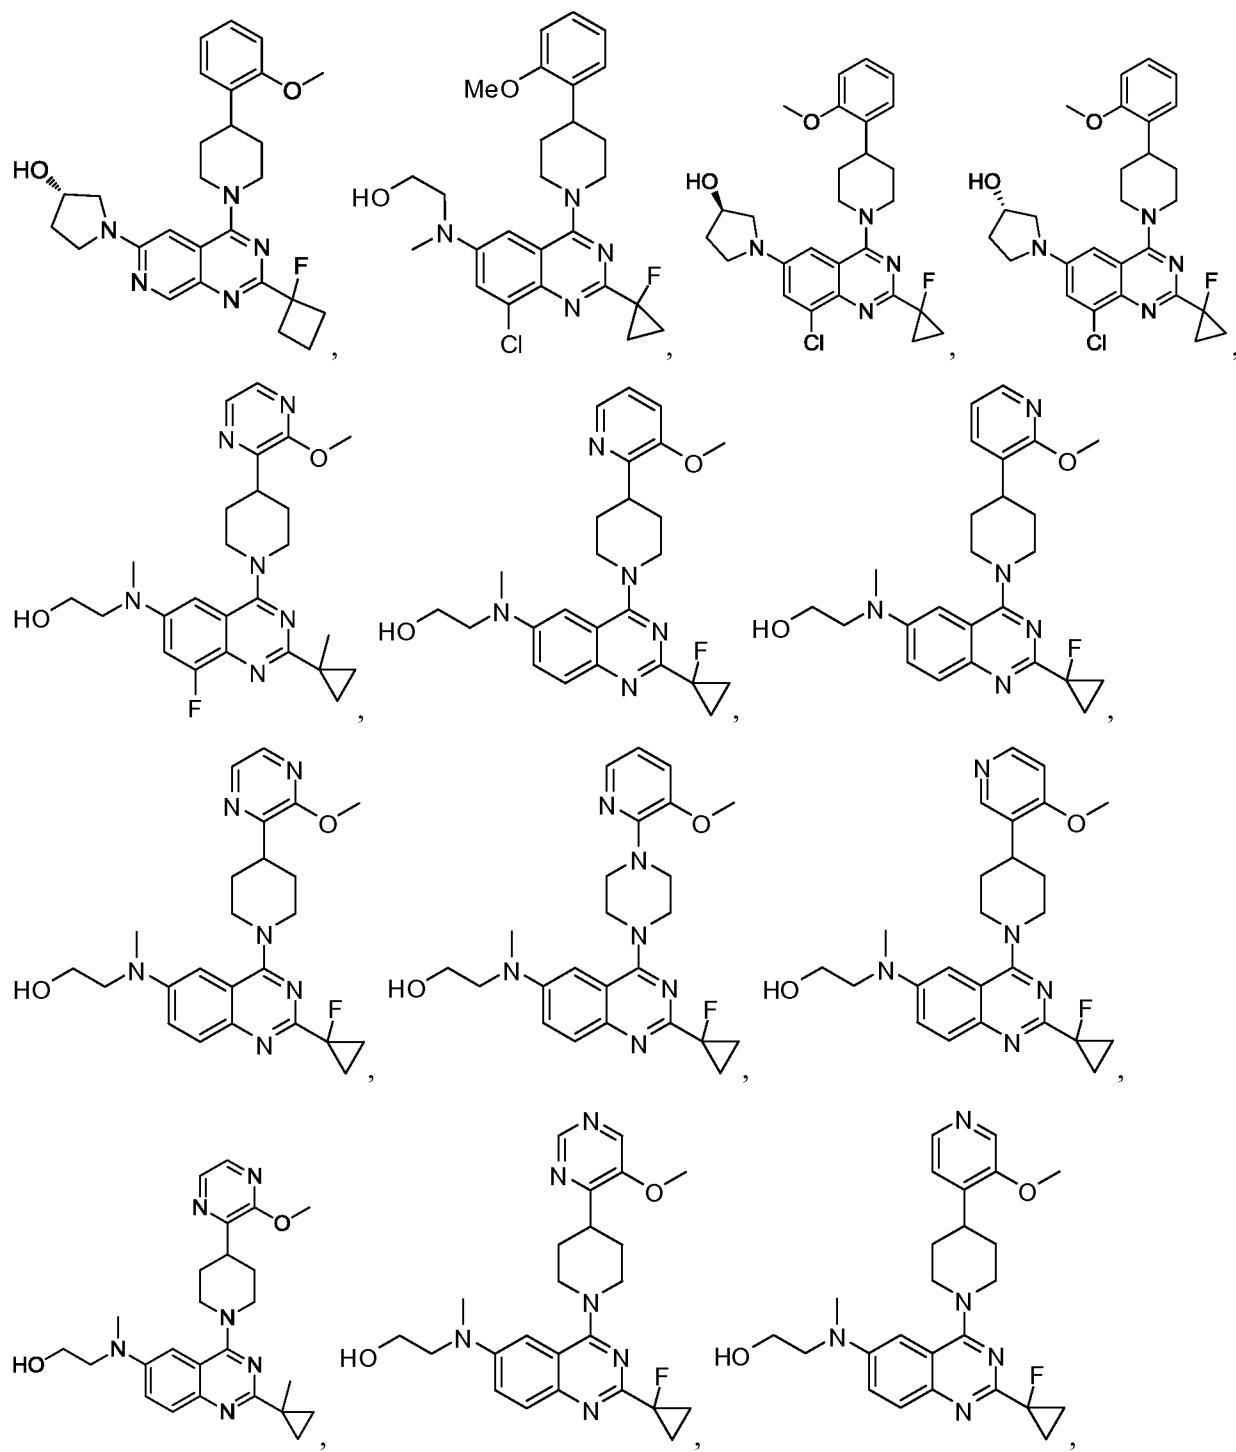

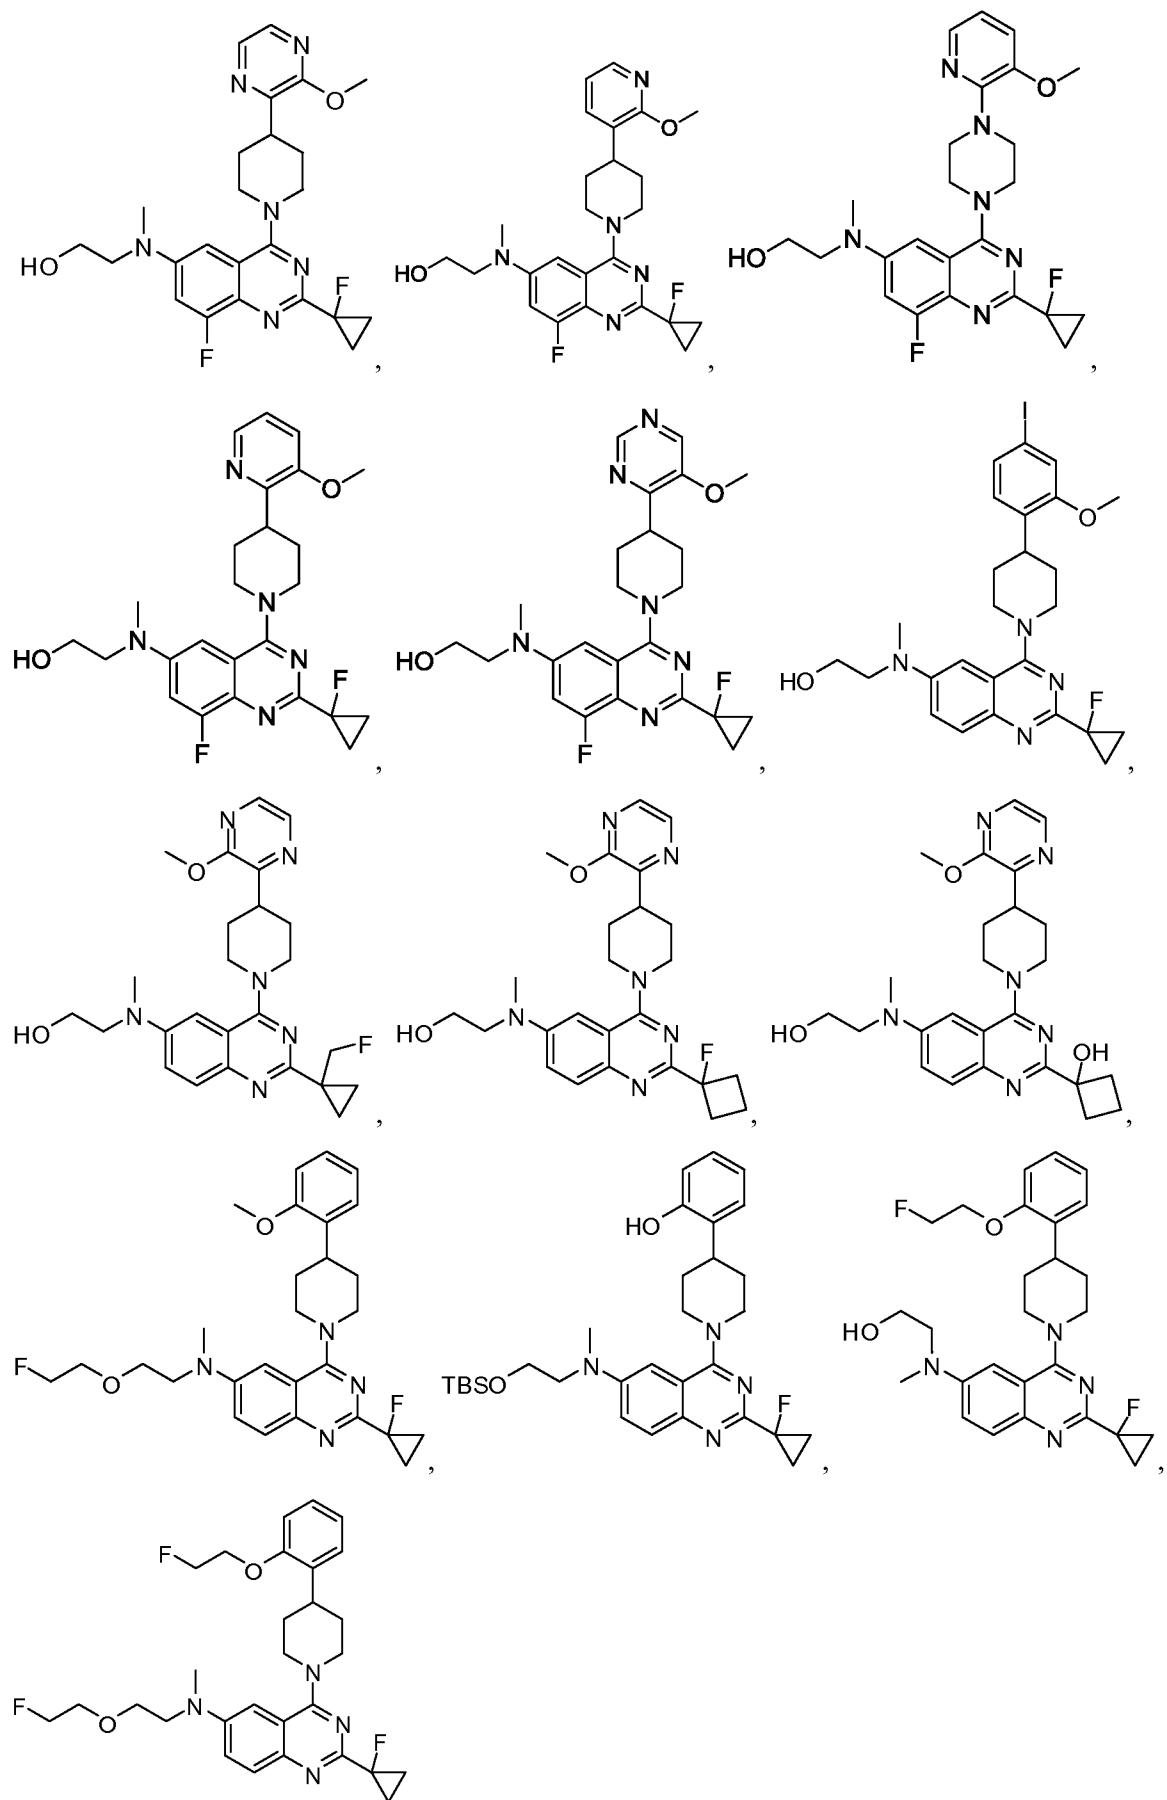

or pharmaceutically acceptable salt, solvate, prodrug, or N-oxide thereof of any one of the preceding compounds.

