(54) Title: CLOTTING AND HEALING COMPOSITIONS CONTAINING KERATIN BIOMATERIALS

(57) Abstract: Disclosed are optimized keratin preparations for use in medical applications. Methods to produce optimized keratin preparations are provided for use in biomedical applications, particularly for the treatment of bleeding, and for the treatment of wounds. Also disclosed are surgical or paramedic aids comprising a substrate with keratin preparations provided thereon, and kits comprising keratin derivatives packaged in sterile form.
CLOTTING AND HEALING COMPOSITIONS CONTAINING KERATIN BIOMATERIALS

Mark E. Van Dyke

Related Applications

This application claims the benefit under 35 U.S.C. § 119(e) of United States Provisional Patent Application Serial Number 60/774,442, filed February 17, 2006, United States Provisional Patent Application Serial Number 60/774,587, filed February 17, 2006, and United States Provisional Patent Application Serial Number 60/774,920, filed February 17, 2006, the disclosures of each of which is incorporated herein by reference in its entirety.

This application is related to: Mark E. Van Dyke, U.S. Patent Application Serial No. 11/205,800, titled: Ambient Stored Blood Plasma Expanders, filed August 17, 2005; Mark E. Van Dyke, U.S. Patent Application titled: Nerve Regeneration Employing Keratin Biomaterials, filed February 9, 2007 (serial number to be assigned); and Mark E. Van Dyke, PCT Application, titled: Coatings and Biomedical Implants Formed from Keratin Biomaterials, filed February 16, 2007 (serial number to be assigned).

Government Support

This invention was made with Government support under contract number W81XWH-04-1-0105 from the United States Army. The U.S. Government has certain rights to this invention.

Field of the Invention

The present invention is generally related to keratin biomaterials and the use thereof in biomedical applications.

Background of the Invention

Rapid, voluminous hemorrhage instigates a cascade of events that are almost impossible to reverse without immediate and effective intervention. According to the Centers for Disease control, motor vehicle trauma is the leading cause of death for Americans under age 64, with more than 40,000 victims per year (National Vital Statistics System. National Center for Health Statistics. CDC (2003)). The number of people who die from motor vehicle-related injuries has not changed for the past 10 years. Historically, more than half of
those severely injured with concomitant hemorrhage die. While it has been shown that immediate intervention is the best method to limit patient mortality (Regel G et al., Acta Anaesthesiol Scand Suppl 1997;110:71-6), the methods for controlling bleeding in the prehospital setting have not substantively changed for centuries (Zimmerman LM and Veith I. Great ideas in the history of surgery. Norman Publishing, San Francisco, CA (1993)). Tourniquets and recent innovations in hemostatic pressure dressings have been effective for treatment of surface and extremity wounds, but there are few options for head, neck, chest, and abdominal hemorrhage.

On the battlefield, seventy percent of ballistic injuries result in death within the first hour. This is due primarily to the massive blood loss associated with penetrating trauma. In Vietnam, five thousand deaths resulted from bleeding from the extremities. It was estimated that twenty percent of these casualties could have been avoided with better first aid (Neel, S., "Medical Support of the U.S. Army in Vietnam 1965-1970," Department of the Army, Washington D.C. (1991)). Surprisingly, the percent of wounded who survive the first hour has not changed since the U.S. Civil War. In Iraq and Afghanistan, like in all previous wars, extremity wounds are the predominant injury. Deaths due to hemorrhage represents the majority of those killed in action in Iraq (Peake JB. N Engl J Med 2005;352(3):219-22).

Many products exist that effectively treat hemorrhage from the extremities (e.g. tourniquets and hemostatic pressure dressings) as well as those that work systemically. Numerous large animal preclinical and human clinical trials have been conducted and published, and many comparative investigations of hemostatic agents have been undertaken (Pusateri AE et al., J Trauma 2003;55(3):518-26; Alam HB et al., J Trauma 2003;54(6):1077-82; King K et al., Mil Med 2004;169(9):716-20). Coagulation adjuvants include mineral-based granules (e.g. QuikClot® hemostatic agent) (Turner SA et al., J Biomed Mater Res. 2002;63(1):37-47; Pusateri AE et al., J Trauma 2004;57(3):555-62; Robinson K, J Emerg Nurs 2004;30(2):160-1; Alam HB et al., J Trauma 2004;56(5):974-83), numerous dressings (Rothwell SW et al., Thromb Res 2003;108(5-6):335-40; Alencar de Queiroz AA et al., J Biomed Mat Res A 2003;64(1):147-54; Vournakis JN et al., J Surg Res 2003;113(1):1-5; Connolly RJ, J Trauma 2004;57(1 Suppl):S26-8; King DR et al., J Trauma 2004;57(4):756-9), clotting factors (Martinowitz U et al., J Trauma 2001;50(4):721-9; Schreiber MA et al., J Trauma 2002;53(2):252-9), and surgical approaches (Jaskille A et al., J Trauma 2005;59(6):1305-8; Takasu A et al., J Trauma 2004;56(5):984-90). Results have been mixed and are dependent on the model used. The zeolite-based QuikClot® hemostatic agent material has done well in some large animal trials, as has the chitosan-based bandage,
HemCon® hemostatic bandage. In one extensive comparative trial, fibrin dressings were clearly superior (Pusateri AE et al., J Trauma 2003;55(3):518-26). However, each of these hemostats has its challenges and limitations. QuikClot® hemostatic agent is known to produce localized heating which has been shown to damage tissue. Both HemCon® hemostatic bandage and QuikClot® hemostatic agent are not intended for internal injuries and must be removed from the wound site, and fibrin bandages are expensive and not yet approved by the Food and Drug Administration.

None of these materials, with the exception of a fibrin foam product that is still in development, can be applied without clear access to the site of hemorrhage, a major goal of first responders. Therefore there remains a great need for optimal materials that can control serious hemorrhage and promote wound healing.

The use of materials derived from keratin in medicine is not new. The earliest documented use of keratin in medicine comes from a Chinese herbalist named Li Shi-Zhen (Ben Cao Gang Mu. Materia Medica, a dictionary of Chinese herbs, written by Li Shi Zhen (1518-1593)). Over a 38-year period, he wrote a collection of 800 books known as the Ben Cao Gang Mu. These books were published in 1596, three years after his death. Among the more than 11,000 prescriptions described in these volumes, is a substance known as Xue Yu Tan, also known as Crinis Carbonisatus, that is made up of ground ash from pyrolyzed human hair. The stated indications for Xue Yu Tan were accelerated wound healing and blood clotting.

In the early 1800s, when proteins were still being called albuminoids (albumin was a well known protein at that time), many different kinds of proteins were being discovered. Around 1849, the word “keratin” appears in the literature to describe the material that made up hard tissues such as animal horns and hooves (keratin comes from the Greek “kera” meaning horn). This new protein intrigued scientists because it did not behave like other proteins. For example, the normal methods used for dissolving proteins were ineffective with keratin. Although methods such as burning and grinding had been known for some time, many scientists and inventors were more interested in dissolving hair and horns in order to make better products.

During the years from 1905 to 1935, many methods were developed to extract keratins using oxidative and reductive chemistries (Breinl F and Baudisch O, Z physiol Chem 1907;52:158-69; Neuberg C, U.S Pat. No. 926,999, July 6, 1909; Lissizin T, Biochem Bull 1915;4:18-23; Zdenko S, Z physiol Chem 1924;136:160-72; Lissizin T, Z physiol Chem 1928;173:309-11). By the late 1920s many techniques had been developed for breaking
down the structures of hair, horns, and hooves, but scientists were confused by the behavior of some of these purified proteins. Scientists soon concluded that many different forms of keratin were present in these extracts, and that the hair fiber must be a complex structure, not simply a strand of protein. In 1934, a key research paper was published that described different types of keratins, distinguished primarily by having different molecular weights (Goddard DR and Michaelis L, J Biol Chem 1934;106:605-14). This seminal paper demonstrated that there were many different keratin homologs, and that each played a different role in the structure and function of the hair follicle.

Earlier work at the University of Leeds and the Wool Industries Research Association in the United Kingdom had shown that wool and other fibers were made up of an outer cuticle and a central cortex. Building on this information, scientists at CSIRO conducted many of the most fundamental studies on the structure and composition of wool. Using X-ray diffraction and electron microscopy, combined with oxidative and reductive chemical methods, CSIRO produced the first complete diagram of a hair fiber (Rivett DE et al., “Keratin and Wool Research,” The Lennox Legacy, CSIRO Publishing; Collingwood, VIC, Australia; 1996).

In 1965, CSIRO scientist W. Gordon Crewther and his colleagues published the definitive text on the chemistry of keratins (Crewther WG et al., The Chemistry of Keratins. Anfinsen CB Jr et al., editors. Advances in Protein Chemistry 1965. Academic Press. New York:191-346). This chapter in Advances in Protein Chemistry contained references to more than 640 published studies on keratins. Once scientists knew how to extract keratins from hair fibers, purify and characterize them, the number of derivative materials that could be produced with keratins grew exponentially. In the decade beginning in 1970, methods to form extracted keratins into powders, films, gels, coatings, fibers, and foams were being developed and published by several research groups throughout the world (Anker CA, U.S. Pat. No. 3,642,498, February 15, 1972; Kawano Y and Okamoto S, Kagaku To Seibutsu 1975;13(5):291-223; Okamoto S, Nippon Shokuhin Kogyo Gakkaishi 1977;24(1):40-50). All of these methods made use of the oxidative and reductive chemistries developed decades earlier.

In 1982, Japanese scientists published the first study describing the use of a keratin coating on vascular grafts as a way to eliminate blood clotting (Noishiki Y et al., Kobunshi Ronbunshu 1982;39(4):221-7), as well as experiments on the biocompatibility of keratins (Ito H et al., Kobunshi Ronbunshu 1982;39(4):249-56). Soon thereafter in 1985, two researchers from the UK published a review article speculating on the prospect of using keratin as the

Taken together, the aforementioned body of published work is illustrative of the unique chemical, physical, and biological properties of keratins. However, there remains a great need for optimized keratin preparations for use in biomedical applications, particularly for the treatment of bleeding, and for the treatment of wounds.

**Summary of the Invention**

An aspect of the present invention is a pharmaceutical composition comprising a keratin derivative (e.g., keratose, kerateine, or a combination thereof) and optionally, at least one additional active ingredient.

