(54) Title: LIGHT EMITTING DEVICES HAVING CURRENT REDUCING STRUCTURES AND METHODS OF FORMING LIGHT EMITTING DEVICES HAVING CURRENT REDUCING STRUCTURES

Figure 1

(57) Abstract: A light emitting device includes a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer. A non-transparent feature, such as a wire bond pad, is on the p-type semiconductor layer or on the n-type semiconductor layer opposite the p-type semiconductor layer, and a reduced conductivity region is in the p-type semiconductor layer or the n-type semiconductor layer and is aligned with the non-transparent feature. The reduced conductivity region may extend from a surface of the p-type semiconductor layer opposite the n-type semiconductor layer towards the active region and/or from a surface of the n-type semiconductor layer opposite the p-type semiconductor layer towards the active region.

LIGHT EMITTING DEVICES HAVING CURRENT REDUCING STRUCTURES
AND METHODS OF FORMING LIGHT EMITTING DEVICES HAVING
CURRENT REDUCING STRUCTURES

RELATED APPLICATION

[0001] The present application is a continuation-in-part of United States Patent Application No. 11/881,814, filed on June 30, 2004, the disclosure of which is hereby incorporated by reference herein as if set forth in its entirety.

FIELD OF THE INVENTION

[0002] This invention relates to semiconductor light emitting devices and fabricating methods therefor.

BACKGROUND

[0003] Semiconductor light emitting devices, such as Light Emitting Diodes (LEDs) or laser diodes, are widely used for many applications. As is well known to those having skill in the art, a semiconductor light emitting device includes a semiconductor light emitting element having one or more semiconductor layers that are configured to emit coherent and/or incoherent light upon energization thereof. As is well known to those having skill in the art, a light emitting diode or laser diode, generally includes a diode region on a microelectronic substrate. The microelectronic substrate may be, for example, gallium arsenide, gallium phosphide, alloys thereof, silicon carbide and/or sapphire. Continued developments in LEDs have resulted in highly efficient and mechanically robust light sources that can cover the visible spectrum and beyond. These attributes, coupled with the potentially long service life of solid state devices, may enable a variety of new display applications, and may place LEDs in a position to compete with the well entrenched incandescent and fluorescent lamps.

[0004] Much development interest and commercial activity recently has focused on LEDs that are fabricated in or on silicon carbide, because these LEDs can emit radiation in the blue/green portions of the visible spectrum. See, for example,

U.S. Patent 5,416,342 to Edmond et al., entitled Blue Light-Emitting Diode With High External Quantum Efficiency, assigned to the assignee of the present application, the disclosure of which is hereby incorporated herein by reference in its entirety as if set forth fully herein. There also has been much interest in LEDs that include gallium nitride-based diode regions on silicon carbide substrates, because these devices also may emit light with high efficiency.

[0005] The efficiency of conventional LEDs may be limited by their inability to emit all of the light that is generated by their active region. When an LED is energized, light emitting from its active region (in all directions) may be prevented from exiting the LED by, for example, a non-transparent wire bond pad. Typically, in gallium nitride based LEDs, a current spreading contact layer is provided to improve the uniformity of carrier injection across the cross section of the light emitting device. Current is injected into the p-side of the LED through the bond pad and the p-type contact. Light generated in an active region of the device is proportional to the carrier injection. Thus, a substantially uniform photon emission across the active region may result from the use of a current spreading layer, such as a substantially transparent p-type contact layer. However, a wire bond pad is typically not a transparent structure and, therefore, photons emitted from the active region of the LED that are incident upon the wire bond pad may be absorbed by the wire bond pad. For example, in some instances approximately 70% of the light incident on the wire bond pad may be absorbed. Such photon absorption may reduce the amount of light that escapes from the LED and may decrease the efficiency of the LED.

SUMMARY

[0006] A light emitting device according to some embodiments of the invention includes a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer. A non-transparent feature is on the p-type semiconductor layer or on the n-type semiconductor layer opposite the p-type semiconductor layer, and a reduced conductivity region is in the p-type semiconductor layer and is aligned with the non-transparent feature. The reduced conductivity region extends from a surface of the p-type semiconductor layer opposite the n-type semiconductor layer towards the active region. The non-transparent region may include a wire bond pad, a passivation region, and/or a current spreading finger.