Further Forms of Compounds

[00197] In one aspect, the compound of Formula (I), (II), (III), (IV), (V), (VI), (VII) or (VIII), possesses one or more stereocenters and each stereocenter exists independently in either the R or S configuration. The compounds presented herein include all diastereomeric, enantiomeric, and epimeric forms as well as the appropriate mixtures thereof. The compounds and methods provided herein include all cis, trans, syn, anti, entgegen (E), and zusammen (Z) isomers as well as the appropriate mixtures thereof. In certain embodiments, compounds described herein are prepared as their individual stereoisomers by reacting a racemic mixture of the compound with an optically active resolving agent to form a pair of diastereoisomeric compounds/salts, separating the diastereomers and recovering the optically pure enantiomers. In some embodiments, resolution of enantiomers is carried out using covalent diastereomeric derivatives of the compounds described herein. In another embodiment, diastereomers are separated by separation/resolution techniques based upon differences in solubility. In other embodiments, separation of stereoisomers is performed by chromatography or by forming diastereomeric salts and separation by recrystallization, or chromatography, or any combination thereof. Jean Jacques, Andre Collet, Samuel H. Wilen, “Enantiomers, Racemates and Resolutions”, John Wiley And Sons, Inc., 1981. In one aspect, stereoisomers are obtained by stereoselective synthesis.

[00198] In some embodiments, compounds described herein are prepared as prodrugs. A “prodrug” refers to an agent that is converted into the parent drug *in vivo*. Prodrugs are often useful because, in some situations, they may be easier to administer than the parent drug. They may, for instance, be bioavailable by oral administration whereas the parent is not. The prodrug may also have improved solubility in pharmaceutical compositions over the parent drug. In some embodiments, the design of a prodrug increases the effective water solubility. An example, without limitation, of a prodrug is a compound described herein, which is administered as an ester (the “prodrug”) to facilitate transmittal across a cell membrane where water solubility is detrimental to mobility but which then is metabolically hydrolyzed to the carboxylic acid, the active entity, once inside the cell where water-solubility is beneficial. A further example of a prodrug might be a short peptide (polyaminoacid) bonded to an acid group where the peptide is metabolized to reveal the active moiety. In certain embodiments, upon *in vivo* administration, a prodrug is chemically converted to the biologically, pharmaceutically or therapeutically active form of the compound. In certain embodiments, a prodrug is enzymatically metabolized by one or more steps or processes to the biologically, pharmaceutically or therapeutically active form of the compound.

[00199] In one aspect, prodrugs are designed to alter the metabolic stability or the transport characteristics of a drug, to mask side effects or toxicity, to improve the flavor of a drug or to alter other characteristics or properties of a drug. By virtue of knowledge of pharmacokinetic, pharmacodynamic processes and drug metabolism *in vivo*, once a pharmaceutically active compound is known, the design prodrugs of the compound is possible. (see, for example, Nogradi (1985) *Medicinal Chemistry A Biochemical Approach*, Oxford University Press, New York, pages 388-392; Silverman (1992), *The Organic Chemistry of Drug Design and Drug Action*, Academic Press, Inc., San Diego, pages 352-401, Rooseboom *et al.*, *Pharmacological Reviews*, 56:53-102, 2004; Aesop Cho, “Recent Advances in Oral

Prodrug Discovery", *Annual Reports in Medicinal Chemistry*, Vol. 41, 395-407, 2006; T. Higuchi and V. Stella, *Pro-drugs as Novel Delivery Systems*, Vol. 14 of the A.C.S. Symposium Series).

[00200] In some cases, some of the herein-described compounds may be a prodrug for another derivative or active compound.

[00201] In some embodiments, sites on the aromatic ring portion of compounds described herein are susceptible to various metabolic reactions. Therefore incorporation of appropriate substituents on the aromatic ring structures will reduce, minimize or eliminate this metabolic pathway. In specific embodiments, the appropriate substituent to decrease or eliminate the susceptibility of the aromatic ring to metabolic reactions is, by way of example only, a halogen, or an alkyl group.

[00202] In another embodiment, the compounds described herein are labeled isotopically (e.g. with a radioisotope) or by another other means, including, but not limited to, the use of chromophores or fluorescent moieties, bioluminescent labels, or chemiluminescent labels.

[00203] Compounds described herein include isotopically-labeled compounds, which are identical to those recited in the various formulae and structures presented herein, but for the fact that one or more atoms are replaced by an atom having an atomic mass or mass number different from the atomic mass or mass number usually found in nature. Examples of isotopes that can be incorporated into the present compounds include isotopes of hydrogen, carbon, nitrogen, oxygen, sulfur, fluorine and chlorine, such as, for example, ²H, ³H, ¹³C, ¹⁴C, ¹⁵N, ¹⁸O, ¹⁷O, ³⁵S, ¹⁸F, ³⁶Cl. In one aspect, isotopically-labeled compounds described herein, for example those into which radioactive isotopes such as ³H and ¹⁴C are incorporated, are useful in drug and/or substrate tissue distribution assays. In one aspect, substitution with isotopes such as deuterium affords certain therapeutic advantages resulting from greater metabolic stability, such as, for example, increased *in vivo* half-life or reduced dosage requirements.

[00204] In additional or further embodiments, the compounds described herein are metabolized upon administration to an organism in need to produce a metabolite that is then used to produce a desired effect, including a desired therapeutic effect.

[00205] "Pharmaceutically acceptable" as used herein, refers a material, such as a carrier or diluent, which does not abrogate the biological activity or properties of the compound, and is relatively nontoxic, i.e., the material may be administered to an individual without causing undesirable biological effects or interacting in a deleterious manner with any of the components of the composition in which it is contained.

[00206] The term "pharmaceutically acceptable salt" refers to a formulation of a compound that does not cause significant irritation to an organism to which it is administered and does not abrogate the biological activity and properties of the compound. In some embodiments, pharmaceutically acceptable salts are obtained by reacting a compound of Formula (I), (II), (III), (IV), (V), (VI), (VII) or (VIII) with acids. Pharmaceutically acceptable salts are also obtained by reacting a compound of Formula (I), (II), (III), (IV), (V), (VI), (VII) or (VIII) with a base to form a salt.