Another aspect of the present invention is a method for treating bleeding in a subject afflicted with a bleeding wound comprising applying a positively charged composition to said wound in an amount effective to treat said bleeding. In some embodiments, said positively charged composition comprises, consists or consists essentially of derivatives of keratin, collagen, mucin, elastin, gelatin, fibronectin, vitronectin and laminin.

A further aspect of the present invention is a method for treating bleeding in a subject afflicted with a bleeding wound, comprising: applying a keratin derivative to the wound in an amount effective to treat the bleeding. In some embodiments, the keratin derivative comprises, consists of or consists essentially of alpha keratose, gamma keratose, acidic alpha keratose, basic alpha keratose, acidic gamma keratose, basic gamma keratose, alpha kerateine, gamma kerateine, acidic alpha kerateine, basic alpha kerateine, acidic gamma kerateine, basic gamma kerateine, or combinations thereof.

Yet another aspect of the present invention is a method of treating a wound in a subject in need thereof, comprising: topically applying a keratin derivative to the wound in an amount effective to treat the wound. In some embodiments the keratin derivative comprises, consists of or consists essentially of alpha keratose, gamma keratose, acidic alpha keratose, basic alpha keratose, acidic gamma keratose, basic gamma keratose, alpha kerateine, gamma kerateine, acidic alpha kerateine, basic alpha kerateine, acidic gamma kerateine, basic gamma kerateine, gamma
keratine, acidic alpha keratine, basic alpha keratine, acidic gamma keratine, basic gamma keratine, or combinations thereof.

Another aspect of the present invention is a surgical or paramedic aid, comprising: a solid, physiologically acceptable substrate; and a keratin derivative on the substrate. In some embodiments the keratin derivative comprises, consists of or consists essentially of alpha keratose, gamma keratose, acidic alpha keratose, basic alpha keratose, acidic gamma keratose, basic gamma keratose, alpha keratine, gamma keratine, acidic alpha keratine, basic alpha keratine, acidic gamma keratine, basic gamma keratine, or combinations thereof.

A still further aspect of the present invention is a kit comprising a keratin derivative and a container in which said keratin derivative is packaged in sterile form. In some embodiments the keratin derivative comprises, consists of or consists essentially of alpha keratose, gamma keratose, acidic alpha keratose, basic alpha keratose, acidic gamma keratose, basic gamma keratose, alpha keratine, gamma keratine, acidic alpha keratine, basic alpha keratine, acidic gamma keratine, basic gamma keratine, or combinations thereof.

Another aspect of the present invention is the use of a keratin derivative as described herein for the preparation of a composition or medicament for carrying out a method of treatment as described herein, or for making an article of manufacture as described herein.

**Brief Description of the Drawings**

**Figure 1. Kaplan-Mayer Survival Graph:** Time is presented in minutes on a logarithmic scale. All animals in the control group died within 60 minutes. One animal from the keratin and one from the HemCon® hemostatic bandage group was sacrificed upon recommendation of the animal care staff. Overall, keratin outperformed the other groups with only one death compared with 2 deaths in the QuikClot® hemostatic agent and HemCon® hemostatic bandage groups.

**Figure 2. Shed Blood:** Blood loss is normalized to body weight and expressed as percentage of body weight. Keratin and QuikClot® hemostatic agent groups lost significantly (*) less blood than the control and HemCon® hemostatic bandage groups.

**Figure 3. Mean Arterial Pressure (MAP):** Blood pressure is expressed in percentage of initial pressure. The negative control and QuikClot® hemostatic agent groups showed a steep drop in pressure to 40% of initial MAP. Animals treated with keratin or
HemCon® hemostatic bandage were able to stabilize the MAP around 80% of initial pressure. These differences were not statistically different compared to the control group.

**Figure 4. Shock Index (SI):** The modified shock index was calculated by dividing heart rate by MAP. This index is clinically used to assess the severity of a shock, with low values being better. The animals in the keratin group showed compensated low values over the entire study period, while QuikClot® hemostatic agent and HemCon® hemostatic bandage groups had similar values as the negative control. There was no statistical significance between the groups.

**Figure 5. Histological Assessment:** Representative tissue sections stained with hematoxylin and eosin, 50x. A) The negative control group shows signs of poor perfusion with wide and empty sinusoids. The surface is lacking a functional blood clot. B) The surface of the QuikClot® hemostatic agent treated samples shows an area of necrosis (arrow) and clotting. Only minimal cellular infiltration and tissue regeneration is visible. The void areas represent the removed QuikClot® hemostatic agent granules. C) Tissue samples from HemCon® hemostatic bandage treated animals showed patchy areas of adherent clotted blood, where there was a low level of cellular infiltration. D) Liver samples from animals treated with keratin show a thick layer of keratin biomaterial attached to the injured surface. There are signs of excellent biocompatibility with a high cellular activity and the formation of early granular tissue (large arrow) in the spaces between the keratin. Further, there is a high level of direct contact of hepatocytes with the keratin biomaterial (small arrow).

**Figure 6: Keratin Treated Group, High Magnification:** A) Formation of early granulation-like tissue within the spaces of the keratin gel, 200x. B) Interface between keratin gel and liver tissue showing integration of the biomaterial and tissue, and early cellular infiltration, 400x.

**Detailed Description of the Preferred Embodiments**

The disclosures of all United States patent references cited herein are to be incorporated herein by reference.

"Subjects" (or "patients") to be treated with the methods and compositions described herein include both human subjects and animal subjects (particularly other mammalian subjects such as dogs, cats, horses, monkeys, etc.) for veterinary purposes. Human subjects are particularly preferred. The subjects may be male or female and may be any age, including neonate, infant, juvenile, adolescent, adult, and geriatric subjects.
The ability of extracted keratin solutions to spontaneously self-assemble at the micron scale was published in two papers in 1986 and 1987 (Thomas H et al., Int J Biol Macromol 1986;8:258-64; van de Locht M, Melland Textilberichte 1987;10:780-6). This phenomenon is not surprising given the highly controlled superstructure whence hair keratins are obtained. When processed correctly, this ability to self-assemble can be preserved and used to create regular architectures on a size scale conducive to cellular infiltration. When keratins are hydrolyzed (e.g., with acids or bases), their molecular weight is reduced and they lose the ability to self-assemble. Therefore, processing conditions that minimize hydrolysis are preferred.

This ability to self-assemble is a particularly useful characteristic for tissue engineering scaffolds for two reasons. First, self-assembly results in a highly regular structure with reproducible architectures, dimensionality, and porosity. Second, the fact that these architectures form of their own accord under benign conditions allows for the incorporation of cells as the matrix is formed. These two features are critically important to any system that attempts to mimic the native extracellular matrix (ECM).

Cellular recognition is also an important characteristic of biomaterials that seek to mimic the ECM. Such recognition is facilitated by the binding of cell surface integrins to specific amino acid motifs presented by the constituent ECM proteins. Predominant proteins include collagen and fibronectin, both of which have been extensively studied with regard to cell binding. Both proteins contain several regions that support attachment by a wide variety of cell types. It has been shown that in addition to the widely know Arginine-Glycine-Aspartic Acid (RGD) motif, the "X"-Aspartic Acid-"Y" motif on fibronectin is also recognized by the integrin α4β1, where X equals Glycine, Leucine, or Glutamic Acid, and Y equals Serine or Valine. Keratin biomaterials derived from human hair contain these same binding motifs. A search of the NCBI protein database revealed sequences for 71 discrete, unique human hair keratin proteins. Of these, 55 are from the high molecular weight, low sulfur, alpha-helical family. This group of proteins is often referred to as the alpha-keratins and is responsible for imparting toughness to human hair fibers. These alpha-keratins have molecular weights greater than 40 kDa and an average cysteine (the main amino acid responsible for inter- and intramolecular protein bonding) content of 4.8 mole percent. Moreover, analysis of the amino acid sequences of these alpha keratin proteins showed that 78% contain at least one fibronectin-like integrin receptor binding motif, and 25% contain at least two or more. Two recent papers have highlighted the fact that these binding sites are likely present on the surface of keratin biomaterials by demonstrating excellent cell adhesion.

Other examples of natural polymers that may be utilized in a similar fashion to the disclosed keratin preparations include, but are not limited to, collagen, gelatin, fibronectin, vitronectin, laminin, fibrin, mucin, elastin, nidogen (entactin), proteoglycans, etc. (See, e.g., U.S. Pat. No. 5,691,203 to Katsuen et al.).

There are two theories for the biological activity of human hair extracts. The first is that the human hair keratins ("HHKs") themselves are biologically active. Over 70 human hair keratins are known and their cDNA-derived sequences published. However, the full compliment of HHKs is unknown and estimates of over 100 have been proposed (Gillespie JM, The structural proteins of hair: isolation characterization, and regulation of biosynthesis. Goldsmith LA (editor), Biochemistry and physiology of the skin (1983), Oxford University Press. New York;475-510). Within the complete range of HHKs are a small number that have been shown to participate in wound contracture and cell migration (Martin, P, Science 1997;276:75-81). In particular, keratins K-6 and K-16 are expressed in the epidermis during wound healing and are also found in the outer root sheath of the hair follicle (Bowden PE, Molecular Aspects of Dermatology (1993), John Wiley & Sons, Inc., Chichester:19-54). The presence of these HHKs in extracts of human hair, and their subsequent dosing directly into a wound bed, may be responsible for "shortcutting" the otherwise lengthy process of differentiation, migration, and proliferation, or for alleviating some biochemical deficiency, thereby accelerating the tissue repair and regeneration process.

It has been known for more than a decade that growth factors such as bone morphogenetic protein-4 (BMP-4) and other members of the transforming growth factor-β (TGF-β) superfamily are present in developing hair follicles (Jones CM et al., Development 1991;111:531-42; Lyons KM et al., Development 1990;109:833-44; Blessings M et al., Genes and Develop 1993;7:204-15). In fact, more than 30 growth factors and cytokines are involved in the growth of a cycling hair follicle (Hardy MH, Trends Genet 1992;8(2):55-61; Stenn KS et al., J Dermato Sci 1994;7S:S109-24; Rogers GE, Int J Dev Biol 2004;48(2-3):163-70). Many of these molecules have a pivotal role in the regeneration of a variety of tissues. It is highly probable that a number of growth factors become entrained within human hair when cytokines bind to stem cells residing in the bulge region of the hair follicle (Panteleyev AA et al., J Cell Sci 2001;114:3419-31). These growth factors would most certainly be extracted along with the keratins from end-cut human hair. This observation is not without precedent, as it has previously been shown that many different types of growth
factors are present in the extracts of various tissues, and that their activity is maintained even after chemical extraction. Observations such as these show mounting evidence that a number of growth factors may be present in end-cut human hair, and that the keratins may be acting as a highly effective delivery matrix of, inter alia, these growth factors.