[0007] The light emitting device may further include a substrate including first and second opposing surfaces, and the n-type semiconductor may be on the first surface of the substrate and the wire bond pad may be on the second surface of the substrate opposite the n-type semiconductor layer.

[0008] The light emitting device may further include a metal stack on the surface of the p-type semiconductor layer. The metal stack may include an ohmic layer directly on the p-type semiconductor layer, a reflective layer on the ohmic layer, and a bonding layer on the reflective layer. The light emitting device may further include a barrier layer between the reflective layer and the bonding layer.

[0009] The reduced conductivity region may extend from the surface of the p-type semiconductor layer to/into/through the active region. The reduced conductivity region may extend through the p-type semiconductor layer, the active region and into or through the n-type semiconductor layer.

[0010] The wire bond pad may be in contact with the reduced conductivity region, and the light emitting device may further include an ohmic contact on the n-type semiconductor layer adjacent and in electrical contact with the wire bond pad.

[0011] The active region may include a Group III-nitride based active region. The reduced conductivity region may include an insulating region and/or a region that is not non-transparent. In some embodiments, the reduced conductivity region may include an implanted region. The reduced conductivity region may correspond to a region of damage at an interface between the metal stack and the p-type semiconductor layer. The region of damage may include a wet or dry etched region of the p-type semiconductor layer, a region of the p-type semiconductor layer exposed to a high energy plasma, a region of the p-type semiconductor layer exposed to H₂ and/or a region of the p-type semiconductor layer exposed to a high energy laser.

[0012] A light emitting device according to further embodiments of the invention includes a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer. The device includes a non-transparent feature on the n-type semiconductor layer opposite the p-type semiconductor layer, and a metal contact on a surface of the p-type semiconductor layer opposite the n-type semiconductor layer. The metal contact forms an ohmic contact to the p-type semiconductor layer in a region other than a reduced conductivity area of the surface of the p-type semiconductor layer that is aligned with the non-transparent feature. The non-

transparent region may include a wire bond pad, a passivation region, and/or a current spreading finger

[0013] The light emitting device may further include a reduced conductivity region in the p-type semiconductor layer and aligned with the non-transparent feature and the reduced conductivity area, and the reduced conductivity region may extend from the surface of the p-type semiconductor layer towards the active region.

[0014] The light emitting device may further include a reduced conductivity region in the n-type semiconductor layer and aligned with the non-transparent feature, the reduced conductivity region extending from a surface of the n-type semiconductor layer opposite the p-type semiconductor layer towards the active region.

[0015] The light emitting device may further include a non-ohmic contact on the surface of the p-type semiconductor layer. The non-ohmic contact may include a metal that does not form an ohmic contact with the p-type semiconductor layer and/or an insulator on the surface of the p-type semiconductor layer.

[0016] A light emitting device according to further embodiments of the invention includes a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer. The device further includes a wire bond pad on the n-type semiconductor layer opposite the p-type semiconductor layer, and a reduced conductivity region in the n-type semiconductor layer and aligned with the wire bond pad. The reduced conductivity region extends from a surface of the n-type semiconductor layer opposite the p-type semiconductor layer towards the active region. The device further includes an ohmic contact on the n-type semiconductor layer adjacent and in electrical contact with the wire bond pad.

[0017] The light emitting device may further include a metal stack on a surface of the p-type semiconductor layer opposite the n-type semiconductor layer. The metal stack may include an ohmic layer directly on the p-type semiconductor layer, a reflective layer on the ohmic layer, and a bonding layer on the reflective layer.

[0018] The reduced conductivity region may include a first reduced conductivity region, and the light emitting device may further include a second reduced conductivity region in the p-type semiconductor layer and aligned with the wire bond pad. The second reduced conductivity region may extend from a surface of the p-type semiconductor layer opposite the n-type semiconductor layer towards the active region.

[0019] The light emitting device may further include a metal contact on a surface of the p-type semiconductor layer opposite the n-type semiconductor layer. The metal contact forms an ohmic contact to the p-type semiconductor layer in a region other than a reduced conductivity area of the surface of the p-type semiconductor layer that is aligned with the wire bond pad.