[00207] Compounds described herein may be formed as, and/or used as, pharmaceutically acceptable salts. The type of pharmaceutical acceptable salts, include, but are not limited to: (1) acid addition salts,

formed by reacting the free base form of the compound with a pharmaceutically acceptable: inorganic acid, such as, for example, hydrochloric acid, hydrobromic acid, sulfuric acid, phosphoric acid, metaphosphoric acid, and the like; or with an organic acid, such as, for example, acetic acid, propionic acid, hexanoic acid, cyclopentanepropionic acid, glycolic acid, pyruvic acid, lactic acid, malonic acid, succinic acid, malic acid, maleic acid, fumaric acid, trifluoroacetic acid, tartaric acid, citric acid, benzoic acid, 3-(4-hydroxybenzoyl)benzoic acid, cinnamic acid, mandelic acid, methanesulfonic acid, ethanesulfonic acid, 1,2-ethanedisulfonic acid, 2-hydroxyethanesulfonic acid, benzenesulfonic acid, toluenesulfonic acid, 2-naphthalenesulfonic acid, 4-methylbicyclo-[2.2.2]oct-2-ene-1-carboxylic acid, glucoheptonic acid, 4,4'-methylenebis-(3-hydroxy-2-ene-1-carboxylic acid), 3-phenylpropionic acid, trimethylacetic acid, tertiary butylacetic acid, lauryl sulfuric acid, gluconic acid, glutamic acid, hydroxynaphthoic acid, salicylic acid, stearic acid, muconic acid, butyric acid, phenylacetic acid, phenylbutyric acid, valproic acid, and the like; (2) salts formed when an acidic proton present in the parent compound is replaced by a metal ion, e.g., an alkali metal ion (e.g. lithium, sodium, potassium), an alkaline earth ion (e.g. magnesium, or calcium), or an aluminum ion. In some cases, compounds described herein may coordinate with an organic base, such as, but not limited to, ethanolamine, diethanolamine, triethanolamine, tromethamine, N-methylglucamine, dicyclohexylamine, tris(hydroxymethyl)methylamine. In other cases, compounds described herein may form salts with amino acids such as, but not limited to, arginine, lysine, and the like. Acceptable inorganic bases used to form salts with compounds that include an acidic proton, include, but are not limited to, aluminum hydroxide, calcium hydroxide, potassium hydroxide, sodium carbonate, sodium hydroxide, and the like.

[00208] It should be understood that a reference to a pharmaceutically acceptable salt includes the solvent addition forms, particularly solvates. Solvates contain either stoichiometric or non-stoichiometric amounts of a solvent, and may be formed during the process of crystallization with pharmaceutically acceptable solvents such as water, ethanol, and the like. Hydrates are formed when the solvent is water, or alcoholates are formed when the solvent is alcohol. Solvates of compounds described herein can be conveniently prepared or formed during the processes described herein. In addition, the compounds provided herein can exist in unsolvated as well as solvated forms. In general, the solvated forms are considered equivalent to the unsolvated forms for the purposes of the compounds and methods provided herein.

Synthesis of Compounds

[00209] In some embodiments, the synthesis of compounds described herein are accomplished using means described in the chemical literature, using the methods described herein, or by a combination thereof. In addition, solvents, temperatures and other reaction conditions presented herein may vary.

[00210] In other embodiments, the starting materials and reagents used for the synthesis of the compounds described herein are synthesized or are obtained from commercial sources, such as, but not limited to, Sigma-Aldrich, FisherScientific (Fisher Chemicals), and AcrosOrganics.

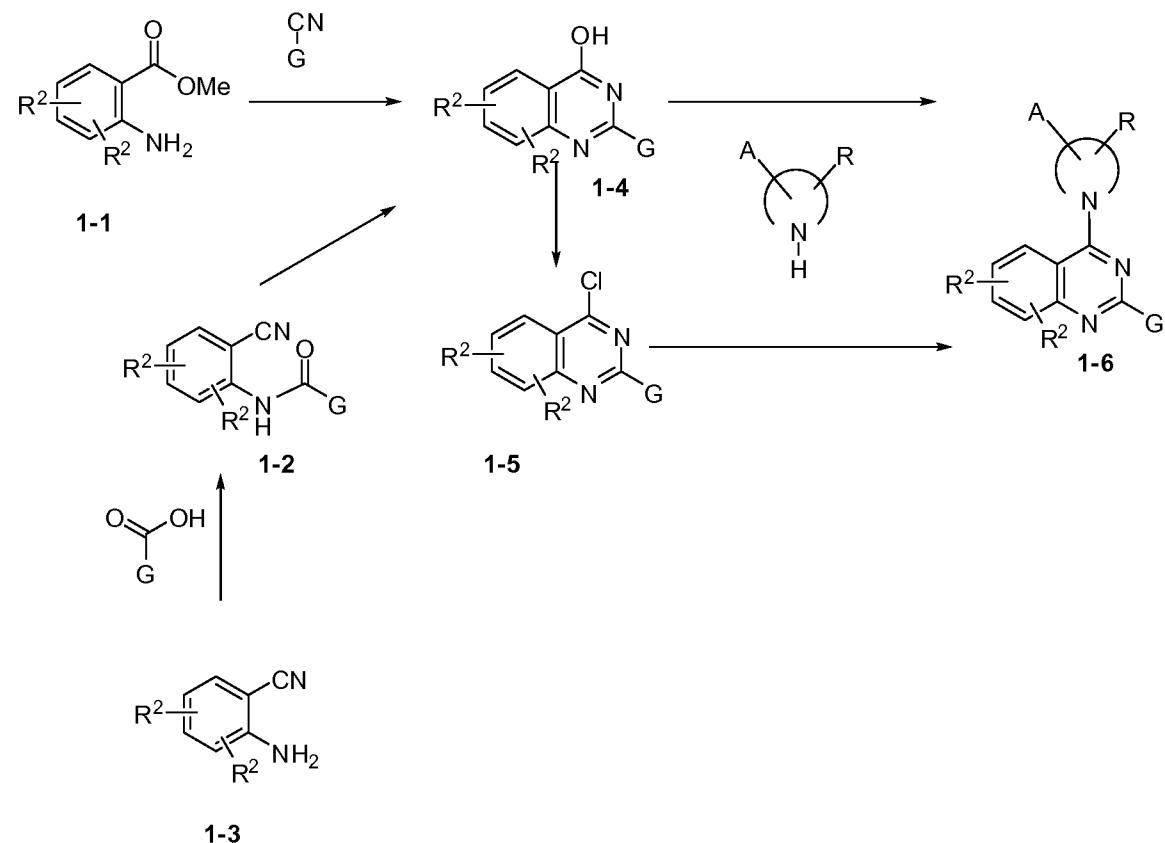

[00211] In further embodiments, the compounds described herein, and other related compounds having different substituents are synthesized using techniques and materials described herein as well as those that

General methods for the preparation of compounds as disclosed herein may be derived from reactions and the reactions may be modified by the use of appropriate reagents and conditions, for the introduction of the various moieties found in the formulae as provided herein. As a guide the following synthetic methods may be utilized.

[00212] In the reactions described, it may be necessary to protect reactive functional groups, for example hydroxy, amino, imino, thio or carboxy groups, where these are desired in the final product, in order to avoid their unwanted participation in reactions. A detailed description of techniques applicable to the creation of protecting groups and their removal are described in Greene and Wuts, Protective Groups in Organic Synthesis, 3rd Ed., John Wiley & Sons, New York, NY, 1999, and Kocienski, Protective Groups, Thieme Verlag, New York, NY, 1994, which are incorporated herein by reference for such disclosure).