Keratins are a family of proteins found in the hair, skin, and other tissues of vertebrates. Hair is a unique source of human keratins because it is one of the few human tissues that is readily available and inexpensive. Although other sources of keratins are acceptable feedstocks for the present invention, (e.g. wool, fur, horns, hooves, beaks, feathers, scales, and the like), human hair is preferred for use with human subjects because of its biocompatibility.

Keratins can be extracted from human hair fibers by oxidation or reduction using methods that have been published in the art (See, e.g., Crewther WG et al. The chemistry of keratins, in Advances in Protein Chemistry 1965;20:191-346). These methods typically employ a two-step process whereby the crosslinked structure of keratins is broken down by either oxidation or reduction. In these reactions, the disulfide bonds in cysteine amino acid residues are cleaved, rendering the keratins soluble (Scheme 1). The cuticle is essentially unaffected by this treatment, so the majority of the keratins remain trapped within the cuticle's protective structure. In order to extract these keratins, a second step using a denaturing solution must be employed. Alternatively, in the case of reduction reactions, these steps can be combined. Denaturing solutions known in the art include urea, transition metal hydroxides, surfactant solutions, and combinations thereof. Preferred methods use aqueous solutions of tris in concentrations between 0.1 and 1.0 M, and urea solutions between 0.1 and 10M, for oxidation and reduction reactions, respectively.
Scheme 1. General representations of (a) oxidation and (b) reduction of disulfide crosslinks in keratin. These reactions cleave the sulfur-sulfur bond in cystine residues, thereby destroying the superstructure and rendering the keratins soluble in the reaction media. The resultant fractions are keratose (a) and kerateine (b).

If one employs an oxidative treatment, the resulting keratins are referred to as "keratoses." If a reductive treatment is used, the resulting keratins are referred to as "kerateines" (See Scheme 1).

Crude extracts of keratins, regardless of redox state, can be further refined into "gamma" and "alpha" fractions, e.g., by isoelectric precipitation. High molecular weight keratins, or "alpha keratins," (alpha helical), are thought to derive from the microfibrillar regions of the hair follicle, and typically range in molecular weight from about 40-85 kiloDaltons. Low molecular weight keratins, or "gamma keratins," (globular), are thought to derive from the extracellular matrix regions of the hair follicle, and typically range in molecular weight from about 10-15 kiloDaltons. (See Crewther WG et al. The chemistry of keratins, in Advances in Protein Chemistry 1965;20:191-346)

Even though alpha and gamma keratins possess unique properties, the properties of subfamilies of both alpha and gamma keratins can only be revealed through more sophisticated means of purification. For example, keratins may be fractionated into "acidic" and "basic" protein fractions. A preferred method of fractionation is ion exchange chromatography. These fractions possess unique properties, such as their differential effects on blood cell aggregation (See Table 1 below; See also: U.S. Patent Application Publication No. 2006/0051732).
"Keratin derivative" as used herein refers to any keratin fractionation, derivative or mixture thereof, alone or in combination with other keratin derivatives or other ingredients, including but not limited to alpha keratose, gamma keratose, alpha kerateine, gamma kerateine, meta keratin, keratin intermediate filaments, and combinations thereof, including the acidic and basic constituents thereof unless specified otherwise, along with variations thereof that will be apparent to persons skilled in the art in view of the present disclosure. In some embodiments, the keratin derivative comprises, consists or consists essentially of a particular fraction or subfraction of keratin. The derivative may comprise, consist or consist essentially of at least 80, 90, 95 or 99 percent by weight of said fraction or subfraction (or more).

In some embodiments, the keratin derivative comprises, consists of, or consists essentially of acidic alpha keratose.

In some embodiments, the keratin derivative comprises, consists of or consists essentially of alpha keratose, where the alpha keratose comprises, consists of or consists essentially of at least 80, 90, 95 or 99 percent by weight of acidic alpha keratose (or more), and where the alpha keratose comprises, consists of or consists essentially of not more than 20, 10, 5 or 1 percent by weight of basic alpha keratose (or less).

In some embodiments, the keratin derivative comprises, consists of, or consists essentially of basic alpha keratose.

In some embodiments, the keratin derivative comprises, consists of or consists essentially of alpha keratose, where the alpha keratose comprises, consists of or consists essentially of at least 80, 90, 95 or 99 percent by weight of basic alpha keratose (or more), and where the alpha keratose comprises, consists of or consists essentially of not more than 20, 10, 5 or 1 percent by weight of acidic alpha keratose (or less).

In some embodiments, the keratin derivative comprises, consists of, or consists essentially of acidic alpha kerateine.

In some embodiments, the keratin derivative comprises, consists of or consists essentially of alpha kerateine, where the alpha kerateine comprises, consists of or consists essentially of at least 80, 90, 95 or 99 percent by weight of acidic alpha kerateine (or more), and where the alpha kerateine comprises, consists of or consists essentially of not more than 20, 10, 5 or 1 percent by weight of basic alpha kerateine (or less).

In some embodiments, the keratin derivative comprises, consists of, or consists essentially of basic alpha kerateine.
In some embodiments, the keratin derivative comprises, consists of or consists essentially of alpha keratine, where the alpha keratine comprises, consists of or consists essentially of at least 80, 90, 95 or 99 percent by weight of basic alpha keratine (or more), and where the alpha keratine comprises, consists of or consists essentially of not more than 20, 10, 5 or 1 percent by weight of acidic alpha keratine (or less).

In some embodiments, the keratin derivative comprises, consists of or consists essentially of unfractionated alpha-gamma-kerateines. In some embodiments, the keratin derivative comprises, consists of or consists essentially of acidic alpha-gamma-kerateines. In some embodiments, the keratin derivative comprises, consists of or consists essentially of basic alpha-gamma-kerateines.

In some embodiments, the keratin derivative comprises, consists of or consists essentially of unfractionated alpha-gamma-keratose. In some embodiments, the keratin derivative comprises, consists of or consists essentially of acidic alpha-gamma-keratose. In some embodiments, the keratin derivative comprises, consists of or consists essentially of basic alpha-gamma-keratose.

In some embodiments, the keratin derivative comprises, consists of or consists essentially of unfractionated beta-keratose (e.g., derived from cuticle). In some embodiments, the keratin derivative comprises, consists of or consists essentially of basic beta-keratose. In some embodiments, the keratin derivative comprises, consists of or consists essentially of acidic beta-keratose.

The basic alpha keratose is preferably produced by separating basic alpha keratose from a mixture comprising acidic and basic alpha keratose, e.g., by ion exchange chromatography, and optionally the basic alpha keratose has an average molecular weight of from 10 to 100 or 200 kiloDaltons. More preferably, the average molecular weight is from 30 or 40 to 90 or 100 kiloDaltons. Optionally but preferably the process further comprises the steps of re-dissolving said basic alpha-keratose in a denaturing and/or buffering solution, optionally in the presence of a chelating agent to complex trace metals, and then re-precipitating the basic alpha keratose from the denaturing solution. It will be appreciated that the composition preferably contains not more than 5, 2, 1, or 0.1 percent by weight of acidic alpha keratose, or less.

The acidic alpha keratose is preferably produced by a reciprocal of the foregoing technique: that is, by separating and retaining acidic alpha keratose from a mixture of acidic and basic alpha keratose, e.g., by ion exchange chromatography, and optionally the acidic alpha keratose has an average molecular weight of from 10 to 100 or 200 kiloDaltons. More
preferably, the average molecular weight is from 30 or 40 to 90 or 100 kiloDaltons. Optionally but preferably the process further comprises the steps of re-dissolving said acidic alpha-keratose in a denaturing solution and/or buffering solution, optionally in the presence of a chelating agent to complex trace metals, and then re-precipitating the basic alpha keratose from the denaturing solution. It will be appreciated that the composition preferably contains not more than 5, 2, 1, or 0.1 percent by weight of basic alpha keratose, or less.

Basic and acidic fractions of other keratoses can be prepared in like manner as described above for basic and acidic alpha keratose.

The basic alpha keratine is preferably produced by separating basic alpha keratine from a mixture of acidic and basic alpha keratine, e.g., by ion exchange chromatography, and optionally the basic alpha keratine has an average molecular weight of from 10 to 100 or 200 kiloDaltons. Optionally but preferably the process further comprises the steps of re-dissolving said basic alpha-keratine in a denaturing and/or buffering solution, optionally in the presence of a chelating agent to complex trace metals, and then re-precipitating the basic alpha keratine from the denaturing solution. It will be appreciated that the composition preferably contains not more than 5, 2, 1, or 0.1 percent by weight of acidic alpha keratine, or less.

The acidic alpha keratine is preferably produced by a reciprocal of the foregoing technique: that is, by separating and retaining acidic alpha keratine from a mixture of acidic and basic alpha keratine, e.g., by ion exchange chromatography, and optionally the acidic alpha keratine has an average molecular weight of from 10 to 100 or 200 kiloDaltons. More preferably, the average molecular weight is from 30 or 40 to 90 or 100 kiloDaltons. Optionally but preferably the process further comprises the steps of re-dissolving said acidic alpha-keratine in a denaturing and/or buffering solution), optionally in the presence of a chelating agent to complex trace metals, and then re-precipitating the basic alpha keratine from the denaturing solution. It will be appreciated that the composition preferably contains not more than 5, 2, 1, or 0.1 percent by weight of basic alpha keratine, or less.

Basic and acidic fractions of other kerateines can be prepared in like manner as described above for basic and acidic alpha keratine.