[0020] Methods according to some embodiments of the invention include forming a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer, forming a non-transparent feature on the n-type semiconductor layer opposite the p-type semiconductor layer, and forming a reduced conductivity region in the p-type semiconductor layer and aligned with the non-transparent feature. The reduced conductivity region extends from a surface of the p-type semiconductor layer opposite the n-type semiconductor layer towards the active region.

[0021] Methods of forming a light emitting device according to further embodiments of the invention include forming a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer, forming a wire bond pad on the n-type semiconductor layer opposite the p-type semiconductor layer, and forming a metal contact on a surface of the p-type semiconductor layer opposite the n-type semiconductor layer. The metal contact forms an ohmic contact to the p-type semiconductor layer in a region other than a reduced conductivity area of the surface of the p-type semiconductor layer that is aligned with the wire bond pad.

[0022] A light emitting device according to further embodiments of the invention includes a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer. A bond pad is on the p-type semiconductor layer opposite the n-type semiconductor layer, and a reduced conductivity region is in the p-type semiconductor layer and aligned with the bond pad. The reduced conductivity region extends from a surface of the p-type semiconductor layer opposite the n-type semiconductor layer towards the active region.

[0023] The light emitting device may further include a reflector between the bondpad and the p-type semiconductor layer, and/or a current spreading finger on the p-type semiconductor layer, and the reduced conductivity region may further be aligned with the current spreading finger.

BRIEF DESCRIPTION OF THE DRAWINGS

[0024] **Figure 1** is a cross-sectional view illustrating semiconductor light emitting devices having a current blocking structure according to some embodiments of the present invention.

[0025] **Figures 2A and 2B** are cross-sectional views illustrating fabrication of semiconductor devices according to some embodiments of the present invention.

[0026] **Figures 3 through 11** are cross-sectional views of light emitting devices according to further embodiments of the present invention.

[0027] **Figures 12 and 13** are perspective views of light emitting devices according to some embodiments of the present invention.

DETAILED DESCRIPTION OF EMBODIMENTS OF THE INVENTION

[0028] The present invention now will be described more fully hereinafter with reference to the accompanying drawings, in which embodiments of the invention are shown. However, this invention should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art. In the drawings, the thickness of layers and regions are exaggerated for clarity. Like numbers refer to like elements throughout. As used herein the term "and/or" includes any and all combinations of one or more of the associated listed items.

[0029] The terminology used herein is for the purpose of describing particular embodiments only and is not intended to be limiting of the invention. As used herein, the singular forms "a", "an" and "the" are intended to include the plural forms as well, unless the context clearly indicates otherwise. It will be further understood that the terms "comprises" and/or "comprising," when used in this specification, specify the presence of stated features, integers, steps, operations, elements, and/or components, but do not preclude the presence or addition of one or more other features, integers, steps, operations, elements, components, and/or groups thereof.

[0030] It will be understood that when an element such as a layer, region or substrate is referred to as being "on" or extending "onto" another element, it can be directly on or extend directly onto the other element or intervening elements may also be present. In contrast, when an element is referred to as being "directly on" or

extending "directly onto" another element, there are no intervening elements present. It will also be understood that when an element is referred to as being "connected" or "coupled" to another element, it can be directly connected or coupled to the other element or intervening elements may be present. In contrast, when an element is referred to as being "directly connected" or "directly coupled" to another element, there are no intervening elements present. Like numbers refer to like elements throughout the specification.

[0031] It will be understood that, although the terms first, second, etc. may be used herein to describe various elements, components, regions, layers and/or sections, these elements, components, regions, layers and/or sections should not be limited by these terms. These terms are only used to distinguish one element, component, region, layer or section from another region, layer or section. Thus, a first element, component, region, layer or section discussed below could be termed a second element, component, region, layer or section without departing from the teachings of the present invention.

[0032] Furthermore, relative terms, such as "lower" or "bottom" and "upper" or "top," may be used herein to describe one element's relationship to another elements as illustrated in the Figures. It will be understood that relative terms are intended to encompass different orientations of the device in addition to the orientation depicted in the Figures. For example, if the device in the Figures is turned over, elements described as being on the "lower" side of other elements would then be oriented on "upper" sides of the other elements. The exemplary term "lower", can therefore, encompass both an orientation of "lower" and "upper," depending of the particular orientation of the figure. Similarly, if the device in one of the figures is turned over, elements described as "below" or "beneath" other elements would then be oriented "above" the other elements. The exemplary terms "below" or "beneath" can, therefore, encompass both an orientation of above and below.