[00213] In some embodiments, compounds described herein are prepared as shown in Scheme A.

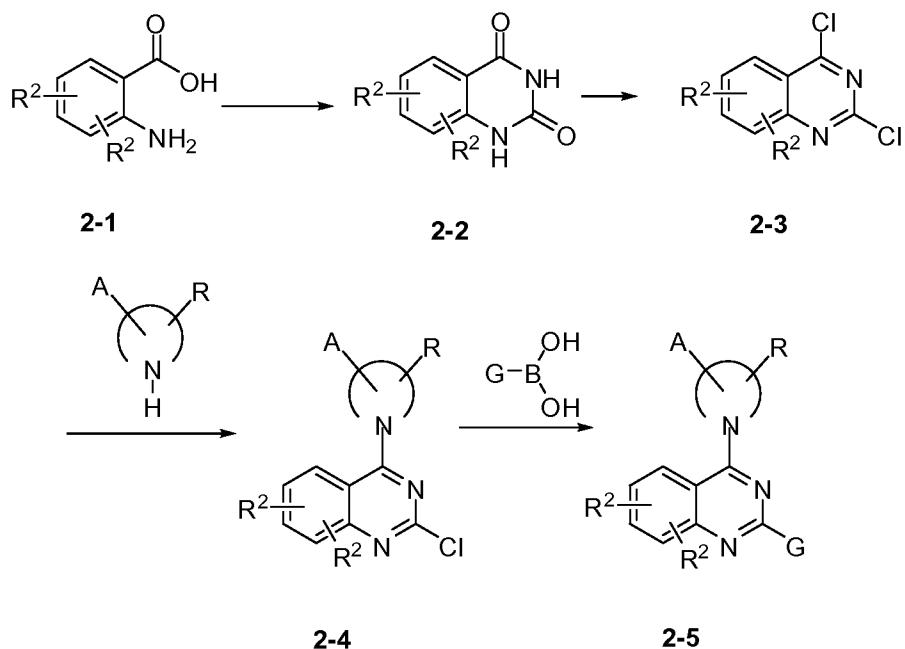

Scheme A

[00214] In some embodiments, the synthesis of quinazoline-derived compounds **1-6** described herein is accomplished starting from suitably substituted methyl anthranilates **1-1** as shown in Scheme A. Acid catalyzed (i.e. HCl) condensation of substituted methyl anthranilates (**1-1**) with substituted carbonitrile affords 4-hydroxyquinazoline intermediates (**1-4**). Chlorination (i.e. POCl₃) of the 4-hydroxyquinazoline intermediates followed by amination of the resulting 4-chloroquinazoline intermediates (**1-5**) with various substituted aryl piperidines, piperazines or pyrrolidines affords quinazoline analogs **1-6**. In some embodiments, the 4-hydroxyquinazoline intermediates (**1-4**) are directly reacted with various substituted aryl piperidines, piperazines or pyrrolidines using a coupling reagent (i.e. BOP) and a base (i.e. DBU) to afford quinazoline analogs **1-6**. In some embodiments, the synthesis of the 4-hydroxyquinazoline intermediates (**1-4**) is accomplished in two steps by 1) amide condensation of a substituted anthranilonitrile (**1-3**) and a substituted carboxylic acid using an amide coupling reagent (i.e HATU) to afford N-(2-cyanophenyl)amide derivatives **1-2** and 2) cyclization under basic (i.e. NaOH) and oxidative (i.e. H₂O₂) conditions to afford 4-hydroxyquinazoline intermediates (**1-4**).

[00215] In some embodiments, compounds described herein are prepared as shown in Scheme B.