Keratin materials are derived from any suitable source including, but not limited to, wool and human hair. In one embodiment keratin is derived from end-cut human hair, obtained from barbershops and salons. The material is washed in hot water and mild detergent, dried, and extracted with a nonpolar organic solvent (typically hexane or ether) to remove residual oil prior to use.
**Keratoses.** Keratose fractions are obtained by any suitable technique. In one embodiment they are obtained using the method of Alexander and coworkers (P. Alexander et al., *Biochem. J.* 46, 27-32 (1950)). Basically, the hair is reacted with an aqueous solution of peracetic acid at concentrations of less than ten percent at room temperature for 24 hours. The solution is filtered and the alpha-keratose fraction precipitated by addition of mineral acid to a pH of approximately 4. The alpha-keratose is separated by filtration, washed with additional acid, followed by dehydration with alcohol, and then freeze dried. Increased purity can be achieved by redissolving the keratose in a denaturing solution such as 7M urea, aqueous ammonium hydroxide solution, or 20mM tris base buffer solution (e.g., Trizma® base), re-precipitating, re-dissolving, dialyzing against deionized water, and re-precipitating at pH 4.

A preferred method for the production of keratoses is by oxidation with hydrogen peroxide, peracetic acid, or performic acid. A most preferred oxidant is peracetic acid. Preferred concentrations range from 1 to 10 weight/volume percent (w/v %), the most preferred being approximately 2 w/v %. Those skilled in the art will recognize that slight modifications to the concentration can be made to effect varying degrees of oxidation, with concomitant alterations in reaction time, temperature, and liquid to solid ratio. It has also been discussed by Crewther et al. that performic acid offers the advantage of minimal peptide bond cleavage compared to peracetic acid. However, peractic acid offers the advantages of cost and availability. A preferred oxidation temperature is between 0 and 100 degrees Celsius (°C). A most preferred oxidation temperature is 37°C. A preferred oxidation time is between 0.5 and 24 hours. A most preferred oxidation time is 12 hours. A preferred liquid to solid ratio is from 5 to 100:1. A most preferred ratio is 20:1. After oxidation, the hair is rinsed free of residual oxidant using a copious amount of distilled water.

The keratoses can be extracted from the oxidized hair using an aqueous solution of a denaturing agent. Protein denaturants are well known in the art, but preferred solutions include urea, transition metal hydroxides (e.g. sodium and potassium hydroxide), ammonium hydroxide, and tris(hydroxymethyl)aminomethane (tris base). A preferred solution is Trizma® base (a brand of tris base) in the concentration range from 0.01 to 1M. A most preferred concentration is 0.1M. Those skilled in the art will recognize that slight modifications to the concentration can be made to effect varying degrees of extraction, with concomitant alterations in reaction time, temperature, and liquid to solid ratio. A preferred extraction temperature is between 0 and 100 degrees Celsius. A most preferred extraction temperature is 37°C. A preferred extraction time is between 0.5 and 24 hours. A most
preferred extraction time is 3 hours. A preferred liquid to solid ratio is from 5 to 100:1. A most preferred ratio is 40:1. Additional yield can be achieved with subsequent extractions with dilute solutions of tris base or deionized (DI) water. After extraction, the residual solids are removed from solution by centrifugation and/or filtration.

The crude extract can be isolated by first neutralizing the solution to a pH between 7.0 and 7.4. A most preferred pH is 7.4. Residual denaturing agent is removed by dialysis against DI water. Concentration of the dialysis retentate is followed by lyophilization or spray drying, resulting in a dry powder mixture of both gamma- and alpha-keratose. Alternately, alpha-keratose is isolated from the extract solution by dropwise addition of acid until the pH of the solution reaches approximately 4.2. Preferred acids include sulfuric, hydrochloric, and acetic. A most preferred acid is concentrated hydrochloric acid. Precipitation of the alpha fraction begins at around pH 6.0 and continues until approximately 4.2. Fractional precipitation can be utilized to isolate different ranges of protein with different isoelectric properties. Solid alpha-keratose can be recovered by centrifugation or filtration.

The alpha keratose can be further purified by re-dissolving the solids in a denaturing solution. The same denaturing solutions as those utilized for extraction can be used, however a preferred denaturing solution is tris base. Ethylene diamine tetraacetic acid (EDTA) can be added to complex and remove trace metals found in the hair. A preferred denaturing solution is 20 mM tris base with 20 mM EDTA or DI water with 20 mM EDTA. If the presence of trace metals is not detrimental to the intended application, the EDTA can be omitted. The alpha-keratose is re-precipitated from this solution by dropwise addition of hydrochloric acid to a final pH of approximately 4.2. Isolation of the solid is by centrifugation or filtration. This process can be repeated several times to further purify the alpha-keratose.

The gamma keratose fraction remains in solution at pH 4 and is isolated by addition to a water-miscible organic solvent such as alcohol, followed by filtration, dehydrated with additional alcohol, and freeze dried. Increased purity can be achieved by redissolving the keratose in a denaturing solution such as 7M urea, aqueous ammonium hydroxide solution, or 20mM tris buffer solution, reducing the pH to 4 by addition of a mineral acid, removing any solids that form, neutralizing the supernatant, re-precipitating the protein with alcohol, redissolving, dialyzing against deionized water, and reprecipitating by addition to alcohol. The amount of alcohol consumed in these steps can be minimized by first concentrating the keratose solution by distillation.
After removal of the alpha keratose, the concentration of gamma keratose from a
typical extraction solution is approximately 1-2%. The gamma keratose fraction can be
isolated by addition to a water-miscible non-solvent. To effect precipitation, the gamma-
keratose solution can be concentrated by evaporation of excess water. This solution can be
concentrated to approximately 10-20% by removal of 90% of the water. This can be done
using vacuum distillation or by falling film evaporation. After concentration, the gamma-
keratose solution is added dropwise to an excess of cold non-solvent. Suitable non-solvents
include ethanol, methanol, acetone, and the like. A most preferred non-solvent is ethanol. A
most preferred method is to concentrate the gamma keratose solution to approximately 10
w/v % protein and add it dropwise to an 8-fold excess of cold ethanol. The precipitated
gamma keratose can be isolated by centrifugation or filtration and dried. Suitable methods
for drying include freeze drying (lyophilization), air drying, vacuum drying, or spray drying.
A most preferred method is freeze drying.

Kerateines. Kerateine fractions can be obtained using a combination of the methods
of Bradbury and Chapman (J. Bradbury et al., *Aust. J. Biol. Sci.* 17, 960-72 (1964)) and
Goddard and Michaelis (D. Goddard et al., *J. Biol. Chem.* 106, 605-14 (1934)). Essentially,
the cuticle of the hair fibers is removed ultrasonically in order to avoid excessive hydrolysis
and allow efficient reduction of cortical disulfide bonds in a second step. The hair is placed
in a solution of dichloroacetic acid and subjected to treatment with an ultrasonic probe.
Further refinements of this method indicate that conditions using 80% dichloroacetic acid,
solid to liquid of 1:16, and an ultrasonic power of 180 Watts are optimal (H. Ando et al., *Sen'i
Gakkaishi* 31(3), T81-85 (1975)). Solid fragments are removed from solution by filtration,
rinsed and air dried, followed by sieving to isolate the hair fibers from removed cuticle cells.

In some embodiments, following ultrasonic removal of the cuticle, alpha- and gamma
kerateines are obtained by reaction of the denuded fibers with mercaptoethanol. Specifically,
a low hydrolysis method is used at acidic pH (E. Thompson et al., *Aust. J. Biol. Sci.* 15, 757-
68 (1962)). In a typical reaction, hair is extracted for 24 hours with 4M mercaptoethanol that
has been adjusted to pH 5 by addition of a small amount of potassium hydroxide in
deoxygenated water containing 0.02M acetate buffer and 0.001M surfactant.

The solution is filtered and the alpha kerateine fraction precipitated by addition of
mineral acid to a pH of approximately 4. The alpha kerateine is separated by filtration,
washed with additional acid, followed by dehydration with alcohol, and then dried under
vacuum. Increased purity is achieved by re-dissolving the kerateine in a denaturing solution
such as 7M urea, aqueous ammonium hydroxide solution, or 20mM tris buffer solution, re-
precipitating, re-dissolving, dialyzing against deionized water, and re-precipitating at pH 4.

The gamma kerateine fraction remains in solution at pH 4 and is isolated by addition
to a water-miscible organic solvent such as alcohol, followed by filtration, dehydrated with
additional alcohol, and dried under vacuum. Increased purity can be achieved by
redisolving the kerateine in a denaturing solution such as 7M urea, aqueous ammonium
hydroxide solution, or 20mM tris buffer solution, reducing the pH to 4 by addition of a
mineral acid, removing any solids that form, neutralizing the supernatant, re-precipitating the
protein with alcohol, re-dissolving, dialyzing against deionized water, and reprecipitating by
addition to alcohol. The amount of alcohol consumed in these steps can be minimized by
first concentrating the keratin solution by distillation.

In an alternate method, the kerateine fractions are obtained by reacting the hair with
an aqueous solution of sodium thioglycolate.

A preferred method for the production of keratelines is by reduction of the hair with
thioglycolic acid or beta-mercaptoethanol. A most preferred reductant is thioglycolic acid
(TGA). Preferred concentrations range from 1 to 10M, the most preferred being
approximately 1.0M. Those skilled in the art will recognize that slight modifications to the
concentration can be made to effect varying degrees of reduction, with concomitant
alterations in pH, reaction time, temperature, and liquid to solid ratio. A preferred pH is
between 9 and 11. A most preferred pH is 10.2. The pH of the reduction solution is altered
by addition of base. Preferred bases include transition metal hydroxides, sodium hydroxide,
and ammonium hydroxide. A most preferred base is sodium hydroxide. The pH adjustment
is effected by dropwise addition of a saturated solution of sodium hydroxide in water to the
reductant solution. A preferred reduction temperature is between 0 and 100°C. A most
preferred reduction temperature is 37°C. A preferred reduction time is between 0.5 and 24
hours. A most preferred reduction time is 12 hours. A preferred liquid to solid ratio is from
5 to 100:1. A most preferred ratio is 20:1. Unlike the previously described oxidation
reaction, reduction is carried out at basic pH. That being the case, keratins are highly soluble
in the reduction media and are expected to be extracted. The reduction solution is therefore
combined with the subsequent extraction solutions and processed accordingly.

Reduced keratins are not as hydrophilic as their oxidized counterparts. As such,
reduced hair fibers will not swell and split open as will oxidized hair, resulting in relatively
lower yields. Another factor affecting the kinetics of the reduction/extraction process is the
relative solubility of keratelines. The relative solubility rankings in water is gamma-
keratose>alpha-keratose>gamma-keratine>alpha-keratine from most to least soluble. Consequently, extraction yields from reduced hair fibers are not as high. This being the case, subsequent extractions are conducted with additional reductant plus denaturing agent solutions. Preferred solutions for subsequent extractions include TGA plus urea, TGA plus tri base, or TGA plus sodium hydroxide. After extraction, crude fractions of alpha- and gamma-keratine can be isolated using the procedures described for keratones. However, precipitates of gamma- and alpha-keratine re-form their cystine crosslinks upon exposure to oxygen. Precipitates must therefore be re-dissolved quickly to avoid insolubility during the purification stages, or precipitated in the absence of oxygen.

Residual reductant and denaturing agents can be removed from solution by dialysis. Typical dialysis conditions are 1 to 2% solution of keratines dialyzed against DI water for 24 to 72 hours. Those skilled in the art will recognize that other methods exist for the removal of low molecular weight contaminants in addition to dialysis (e.g. microfiltration, chromatography, and the like). The use of tri base is only required for initial solubilization of the keratines. Once dissolved, the keratines are stable in solution without the denaturing agent. Therefore, the denaturing agent can be removed without the resultant precipitation of keratines, so long as the pH remains at or above neutrality. The final concentration of keratines in these purified solutions can be adjusted by the addition/removal of water.

Regardless of the form of the keratin (i.e. keratose or keratines), several different approaches to further purification can be employed to keratin solutions. Care must be taken, however, to choose techniques that lend themselves to keratin's unique solubility characteristics. One of the most simple separation technologies is isoelectric precipitation. In this method, proteins of differing isoelectric point can be isolated by adjusting the pH of the solution and removing the precipitated material. In the case of keratins, both gamma- and alpha- forms are soluble at pH >6.0. As the pH falls below 6, however, alpha-keratins begin to precipitate. Keratin fractions can be isolated by stopping the precipitation at a given pH and separating the precipitate by centrifugation and/or filtration. At a pH of approximately 4.2, essentially all of the alpha-keratin will have been precipitated. These separate fractions can be re-dissolved in water at neutral pH, dialyzed, concentrated, and reduced to powders by lyophilization or spray drying. However, keratine fractions must be stored in the absence of oxygen or in dilute solution to avoid crosslinking.

Another general method for separating keratins is by chromatography. Several types of chromatography can be employed to fractionate keratin solutions including size exclusion or gel filtration chromatography, affinity chromatography, isoelectric focusing, gel
electrophoresis, ion exchange chromatography, and immunoaffinity chromatography. These techniques are well known in the art and are capable of separating compounds, including proteins, by the characteristics of molecular weight, chemical functionality, isoelectric point, charge, or interactions with specific antibodies, and can be used alone or in any combination to effect high degrees of separation and resulting purity.

A preferred purification method is ion exchange (IEx) chromatography. IEx chromatography is particularly suited to protein separation owing to the amphiphilic nature of proteins in general and keratins in particular. Depending on the starting pH of the solution, and the desired fraction slated for retention, either cationic or anionic IEx (ClEx or AIE, respectively) techniques can be used. For example, at a pH of 6 and above, both gamma- and alpha-keratins are soluble and above their isoelectric points. As such, they are anionic and can be bound to an anionic exchange resin. However, it has been discovered that a sub-
fraction of keratins does not bind to a weakly anionic exchange resin and instead passes through a column packed with such resin. A preferred solution for AIEEx chromatography is purified or fractionated keratin, isolated as described previously, in purified water at a concentration between 0 and 5 weight/volume %. A preferred concentration is between 0 and 4 w/v %. A most preferred concentration is approximately 2 w/v %. It is preferred to keep the ionic strength of said solution initially quite low to facilitate binding to the AIEEx column. This is achieved by using a minimal amount of acid to titrate a purified water solution of the keratin to between pH 6 and 7. A most preferred pH is 6. This solution can be loaded onto an AIEEx column such as DEAE-Sepharose® resin or Q-Sepharose® resin columns. A preferred column resin is DEAE-Sepharose® resin. The solution that passes through the column can be collected and further processed as described previously to isolate a fraction of acidic keratin powder.

In some embodiments the activity of the keratin matrix is enhanced by using an AIEEx column to produce the keratin to thereby promote cell adhesion. Without wishing to be bound to any particular theory, it is envisioned that the fraction that passes through an anionic column, i.e. acidic keratin, promotes cell adhesion.

Another fraction binds readily, and can be washed off the column using salting techniques known in the art. A preferred elution medium is sodium chloride solution. A preferred concentration of sodium chloride is between 0.1 and 2M. A most preferred concentration is 2M. The pH of the solution is preferred to be between 6 and 12. A most preferred pH is 12. In order to maintain stable pH during the elution process, a buffer salt can be added. A preferred buffer salt is Trizma® base. Those skilled in the art will recognize
that slight modifications to the salt concentration and pH can be made to effect the elution of keratin fractions with differing properties. It is also possible to use different salt concentrations and pH’s in sequence, or employ the use of salt and/or pH gradients to produce different fractions. Regardless of the approach taken, however, the column eluent can be collected and further processed as described previously to isolate fractions of basic keratin powders.

A complimentary procedure is also feasible using CIEx techniques. Namely, the keratin solution can be added to a cation exchange resin such as SP Sepharose® resin (strongly cationic) or CM Sepharose® resin (weakly cationic), and the basic fraction collected with the pass through. The retained acid keratin fraction can be isolated by salting as previously described.

*Meta Keratins.* Meta keratins are synthesized from both the alpha and gamma fractions of keratine using substantially the same procedures. Basically, the keratine is dissolved in a denaturing solution such as 7M urea, aqueous ammonium hydroxide solution, or 20mM tris buffer solution. Pure oxygen is bubbled through the solution to initiate oxidative coupling reactions of cysteine groups. The progress of the reaction is monitored by an increase in molecular weight as measured using SDS-PAGE. Oxygen is continually bubbled through the reaction solution until a doubling or tripling of molecular weight is achieved. The pH of the denaturing solution can be adjusted to neutrality to avoid hydrolysis of the proteins by addition of mineral acid.

*Keratin Intermediate Filaments.* IFs of human hair fibers are obtained using the method of Thomas and coworkers (H. Thomas et al., *Int. J. Biol. Macromol.* 8, 258-64 (1986)). This is essentially a chemical etching method that reacts away the keratin matrix that serves to “glue” the IFs in place, thereby leaving the IFs behind. In a typical extraction process, swelling of the cuticle and sulfitolysis of matrix proteins is achieved using 0.2M Na₂SO₃, 0.1M Na₂O₆S₄ in 8M urea and 0.1M tris-HCl buffer at pH 9. The extraction proceeds at room temperature for 24 hours. After concentrating, the dissolved matrix keratins and IFs are precipitated by addition of zinc acetate solution to a pH of approximately 6. The IFs are then separated from the matrix keratins by dialysis against 0.05M tetraborate solution. Increased purity is obtained by precipitating the dialyzed solution with zinc acetate, redissolving the IFs in sodium citrate, dialyzing against distilled water, and then freeze drying the sample.

Further discussion of keratin preparations are found in U.S. Patent Application Publication 2006/0051732 (Van Dyke), which is incorporated by reference herein.
**Compositions and formulations.** Dry powders may be formed of keratin derivatives as described above in accordance with known techniques such as freeze drying (lyophilization). In some embodiments, compositions of the invention may be produced by mixing such a dry powder composition form with an aqueous solution to produce a composition comprising an electrolyte solution having said keratin derivative solubilized therein. The mixing step can be carried out at any suitable temperature, typically room temperature, and can be carried out by any suitable technique such as stirring, shaking, agitation, etc. The salts and other constituent ingredients of the electrolyte solution (e.g., all ingredients except the keratin derivative and the water) may be contained entirely in the dry powder, entirely within the aqueous composition, or may be distributed between the dry powder and the aqueous composition. For example, in some embodiments, at least a portion of the constituents of the electrolyte solution are contained in the dry powder.

The formation of a matrix comprising keratin materials such as described above can be carried out in accordance with techniques long established in the field or variations thereof that will be apparent to those skilled in the art. In some embodiments, the keratin preparation is dried and rehydrated prior to use. See, e.g., U.S. Pat. Nos. 2,413,983 to Lustig et al., U.S. Pat. No. 2,236,921 to Schollkipp et al., and 3,464,825 to Anker. In preferred embodiments, the matrix, or hydrogel, is formed by re-hydration of the lyophilized material with a suitable solvent, such as water or phosphate buffered saline (PBS). The gel can be sterilized, e.g., by γ-irradiation (800 krad) using a Co60 source. Other suitable methods of forming keratin matrices include, but are not limited to, those found in U.S. Pat. Nos. 6,270,793 (Van Dyke et al.), 6,274,155 (Van Dyke et al.), 6,316,598 (Van Dyke et al.), 6,461,628 (Blanchard et al.), 6,544,548 (Siller-Jackson et al.), and 7,01,987 (Van Dyke).

In some composition embodiments, the keratin derivatives (particularly alpha and/or gamma kerateine and alpha and/or gamma keratose) have an average molecular weight of from about 10 to 70 or 85 or 100 kiloDaltons. Other keratin derivatives, particularly meta-keratins, may have higher average molecular weights, e.g., up to 200 or 300 kiloDaltons. In general, the keratin derivative (this term including combinations of derivatives) may be included in the composition in an amount of from about 0.1, 0.5 or 1 percent by weight up to 3, 4, 5, or 10 percent by weight. The composition when mixed preferably has a viscosity of about 1 or 1.5 to 4, 8, 10 or 20 centipoise. Viscosity at any concentration can be modulated by changing the ratio of alpha to gamma keratose.