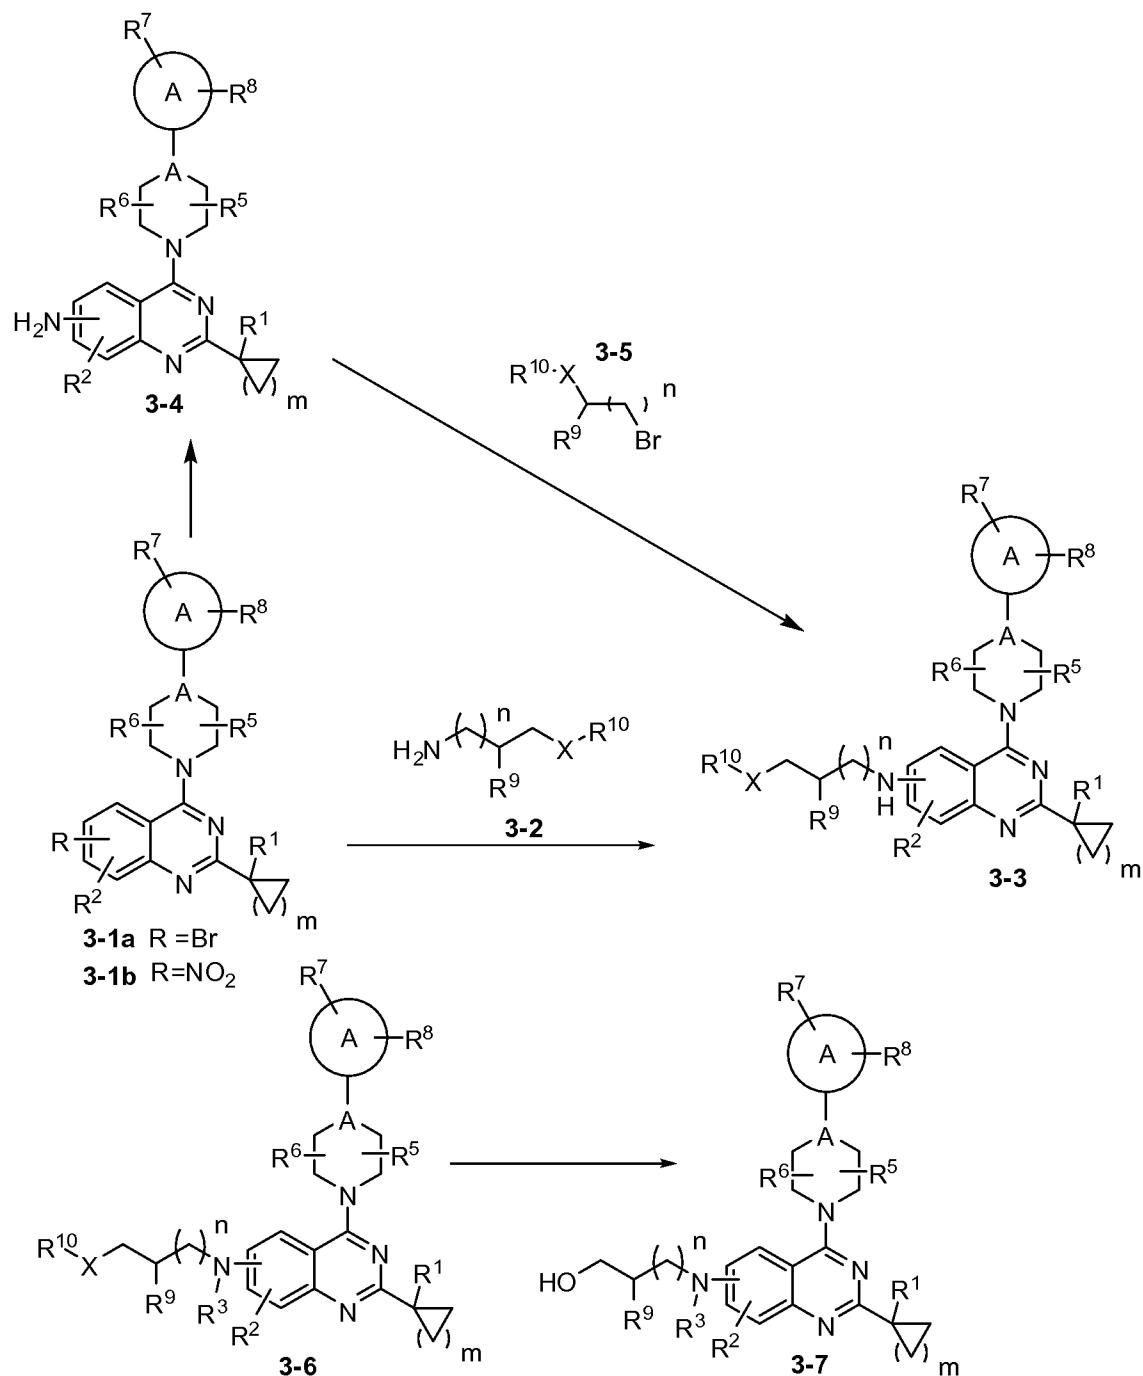

Scheme B:

[00216] In some embodiments, suitably substituted anthranilic acids **2-1** are used to prepare quinazoline compounds **2-5** as shown in Scheme B. In some embodiments, cyclization of anthranilic acid **2-1** with a cyanate salt (i.e. KO CN) affords quinazoline-(1H,3H)-dione compound **2-2**. In some embodiments, quinazoline-(1H,3H)-dione compound **2-2** is chlorinated to yield 2,4-dichloroquinazoline compound **2-3**. In some embodiments, the chlorinating agent is POCl₃. In some embodiments, dichloroquinazoline compound **2-3** are selectively aminated at the 4-position using an optionally substituted aryl piperidine, aryl piperazines or aryl pyrrolidines to yield compounds of structure **2-4**. Tautomers are compounds that are interconvertible by migration of a hydrogen atom, accompanied by a switch of a single bond and adjacent double bond. In bonding arrangements where tautomerization is possible, a chemical equilibrium of the tautomers will exist. All tautomeric forms of the compounds disclosed herein are contemplated. The exact ratio of the tautomers depends on several factors, including temperature, solvent, and pH. Some examples of tautomeric interconversions include:

EXAMPLES

[00289] The following examples are intended to illustrate but not limit the disclosed embodiments. All reactions involving air and moisture-sensitive reagents and solvents were performed under a nitrogen atmosphere using standard chemical techniques. Anhydrous solvents were purchased and freshly used from Sigma-Aldrich or EMD Biosciences. All organic reagents were used as purchased. Analytical thin-layer chromatography was performed on Partisil K6F silica gel 60 Å, 250 µm. Microwave-assisted reactions were performed using a CEM Discover system. ^1H and ^{13}C chemical shifts are reported in δ values in ppm in the corresponding solvent. All solvents used for chromatography on the synthetic materials were Fisher Scientific HPLC grade, and the water was Millipore Milli-Q PP filtered. LCMS analysis of synthetic materials was completed on a Waters Autopurification system, which consists of a 2767 sample manager, a 2545 binary gradient module, a system fluidics organizer, a 2489 UV/vis detector, and a 3100 mass detector, all controlled with MassLynx software. A Sunfire Analytical C18 5 µm column (4.6 × 50 mm) and stepwise gradient {10% [(MeCN + 0.1% TFA) in (water + 0.1% TFA)] to 98% [(MeCN + 0.1% TFA) in (water + 0.1% TFA)] for 9 min.} was used for analytical LCMS of final compounds. The final compounds were purified by silica gel flash chromatography with ethyl acetate/hexanes as the eluant. All NMR spectra for the synthetic materials were recorded on a Bruker Avance II 400 or DRX-500 MHz instrument. The MestReNova 7 program was used to process and interpret NMR spectra. High Resolution Mass Spectrometry (HRMS) spectra were carried out on an Agilent 6224A Accurate-Mass Time-of-Flight (TOF) LC/MS system with electron spray ionization (ESI).

[00479] To a stirred solution of (6-chloro-pyridin-3-yl)-carbamic acid tert-butyl ester (5.6 g, 24.6 mmol) in THF (100 mL) was added n-BuLi (29 mL, 74.0 mmol) dropwise at -78 °C. The mixture was stirred at this temperature for 1 hours. Then the vessel was charged with carbon dioxide to a pressure of 0.7 Mbar and stirred at - 40 °C for 10 min. After warmed to room temperature, the mixture was poured into the ice water and the pH value was adjusted to pH = 3. The aqueous phase was extracted with EA (100 mL x2). The combined organic layers were washed with brine (30 mL x2), dried over anhydrous Na₂SO₄ and

The reaction was cooled to room temperature and was concentrated *in vacuum*. The residue was diluted with water. The aqueous mixture was neutralized with sat. NaHCO₃ to pH = 8 and extracted with EA (100 mL x2). The combined organic layers were washed with brine (50 mL), dried over anhydrous Na₂SO₄ and filtered. The filtrate was evaporated *in vacuum* to residue, which was purified by silica gel chromatography (from PE to PE/EA = 2/1) to give (1.1 g, two steps of yield: 24%) of 5-amino-2-chloro-isonicotinic acid methyl ester as yellow solid.