The keratin derivative composition or formulation may optionally contain one or more active ingredients such as one or more growth factors, analgesics, antimicrobials,
additional coagulants, etc. (e.g., in an amount ranging from 0.000001 to 1 or 5 percent by weight of the composition that comprises the keratin derivative(s)), to facilitate growth or healing, provide pain relief, inhibit the growth of microbes such as bacteria, facilitate or inhibit coagulation, facilitate or inhibit cell or tissue adhesion, etc. Examples of suitable growth factors include, but are not limited to, nerve growth factor, vascular endothelial growth factor, fibronectin, fibrin, laminin, acidic and basic fibroblast growth factors, testosterone, ganglioside GM-1, catalase, insulin-like growth factor-I (IGF-I), platelet-derived growth factor (PDGF), neuronal growth factor galectin-1, and combinations thereof. See, e.g., US Patent No. 6,506,727 to Hansson et al. and US Patent No. 6,890,531 to Horie et al.

As used herein, "growth factors" include molecules that promote the regeneration, growth and survival of tissue. Growth factors that are used in some embodiments of the present invention may be those naturally found in keratin extracts, or may be in the form of an additive, added to the keratin extracts or formed keratin matrices. Examples of growth factors include, but are not limited to, nerve growth factor (NGF) and other neurotrophins, platelet-derived growth factor (PDGF), erythropoietin (EPO), thrombopoietin (TPO), myostatin (GDF-8), growth differentiation factor-9 (GDF9), basic fibroblast growth factor (bFGF or FGF2), epidermal growth factor (EGF), hepatocyte growth factor (HGF), granulocyte-colony stimulating factor (G-CSF), and granulocyte-macrophage colony stimulating factor (GM-CSF). There are many structurally and evolutionarily related proteins that make up large families of growth factors, and there are numerous growth factor families, e.g., the neurotrophins (NGF, BDNF, and NT3). The neurotrophins are a family of molecules that promote the growth and survival of, inter alia, nervous tissue. Examples of neurotrophins include, but are not limited to, nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF), neurotrophin 3 (NT-3), and neurotrophin 4 (NT-4). See U.S. Pat. Nos. 5,843,914 to Johnson, Jr. et al.; 5,488,099 to Persson et al.; 5,438,121 to Barde et al.; 5,235,043 to Collins et al.; and 6,005,081 to Burton et al.

For example, a growth factor can be added to the keratin matrix composition in an amount effective to promote the regeneration, growth and survival of various tissues. The growth factor is provided in concentrations ranging from 0.1 ng/mL to 1000 ng/mL. More preferably, growth factor is provided in concentrations ranging from 1 ng/mL to 100 ng/mL, and most preferably 10 ng/mL to 100 ng/mL. See U.S. Pat. No. 6,063,757 to Urso.

The composition is preferably sterile and non-pyrogenic. The composition may be provided preformed and aseptically packaged in a suitable container, such as a flexible polymeric bag or bottle, or a foil container, or may be provided as a kit of sterile dry powder.
in one container and sterile aqueous solution in a separate container for mixing just prior to use. When provided pre-formed and packaged in a sterile container, the composition preferably has a shelf life of at least 4 or 6 months (up to 2 or 3 years or more) at room temperature, prior to substantial loss of viscosity (e.g., more than 10 or 20 percent) and/or substantial precipitation of the keratin derivative (e.g., settling detectable upon visual inspection). The kit may contain a single unit dose of the active keratin derivative. A single unit dose may be 0.1 or 0.5 or 1, to 100 or 200 or 300 grams of the keratin derivative, or more, depending upon its intended use.

Other examples of natural polymers that may be utilized in a similar fashion to the disclosed keratin preparations include, but are not limited to, collagen, gelatin, fibronectin, vitronectin, laminin, fibrin, mucin, elastin, nidogen (entactin), proteoglycans, etc. (See, e.g., U.S. Pat. No. 5,691,203 to Katsuen et al.).

Clotting compositions and methods to control bleeding containing keratin biomaterials. One aspect of the present invention is a method for treating bleeding in a subject afflicted with a bleeding wound comprising: applying a keratin derivative to a bleeding wound in an amount effective to treat the bleeding. In some embodiments, the keratin derivative comprises, consists of or consists essentially of keratene, alpha kerateine, gamma keratene, acidic alpha kerateine, basic alpha keratene, or combinations thereof, such as described above. The bleeding may be that associated with, e.g., severe trauma producing rapid, voluminous hemorrhaging, including, but not limited to: surgery; penetrating trauma such as stabbing and gunshot wounds; motor vehicle trauma; and head, neck, chest and abdominal hemorrhaging; with or without clear access to the site of the hemorrhaging.

Many different compositions may comprise the hemostatic agent, including, but not limited to, keratin derivatives. Other examples of hemostatic agents include, but are not limited to, those comprising fibrin or fibrinogen, thrombin, factor XIII, calcium, chitosan (deacetylated poly-N-acetyl glucosamine), zeolite (oxides of silicon, aluminum, sodium, magnesium, and quartz), chitin (acylated poly-N-acetyl glucosamine), bovine clotting factors, non-zeolite mineral (e.g., hydrophobic polymers and potassium salts), and molecular sieve materials from plant sources (e.g. TraumaDEX™, Arista™ AH, etc., Medafor, Inc., Minneapolis, MN). It should be noted, however, that not all of these hemostatic agents are recommended for all types of bleeding treatments, and those skilled in the art should select hemostatic agents for use in the disclosed compositions and methods accordingly. For example, zeolite is intended only for external use.
Wound healing compositions containing keratin biomaterials and methods to promote healing. Another aspect of the present invention is a method of treating a wound (e.g., burns, abrasions, incisions, pressure sores, etc.) in a subject in need thereof, comprising: topically applying a keratin derivative to the wound in an amount effective to treat the wound. In some embodiments the keratin derivative comprises, consists of or consists essentially of keratose, alpha keratose, acidic alpha keratose, keratene, alpha keratene, acidic alpha keratene, etc., or combinations thereof, such as described above. The keratin derivative can be topically applied as a dry powder formulation or, in some embodiments, applied in an aqueous carrier.

The dose of the keratin material depends upon the particular disorder or wound, age and condition of the subject, route of administration, etc., and can be optimized in accordance with known techniques. In some embodiments, the dosage will be dose may be 0.1 or 0.5 or 1, to 100 or 200 or 300 grams of the keratin derivative, or more, depending upon its intended use.

Surgical or paramedic aids. Another aspect of the invention is a surgical or paramedic aid, comprising a solid, physiologically acceptable substrate and a keratin derivative on said substrate. "Substrate" includes sponges, packings, wound dressings (such as gauze or bandages), sutures, fabrics, and prosthetic devices.

Embodiments of the invention are further described in the following non-limiting examples.

Example 1: Keratin Derivatives/Fractions

Keratose fractions were obtained using a method based on that of Alexander and coworkers. However the method was substantially modified to minimize hydrolysis of peptide bonds. Briefly, 50 grams of clean, dry hair that was collected from a local barber shop was reacted with 1000 mL of an aqueous solution of 2 w/v % peracetic acid (PAA) at room temperature for 12 hr. The oxidized hair was recovered using a 500 micron sieve, rinsed with copious amounts of DI water, and the excess water removed. Keratoses were extracted from the oxidized hair fibers with 1000 mL of 100mM Trizma® base. After 3 hours, the hair was separated by sieve and the liquid neutralized by dropwise addition of hydrochloric acid (HCl). Additional keratoses were extracted from the remaining hair with two subsequent extractions using 1000 mL of 0.1M Trizma® base and 1000 mL of DI water, respectively. Each time the hair was separated by sieve and the liquid neutralized with HCl. All three extracts were combined, centrifuged, and any residual solid material removed by filtration. The combined extract was purified by tangential flow dialysis against DI water.
with a 1KDa nominal low molecular weight cutoff membrane. The solution was concentrated and lyophilized to produce a crude keratose powder.

Keratine fractions were obtained using a modification of the method described by Goddard and Michaelis. Briefly, the hair was reacted with an aqueous solution of 1M TGA at 37°C for 24 hours. The pH of the TGA solution had been adjusted to pH 10.2 by dropwise addition of saturated NaOH solution. The extract solution was filtered to remove the reduced hair fibers and retained. Additional keratin was extracted from the fibers by sequential extractions with 1000 mL of 100mM TGA at pH 10.2 for 24 hours, 1000 mL of 10mM TGA at pH 10.2 for 24 hours, and DI water at pH 10.2 for 24 hours. After each extraction, the solution was centrifuged, filtered, and added to the dialysis system. Eventually, all the extracts were combined and dialyzed against DI water with a 1KDa nominal low molecular weight cutoff membrane. The solution was concentrated, titrated to pH 7, and stored at approximately 5% total protein concentration at 4°C. Alternately, the concentrated solution could be lyophilized and stored frozen and under nitrogen.

Just prior to fractionation, keratose samples were re-dissolved in ultrapure water and titrated to pH 6 by addition of dilute HCl solution. Keratine samples were titrated to pH 6 by careful addition of dilute HCl solution as well. The samples were loaded onto a 200mL flash chromatography column containing either DEAE-Sepharose (weakly anionic) or Q-Sepharose (strongly anionic) exchange resin (50-100 mesh; Sigma-Aldrich, Milwaukee, WI) with gentle pressure and the flow through collected (acidic keratin). A small volume of 10 mM Trizma® base (approximately 200 mL) at pH 6 was used to completely wash through the sample. Basic keratin was eluted from the column with 100mM tris base plus 2M NaCl at pH 12. Each sample was separately neutralized and dialyzed against DI water using tangential flow dialysis with a LMWCO of 1KDa, concentrated by rotary evaporation, and freeze dried.

As previously described, a sample of alpha-keratose was produced, separated on a DEAE-Sepharose IEx column into acidic and basic fractions, dissolved in PBS, and the pH adjusted to 7.4. These solutions were prepared at 5 weight percent concentration and their RBC aggregation characteristics grossly evaluated with fresh whole human blood by mixing at a 1:1 ratio. Samples were taken after 20 minutes and evaluated by light microscopy. The ion exchange chromatography was highly effective at separating the aggregation phenomenon (data not shown). Basic alpha-keratose was essentially free from interactions with blood cells, while the acidic alpha-keratose caused excessive aggregation.

Samples of acidic and basic alpha-keratose, unfractonated alpha+gamma-kerateines, unfractonated alpha+gamma-keratose, and beta-keratose (derived from cuticle) were
prepared at approximately 4 w/v % and pH 7.4 in phosphate buffered saline (PBS). Samples were tested for viscosity and red blood cell (RBC) aggregation. These results are shown in Table 1:

Example 2: Animal Model

The hemostatic potential of keratin gel was evaluated in a modestly challenging animal model. The keratin gel comprised unfractionated keratine (alpha+gamma). Liver injuries are notoriously problematic as both the size of the liver and of the wound increase. This rabbit model can produce both profuse and lethal hemorrhage. Controlled liver transection was used as a means to establish a consistent set of conditions that would result in exsanguination in the absence of treatment (negative control), yet provide for the recovery of test animals when a conventional hemostat was applied (positive control). It should be noted that the hemostats used as positive controls in this study are indicated for topical wounds and require concomitant pressure; they were applied without compression in this study. This was done to avoid the confounding contribution compression would add as it was not used with the keratin gel.

A total of 16 New Zealand rabbits (3.7 kg average) were used in this study. The animals received a standardized liver injury that consisted of transection of approximately one third of the left central lobe and were then randomized into one of four groups. Four animals served as negative controls and received no treatment, four animals received treatment with QuikClot® hemostatic agent, four animals were treated with HemCon® hemostatic bandage, and four animals were treated with keratin gel. No resuscitation fluids were given and all animals were closely monitored during surgery. After one hour the surgical wound was closed and the animals transferred to the housing facility. All surviving
animals were sacrificed after 72 hours. At the time of sacrifice, liver tissue was retrieved for histological analysis.

**Example 3: Surgeries and Postoperative Treatment**

All procedures were performed in accordance with Wake Forest University’s Animal Care and Use Committee guidelines, which encompass regulatory and accreditation agencies’ guidelines. The animals were weighed immediately before surgery. All animals were sedated using a combination of Ketamine 10 mg/kg and Xylazine 4 mg/kg through an intramuscular injection, intubated and maintained on 2-3% Isoflurane for the remainder of the procedure. The animals were then placed in a supine position, shaved and connected to the monitoring devices. All animals were connected to ECG leads, pulse oximeter cuff on the tail, and an intra-esophageal probe for temperature monitoring. After sterile prepping and draping, the abdominal incision was performed and the liver exposed. Prior to the liver injury, the abdominal aorta of the animals was exposed and canulated using a 23 gauge needle connected to a pressure transducer (Lab-stat, ADInstruments Pty. Ltd. Castle Hill, Australia) which in turn was connected to a PowerLab® (ADInstruments) system for data acquisition. The mean arterial pressure (MAP) was recorded continuously throughout the procedure. All animals were monitored for several minutes and assured to be in a stable state prior to liver injury. The median lobe of the liver was used for the injury due to its ample size and easy accessibility.

Preliminary data during model development showed that a consistent liver injury cross sectional area could be created that resulted in death when left untreated, but that when treated with a control material could rescue the animal. A 2.0 cm² surface area ring was used to inflict a consistent sized injury to the liver by pulling the left central lobe through the ring and cutting immediately adjacent to the ring with a surgical blade. The MAP, temperature, heart rate, O₂ saturation, and shed blood were recorded throughout the procedure at 30 seconds, 5, 15, 30, 45 and 60 minutes. Shed blood was measured at each time point using preweighed sterile surgical gauze which was placed under the liver injury. In addition, blood samples were taken for CBC through an ear vein.

All animals were randomized into the previously mentioned four experimental groups. The negative control group did not receive any treatment and the time of death was recorded in minutes after infliction of the injury. As for the other experimental groups, the treatment was administered at the 5 minute time point unless the MAP fell to half of the starting value. For standardization, the hemostatic materials applied were measured or
weighed. The keratin gel does not require compression so no compression was used in any of the other treatment groups so as not to confound the results. In the HemCon® hemostatic bandage treatment group, a 4.5 x 2.5 cm piece of bandage that was placed on the bleeding surface of the liver throughout the procedure and was removed prior to closure. In the QuikClot® hemostatic agent treated group, 2.5 grams of autoclave sterilized material per animal was used. The material was spread on the bleeding surface and was left after closure in the surviving animals. In the case of the keratin treatment group, 2 ml of the gel was used per animal. Sterile keratin gel was applied to the bleeding surface through a 1 ml syringe.

The keratin was also left in place after closure of the animals. These parameters were determined during initial model development based on complete coverage of the wound site. For the surviving animals, the monitoring continued for 60 minutes, after which the animal was considered to have survived the initial trauma and the bleeding stopped. The animals that were treated with HemCon® hemostatic bandage had to undergo removal of the material since it could not be left intraabdominally as indicated by the manufacturer. The aortic cannula was removed and hemostasis established at the insertion site. No aortic bleeding was observed in any animal at necropsy. The fascia and skin of the abdomen was closed in two layers. After complete closure of the abdomen, the animals were allowed to recover and transported to the housing facility where they were monitored every 15 minutes until complete recovery from anesthesia, then three times per day thereafter for the following three days. Blood samples were taken from all surviving animals every day for CBC analysis. Upon sacrifice at the 72 hour time point, the liver of each animal was harvested for histological evaluation.

All presented data is expressed as averages and the corresponding standard deviations. For statistical analysis, SPSS v.11 (SPSS Inc, Chicago, IL) was used. Outliers were defined as having a z-score larger then +3.0 or smaller then -3.0 using a modified z-score (median of the absolute deviation). Data at all time points were analyzed by one-way analysis of variance (ANOVA). If significant F values were found, the groups were further analyzed by Fischer’s Least Significant Difference Test (LSD). An alpha of p<0.05 was considered significant. The probability of a Type I error was minimized by limiting comparisons; only negative control versus the 3 treatment groups were performed. In order to compensate for bias generated by early drop out of dead animals (i.e. animals that exsanguinated before the end of the 60 minute operative period), polynomial regression to known pathologic endpoints was used to estimate values during the first 60 minutes. For the percent blood loss graphical data (Figure
2) where statistical relevance was reached with some groups, values are expressed as means with their corresponding standard error.

Negative control animals (i.e. no treatment), as expected, exsanguinated within the 60 minute operative period (31 ± 19 minutes). Two animals in the QuikClot® hemostatic agent group and one in the HemCon® hemostatic bandage group did not survive beyond the initial 60 minute operative period. Also in the HemCon® hemostatic bandage group, one animal was euthanized 24 hours post-op on the advice of the veterinary staff. This animal was not ambulatory and could not eat or drink. One animal in the keratin group was also sacrificed at 48 hours. Although the animal was moving freely in its cage, it was not eating or drinking. At necropsy, these animals showed no evidence of additional bleeding after the operative period. All other surviving animals recovered without incident, were freely moving in their cages within 24 hours, and had normal CBC by 72 hours (data not shown). A summary of the survival data is shown in Figure 1.

Mean Arterial Pressure. The mean arterial pressure (MAP) was recorded using a 23 gauge needle placed into the lower part of the abdominal aorta. The needle was connected to a PE 50 tube, which in turn was connected to a pressure transducer (Lab-stat) that was connected to a PowerLab system for pressure recording. The MAP was continuously monitored during the entire course of the procedure or until the death of the animal. To further evaluate the significance of a change in MAP and heart rate, shock index was used. Shock index is a well established clinical scoring system for fast assessment of trauma patients. The modified shock index was calculated by dividing heart rate by MAP (mmHg).

The mean arterial pressure in the abdominal aorta was recorded for 60 minutes. Animals in the keratin and HemCon® hemostatic bandage group were able to achieve stable MAPs after 5 minutes at 75% of the starting value. The QuikClot® hemostatic agent and control groups failed to stabilize MAP and dropped to 45% of the starting value after 60 minutes (Figure 3). However, these data did not reach statistical significance between groups.

The shock index (SI), a predictive score grading system for the severity of blood loss, showed a beneficial outcome for the keratin group with low values throughout the first 60 minutes (Figure 4). The high values of QuikClot® hemostatic agent matched with two early deaths during the first 20 minutes of observation supporting the predictive nature of this measure. Although a trend was noted, these data did not reach statistical significance in the present study.
Temperature, ECG and Heart Rate. The central temperature was recorded with an esophageal probe connected to the surgery room monitor. The temperature of the animal was continuously monitored throughout the procedure and recorded at the previously mentioned time points. The ECG and heart rate were monitored using a three lead system connected to the surgery room monitor and was maintained throughout the entire procedure. Flat line or irregular electrical activity with electrical mechanical dissociation was used to define the time of death.

The liver damage model employed in this study represented severe trauma with significant, rapid blood loss. The liver transection produced a lethal injury, typically involving one or two large vessels of approximately 1mm diameter and several in the 0.5 to 1.0 mm diameter ranges. The severity of the injury was such that untreated rabbits all exsanguinated within the 60 minute operative period. None of the animals were able to compensate for loss of blood volume with an increase in heart rate. All animals showed a comparable decrease from 263 bpm to 188 bpm after 30 minutes and 154 bpm after one hour. There were no statistically significance differences between the groups. However, the keratin group showed a trend toward compensation and recovery with an increase in heart rate in the second half of the surgical period from 30 min to 60 min. The temperature of all animals dropped in a similar fashion with a step drop of 0.8°C in the first 5 minutes and a total of 2.7°C over 60 minutes. There was no statistically significant difference between the experimental groups.

Shed Blood. Shed blood was measured by weight after subtracting the weight of the pre-weighed gauze. Weights were recorded at each time point and fresh gauze placed under the liver injury. The shed blood was represented as a percent of the original body weight for each animal. CBC was determined from samples taken from an ear vein on a HEMAVet® multi-species hematology system (Model 950FS, Drew Scientific, Dallas, TX).

Blood loss was measured by weighing the surgical gauze placed below the injured liver lobe. The blood loss was expressed as percentage of starting body weight. As expected in uncontrolled hemorrhage studies, all animals showed an initial phase of profuse bleeding followed by a linear phase with a lower bleeding rate, as MAP falls (Figure 2). A comparison of the keratin and QuikClot® hemostatic agent groups to the negative controls shows a significantly decreased amount of blood loss at the 30, 45, and 60 minute time points (p values for keratin vs. negative control were 0.018, 0.011 and 0.007; p values for QuikClot® hemostatic agent vs. negative control were 0.009, 0.005 and 0.004, respectively).
As one would expect, the survivability of the animals appeared to be dependent on the vascular anatomy at the injury site, which was not consistent from animal to animal even though the total surface area transected was controlled. When a single very large bleeder (> 1 mm), or multiple large bleeders (> 2 to 3 in the 1m size range) were encountered within the injury area, the animal’s chance of survival was negligible in the QuikClot® hemostatic agent and HemCon® hemostatic bandage groups. In the QuikClot® hemostatic agent group in particular, a single very large bleeder or an excess of 2 to 3 large bleeders would ensure lethality. It should be noted however, that when used according to manufacturer’s instructions with concomitant pressure, other studies have shown better survival rates using QuikClot® hemostatic agent and HemCon® hemostatic bandage. In all cases of treatment with keratin gel, which was also used without any compression, the animals survived for at least 24 hours, regardless of the size of the severed vessels. Although a small number of animals were used in all test groups (n=4), these outcomes are encouraging.