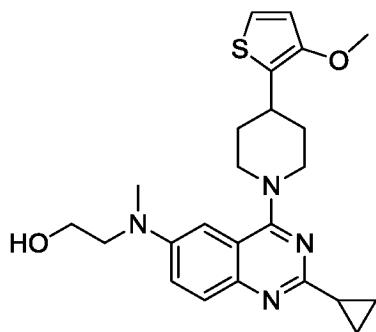

[00481] To a stirred solution of (5-amino-2-chloro-isonicotinic acid methyl ester (1.3 g, 7 mmol) in DCM (30 mL) was added Et₃N (1.4 g, 14 mmol) and cyclopropanecarbonyl chloride (1.1 g, 10.5 mmol) at 0 °C. The mixture was stirred at room temperature overnight. The mixture was evaporated *in vacuum*. The residue (180 mg, yield: 51 %) was washed with methanol and used directly in next step without further purification.

[00484] To a stirred solution of 6-chloro-2-cyclopropyl-4-[4-(2-methoxy-phenyl)-piperidin-1-yl]-pyrido-[3,4-d]pyrimidine (60 mg, 0.15 mmol) in NMP (1 mL) was added DIEA (40 mg, 0.3 mmol) and 4-(2-methoxy-phenyl)-piperidine (68 mg, 0.9 mmol). [00500] To a solution of 2-[(2-methoxy-phenyl)-methyl-amino]-cyclopentanol (2.2 g, 9.95 mmol) in DCM was added methanesulfonyl chloride (1.24 g, 11 mmol) and the mixture was stirred at r.t. for 1 hour. The reaction was quenched with water (100 mL) and the mixture was extracted with EA (100 mL). The extracts were dried over Na_2SO_4 . The organic layer was concentrated in vacuum and the crude for the next step without further purification.

[00501] The crude product was dissolved in DMF (40 mL) and then NaN_3 (715 mg, 11 mmol) was added. The reaction solution was heated to 90 °C and stirred overnight. BIOLOGY EXAMPLES

[00702] The cell lines utilized in the high-content imaging assays, which include the NTR1-, NTR2-, and GPR35-U2OS osteosarcomas, were obtained from the laboratory of Dr. Lawrence Barak at the Duke University Medical Center. The media used in the culture of the cell lines, as well as the assays themselves, consisted of Minimum Essential Medium (15-010-CM) and L-glutamine (25-005-CL) from Cellgro/Mediatech (Manassas, VA), fetal bovine serum (SH30396.03) from Hyclone (Logan, UT), penicillin-streptomycin solution (PS-20) from Omega Scientific in Tarzana, CA, G418 (ant-gn-1) from Invivogen (San Diego, CA), and zeocin (R250-01) from Invitrogen (Carlsbad, CA). Cell lines were cultured in T225 tissue culture flasks (431082) supplied by Corning (Corning, NY). Additional reagents employed include Dulbecco's Phosphate-Buffered Saline (DPBS) (21-031CV) from Cellgro/Mediatech, Trypsin-EDTA 0.05% (25300) from Invitrogen, paraformaldehyde (30528954) from Acros Organics (Geel, Belgium), Hoechst 33342 (H3570) from Invitrogen. The high-content assays were run in 1536-well plates (29326) supplied by Aurora Biotechnology (Poway, CA) and utilized aluminum plate seals (T592100) from E&K Scientific (Santa Clara, CA).

[00703] The neurotensin 1 peptide (N6383) from Sigma-Aldrich (St. Louis, MO) was used as a positive control in the NTR1 primary HCS assay. For the NTR2 selectivity assay, the non-specific, small molecule 3-(4-fluorophenyl)-7,8-dimethoxy-5-(4-methylbenzyl)-5H-pyrazolo[4,3-c]quinolone which was synthesized internally was used as a positive control. The GPR35 selectivity screen utilized zaprinast (ALX430-020-M010) from Alexis Biochemicals (Farmingdale, NY) as a control.

[00704] The NTR1 β -Arrestin assays were performed using a PathHunterTM eXpress kit (93-0446E2) which contained the NTSR1 (NTR1) CHO cell line, OCC2 media (30-409), as well as the PathHunter Detection Reagents (93-0446E2). The kit was obtained from DiscoveRx (Fremont, CA). The assay employed the same neurotensin 1 peptide as a control as was used in the NTR1 primary assay. The assay was run in 1536-well, white, solid-bottom tissue culture plates (3727) from Corning.

[00705] The NTR1 Ca^{2+} Flux assay was performed by ChanTest (Rockville, MD). The assay used a CHO cell line, provided by ChanTest, which stably expressed the NTR1 receptor. The cells were grown and plated in Ham's F12 (11765) that was supplemented with fetal bovine serum (10437). Both were supplied by Gibco/Life Technologies (Carlsbad, CA). The DPBS (21-031CV) used in the assay was obtained from Cellgro/Mediatech and the G418 (ant-gn-1) was supplied by Invivogen. The Fluo-4 NW Dye (Invitrogen F36206) used to detect calcium mobilization was sourced by Invitrogen. The assay utilized 384-well, black, optical bottom assay plates (3683) and 384-well clear, non-binding plates (3640) as a compound source plate, both from Corning. The neurotensin 1 agonist control (1909) was obtained from Tocris (Bristol, U.K.).

NTR1 HTS

Primary Screen

[00706] The high-content imaging based NTR1 primary screen in 1536-well format was utilized to assay the MLSMR library of chemical entities in the following manner. On day one, 4 μL of a cell suspension containing 350,000 NTR1-U2OS cells per mL is added to each well of a 1536-well assay

plate. Cells are plated in MEM medium containing 2.5% Fetal Bovine Serum, 1% Penicillin/Streptomycin solution, 1% L-Glutamine, 400 ug/mL G418, and 200 ug/mL Zeocin. The assay plates are then incubated overnight at 37 °C, under 5% CO₂. Following the overnight incubation, a volume of 60 nL of the compounds at 2 mM in DMSO (final 20 µM, 1% DMSO) was transferred to columns 5-48 of the assay plates using a LabCyte Echo Liquid Handler. Next, 60 nL of DMSO were dispensed to columns 1-4, which served as the positive and neutral control wells. A volume of 2 µL of 300 nM neurotensin 1 (FAC = 100 nM) peptide dissolved in DPBS was added to the positive control wells of columns 1 and 2, and 2 uL of DPBS only was transferred to the neutral control wells of columns 3 and 4 using a Kalypsys liquid handler (Kalypsys Systems). The assay plates were centrifuged on an Eppendorf 5810 centrifuge at 1000 rpm for 1 min to ensure even liquid levels in the wells of the assay plates. The assay plates were then returned to the incubator for 1 hour. Following the hour-long incubation at 37 °C, the cells in each well were fixed with 4 uL of 6% paraformaldehyde added with a Multidrop Combi. The assay plates were centrifuged as before and incubated at room temperature for 1 hour. On the Kalypsys, plates were then aspirated down to 2.5 uL per well and washed twice with 11 uL per well of DPBS, followed by a final aspiration to 2.5 uL per well. On the Combi dispenser, 5 uL of 5 ug/mL Hoechst 33342 diluted in DPBS was added to each well of assay plates. The plates were again centrifuged as previously described, sealed, and incubated for at least 1 hour prior to being loaded on a PerkinElmer Opera QEHS.

[00707] Image acquisition was performed with a 45 plate capacity loader/stacker and the following settings: 40x 0.6 NA air objective, acquisition camera set to 2-by-2 binning for an image size of 688 by 512 pixels, beta-arrestin-GFP acquired using 488 nm laser excitation and 540/75 nm emission filters, DAPI (nuclei) using 365 nm Xenon lamp excitation and 450/50 nm emission filters, 3 fields per well. Image analysis was performed using the Acapella Spot Detection Algorithm. For analysis settings and the metrics employed in the data analyses, please refer to supplemental information.

[00708] Compounds were selected as hits if they exhibited a percent activity of greater than or equal to 40 when compared to the neurotensin 1 control in the “Ratio of Spot Intensity to Cytoplasmic Intensity” metric. Compounds were excluded from the hit set if the “CellCount” was less than or equal to 20 which was indicative of cellular toxicity.

NTR1 Single Concentration Hit Confirmation

[00709] Hits from the primary screen were ordered and received from the MLSMR as 10 mM solutions in DMSO. The hit confirmation assays were performed in an identical manner as the primary screen with the exception of the source plate compound concentration, and therefore the volume transferred to the assay plate to achieve the same concentration as in the primary screen. A volume of 12.5 nL of test compounds at 10 mM in DMSO (final 20 µM, 0.2% DMSO) was delivered. Compounds were screened in quadruplicate and those with an average activity with regards to the “Ratio of Spot Intensity to Cytoplasmic Intensity” metric of greater than or equal to 40% were identified as being “confirmed”.

NTR1 Dose Response

[00710] Compounds that were successfully confirmed in quadruplicate at 20 uM were then run in dose response in the primary assay. As with the single concentration hit confirmation, the assay was performed

in an identical manner as the primary screen with the following modifications. For the initial hit confirmation in dose response, 40, 20, 10, 5, and 2.5 nL of 6 mM and 188 uM test compound in DMSO were transferred from source well to assay wells to achieve the final assay concentrations ranging from 40 to 0.078 uM. Test compound wells and control wells were backfilled with DMSO to achieve a final volume of DMSO of 40 nL or a final assay concentration of 0.5%. EC₅₀ values for this assay and the following dose response assays were calculated in the CBIS database (Cheminnovation) using the same analysis parameters and metrics as in the primary assay. All subsequent dose response assays followed the same basic protocol.

NTR2 Dose Response

[00711] The operating procedure used for the NTR1 dose response assay was adapted to the development of the NTR2 assay which was used to assess receptor selectivity. The protocol put to use for the NTR2 dose response assays was identical to that used in the NTR1 dose response experiments with a few deviations. Firstly, the NTR2-U2OS cell line was used for the assay, but cell densities as well as cell media in the assay remained the same. Secondly, because the response of the NTR2 cell line to the neurotensin 1 peptide was low relative to the primary NTR1 cell line, a non-specific, small molecule 3-(4-fluorophenyl)-7,8-dimethoxy-5-(4-methylbenzyl)-5H-pyrazolo[4,3-c]quinoline was used at a saturating concentration of 10 uM to generate a more robust signal window.

GPR35 Dose Response

[00712] The GPR35 dose response assay was used to assess selectivity against an unrelated GPCR. It utilized a very similar protocol to the NTR1 and NTR2 dose response assays with a few modifications. The GPR35-U2OS cells were plated at the same density and in the same media as the other two assays. Zaprinast was added to control wells in the same volume and in the same manner as the NTR1 primary assay to yield a final concentration of 40 uM.

NTR1 β-Arrestin Dose Response

[00713] On day one of the assay, 5 uL of a cell suspension containing 120,000 NTSR1 (NTR1) CHO-K1 cells per mL in OCC2 media is added to each well of a 1536-well assay plate using a Multidrop Combi. The assay plates are then incubated for 48 hours at 37 °C, under 5% CO₂. Following the two day incubation, a volume of 20, 10, and 5 nL of 10 and 1.2 mM test compounds in DMSO were transferred from source wells to test compound wells in assay plates with a LabCyte Echo to achieve final assay concentrations ranging from 33 to 1.03 uM for each test sample. Test compound wells and control wells were backfilled with DMSO to achieve a final volume of DMSO of 20 nL or a final assay concentration of 0.33%. Next, 1 uL of 120 nM neurotensin 1 peptide (FAC = 20 nM) control diluted in assay media is dispensed with a Multidrop Combi to the positive control wells followed by 1 uL of assay media only to the neutral control and test compound wells. The assay plates were centrifuged on an Eppendorf 5810 centrifuge at 1000 rpm for 1 minute. The assay plates were then incubated in the dark at room temperature for 90 minutes. During the incubation, the detection reagent was prepared according to manufacturer's instructions. After 90 minutes, 3 uL of the detection reagent is delivered to all wells of each assay plate.

Plates are again centrifuged as previously described then incubated at room temperature for 1 hour before being read on the PerkinElmer using a luminescent protocol.

NTR1 Ca^{2+} Flux Dose Response

[00714] NTSR1 (NTR1) CHO cells are plated in 20 μL of assay media containing Ham's F12 supplemented with 10% fetal bovine serum and 0.4 mg/mL G418 at a concentration of 1.0×10^6 cells per mL into black, 384-well assay plates with clear bottoms using a Multidrop liquid handler. Assay plates are incubated at 37 °C in 5% CO_2 . The next day, the assay plates are aspirated to remove growth media and washed once with 20 μL of DPBS. The DPBS is then aspirated from the assay plate and replaced with 25 μL of Fluo-4 NW calcium dye prepared according to the manufacturer's recommendations then the plates are incubated for 1 hour at 37 °C. Following the incubation in the presence of dye, the assay is run on a Molecular Devices FlexStation-III using 494 excitation and 516 emission wavelengths set to read for 90 seconds with the addition at 18 seconds of 5 μL of 6X final concentration of test compounds and peptide control diluted in assay media containing 0.1% BSA and no more than 9% DMSO to yield a maximum final DMSO concentration of 1.5%. Percent activation is calculated based on the maximum response minus the minimum value over the time course relative to the neurotensin 1 control peptide at 100 pM. EC_{50} values were calculated for those compounds tested in 8-point dose dependent response.

[00715] Representative biological data is presented in Table 1.