The keratin hemostatic gel consistently performed well by each outcome measure, particularly shed blood volume, MAP, and (importantly) survival. One particularly distinguishing outcome was shock index. In most cases of hemorrhage, cardiac output is increased to compensate for the drop in blood pressure. Once this mechanism takes over, the value of shock index increases rapidly and survivability becomes doubtful. Remarkably, the shock index in the keratin treatment group remained the lowest of all the materials tested, consistent with early effective hemostasis.

**Example 4: Histology**

A tissue sample including the damaged liver surface was removed from each animal within one hour of euthanasia. Each sample was placed in Tissue-Tek® O.C.T. Compound 4583 (Sakura®) and frozen in liquid nitrogen. The frozen blocks were sectioned into 8 μm slices using a cryostat (Model CM 1850, Leica Microsystems, Bannockburn, IL) to include the transected portion of the liver and mounted onto microscope slides. The slides were fixed and stained with Hematoxylin and Eosin (H&E). Technical difficulties in sectioning arose with both the QuikClot® hemostatic agent and the HemCon® hemostatic bandage sections. The brittle QuikClot® hemostatic agent made level sectioning difficult and created voids in the sections. The HemCon® hemostatic bandage bandage was removed before abdominal closure and therefore the clotted blood was only partially visible. Digital images were taken (Zeiss Axio Imager M1 Microscope, Carl Zeiss, Thornwood, NY) at varying magnifications to observe the interactions between the hemostat and the damaged area of the liver.
magnification of 100X showed the overall response of the tissue, while magnifications of 200X and 400X were used to visualize the cellular response.

The transected liver surfaces were examined by light microscopy of H&E stained sections. The negative control group showed a clean cut with no tissue response or necrosis (Figure 5A). Moreover, no functional clotting was observed with little thrombus adhered to the surface. The QuikClot® hemostatic agent samples were difficult to process due to the presence of this hard, granular zeolite in the clot. Histology revealed necrotic tissue mixed with blood clots (Figure 5B). The transparent areas represent QuikClot® hemostatic agent particles removed during processing. The HemCon® hemostatic bandage group showed some areas with clotted blood and adjacent cellular infiltration (Figure 5C). Since the HemCon® hemostatic bandage was removed after 60 minutes, most of the liver surfaces had only a thin layer of blood clots. The keratin group showed a thick layer of biomaterial attached to the damaged liver surface (Figure 5D). Granulation-like tissue with cellular infiltration had formed in the pores of the keratin biomaterial gel (Figure 6).

The keratin hemostatic gel was adherent to the tissue and hydrophilic. When deposited onto the bleeding surface of the liver it was sufficiently adhesive to not be washed away, even in the presence of profuse bleeding. The gel absorbed fluid from the blood and became even more adherent within a few minutes of administration. Clotting and adherence was almost instantaneous with contact. Interestingly, the keratin gel formed a thick seal of granulation-like tissue over the wound site by 72 hours. Upon inspection of histological sections, 3 days after injury host cells could be seen infiltrating the gel. It is believed that the keratin gel used in these experiments serves two purposes. First, contact of the gel with whole blood instigates thrombus formation, probably through platelet activation or concentration of clotting factors. Second, the adherent gel forms a physical seal of the wound site and provides a porous scaffold for cell infiltration and granulation-like tissue formation, much like clotted blood.

The foregoing is illustrative of the present invention, and is not to be construed as limiting thereof. The invention is defined by the following claims, with equivalents of the claims to be included therein.
THAT WHICH IS CLAIMED IS:

1. A pharmaceutical composition comprising:
   a) a keratin derivative; and
   b) optionally, at least one additional active ingredient;
   wherein, said keratin derivative comprises keratose, kerateine, or a combination thereof.

2. The composition of claim 1, wherein said keratin derivative comprises kerateine.

3. The composition of claim 1, wherein said keratin derivative consists essentially of keratose, kerateine, or a combination thereof.

4. The composition of claim 1, wherein said keratin derivative consists essentially of kerateine.

5. The composition of claim 1, wherein said keratin derivative consists essentially of acidic kerateine.

6. The composition of claim 1, wherein said keratin derivative consists essentially of acidic alpha kerateine.

7. The composition of claim 1, wherein said keratin derivative consists essentially of acidic gamma kerateine.

8. The composition of claim 1, wherein said at least one additional active ingredient is selected from the group consisting of analgesics, antimicrobial agents, and additional coagulants.

9. The composition of claim 1, wherein said additional active ingredient is a coagulant is selected from the group consisting of zeolite-based coagulant and chitosan-based coagulant.
10. A method for treating bleeding in a subject afflicted with a bleeding wound comprising applying a positively charged composition to said wound in an amount effective to treat said bleeding.

11. The method of claim 10, wherein said positively charged composition is selected from the group consisting of derivatives comprising: keratin, collagen, mucin, elastin, gelatin, fibronectin, vitronectin and laminin.

12. A method for treating bleeding in a subject afflicted with a bleeding wound, comprising: applying a keratin derivative to said wound in an amount effective to treat said bleeding; wherein said keratin derivative consists essentially of keratose, kerateine, or combinations thereof.

13. The method of claim 12, wherein said keratin derivative consists essentially of a kerateine.

14. The method of claim 12, wherein said keratin derivative consists essentially of an alpha kerateine.

15. The method of claim 12, wherein said keratin derivative consists essentially of acidic alpha kerateine.

16. The method of claim 15, wherein said acidic alpha kerateine is produced by the process of fractionating a mixture comprising acidic and basic alpha kerateine by ion exchange chromatography.

17. The method of claim 12, wherein said keratin derivative consists essentially of basic alpha kerateine.

18. The method of claim 17, wherein said basic alpha kerateine is produced by the process of fractionating a mixture comprising acidic and basic alpha kerateine by ion exchange chromatography.

19. A method of treating a wound in a subject in need thereof, comprising:
topically applying a keratin derivative to said wound in an amount effective to treat said wound,

wherein said keratin derivative consists essentially of a keratose, a kerateine, or combinations thereof.

20. The method of claim 19, wherein said keratin derivative consists essentially of a kerateine.

21. The method of claim 19, wherein said keratin derivative consists essentially of an alpha keratose.

22. The method of claim 19, wherein said keratin derivative consists essentially of acidic alpha kerateine.

23. The method of claim 22, wherein said acidic alpha kerateine is produced by the process of fractionating a mixture comprising acidic and basic alpha kerateine by ion exchange chromatography.

24. The method of claim 19, wherein said keratin derivative consists essentially of a keratose.

25. The method of claim 19, wherein said keratin derivative consists essentially of an alpha keratose.

26. The method of claim 19, wherein said keratin derivative consists essentially of acidic alpha keratose.

27. The method of claim 26, wherein said acidic alpha keratose is produced by the process of fractionating a mixture comprising acidic and basic alpha keratose by ion exchange chromatography.

28. A surgical or paramedic aid, comprising:

a solid, physiologically acceptable substrate; and

a keratin derivative on said substrate
wherein said keratin derivative consists essentially of a keratose, a kerateine, or combinations thereof.

29. The surgical or paramedic aid according to claim 28, wherein said substrate is selected from the group consisting of sponges, packings, wound dressings, sutures, fabrics, and prosthetic devices.

30. The surgical or paramedic aid according to claim 28, wherein said surgical or paramedic aid is sterile, and wherein said surgical or paramedic aid is packaged in a sterile container.

31. The surgical or paramedic aid according to claim 28, wherein said keratin derivative consists essentially of a kerateine.

32. The surgical or paramedic aid according to claim 28, wherein said keratin derivative consists essentially of an alpha kerateine.

33. The surgical or paramedic aid according to claim 28, wherein said keratin derivative consists essentially of acidic alpha kerateine.

34. The surgical or paramedic aid according to claim 33, wherein said acidic alpha kerateine is produced by the process of fractionating a mixture comprising acidic and basic alpha kerateine by ion exchange chromatography.

35. The surgical or paramedic aid according to claim 28, wherein said keratin derivative consists essentially of a keratose.

36. The surgical or paramedic aid according to claim 28, wherein said keratin derivative consists essentially of an alpha keratose.

37. The surgical or paramedic aid according to claim 28, wherein said keratin derivative consists essentially of acidic alpha keratose.
38. The surgical or paramedic aid according to claim 28, wherein said acidic alpha keratose is produced by the process of fractionating a mixture comprising acidic and basic alpha keratose by ion exchange chromatography.

39. A kit comprising:
   a) a keratin derivative; and
   b) a container in which said keratin derivative is packaged in said container in sterile form, and wherein said keratin derivative comprises keratose, kerateine, or mixtures thereof.

40. The kit of claim 39, wherein said keratin derivative is provided in hydrated or dehydrated form.

41. The kit of claim 39, wherein said container comprises a foil container.

42. The kit of claim 39, wherein said container is vacuum-packed.

43. The kit of claim 39, wherein said keratin derivative comprises a single unit dose.

44. The kit of claim 39, wherein said keratin derivative comprises 0.5 to 200 grams of dehydrated keratose, kerateine, or mixtures thereof.

45. The kit of claim 39, wherein said keratin derivative comprises 0.5 to 200 milliliters of hydrated keratose, kerateine, or mixtures thereof.

46. The kit of claim 39, further comprising a physiologically acceptable substrate.

47. The kit of claim 46, wherein said substrate is sterile, and wherein said substrate is packaged in said container in sterile form.

48. The kit of claim 46, wherein said substrate is selected from the group consisting of sponges, packings, wound dressings, sutures, fabrics, and prosthetic devices.