[0033] Embodiments of the present invention are described herein with reference to cross-section illustrations that are schematic illustrations of idealized embodiments of the present invention. As such, variations from the shapes of the illustrations as a result, for example, of manufacturing techniques and/or tolerances, are to be expected. Thus, embodiments of the present invention should not be construed as limited to the particular shapes of regions illustrated herein but are to include deviations in shapes that result, for example, from manufacturing. For

example, an etched region illustrated or described as a rectangle will, typically, have rounded or curved features. Thus, the regions illustrated in the figures are schematic in nature and their shapes are not intended to illustrate the precise shape of a region of a device and are not intended to limit the scope of the present invention.

[0034] Unless otherwise defined, all terms (including technical and scientific terms) used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. It will be further understood that terms, such as those defined in commonly used dictionaries, should be interpreted as having a meaning that is consistent with their meaning in the context of this specification and the relevant art and will not be interpreted in an idealized or overly formal sense unless expressly so defined herein.

[0035] It will also be appreciated by those of skill in the art that references to a structure or feature that is disposed "adjacent" another feature may have portions that overlap or underlie the adjacent feature.

[0036] Although various embodiments of LEDs disclosed herein include a substrate, it will be understood by those skilled in the art that the crystalline epitaxial growth substrate on which the epitaxial layers comprising an LED are grown may be removed, and the freestanding epitaxial layers may be mounted on a substitute carrier substrate or submount which may have better thermal, electrical, structural and/or optical characteristics than the original substrate. The invention described herein is not limited to structures having crystalline epitaxial growth substrates and may be utilized in connection with structures in which the epitaxial layers have been removed from their original growth substrates and bonded to substitute carrier substrates.

[0037] Some embodiments of the present invention may provide for improved efficacy of a light emitting device by reducing and/or preventing current flow in an active region of the device in a region beneath a wire bond pad or other non-transparent structure. Thus, some embodiments of the present invention may provide light emitting devices and methods of fabricating light emitting devices having a current blocking mechanism below the wire bond pad. By reducing and/or preventing current from being injected directly beneath the wire bond pad, the current may be more likely to be converted to photon emission in areas of the device not under the wire bond pad. Thus, there may be a reduced probability of light being absorbed by the wire bond pad. In some embodiments of the present invention, an increase in

efficiency of a light emitting device according to some embodiments of the present invention may be proportional to the size of the wire bond pad.

[0038] Embodiments of the present invention may be particularly well suited for use in nitride-based light emitting devices such as Group III-nitride based devices. As used herein, the term "Group III nitride" refers to those semiconducting compounds formed between nitrogen and the elements in Group III of the periodic table, usually aluminum (Al), gallium (Ga), and/or indium (In). The term also refers to ternary and quaternary compounds such as AlGaN and AlInGaN. As is well understood by those in this art, the Group III elements can combine with nitrogen to form binary (*e.g.*, GaN), ternary (*e.g.*, AlGaN, AlInN), and quaternary (*e.g.*, AlInGaN) compounds. These compounds all have empirical formulas in which one mole of nitrogen is combined with a total of one mole of the Group III elements. Accordingly, formulas such as $\text{Al}_x\text{Ga}_{1-x}\text{N}$ where $0 \leq x \leq 1$ are often used to describe them. However, while embodiments of the present invention are described herein with reference to Group III-nitride based light emitting devices, such as gallium nitride based light emitting devices, certain embodiments of the present invention may be suitable for use in other semiconductor light emitting devices, such as for example, GaAs and/or GaP based devices.

[0039] Light emitting devices according to some embodiments of the present invention may include a light emitting diode, laser diode and/or other semiconductor device which includes one or more semiconductor layers, which may include silicon, silicon carbide, gallium nitride and/or other semiconductor materials, a substrate which may include sapphire, silicon, silicon carbide and/or other microelectronic substrates, and one or more contact layers which may include metal and/or other conductive layers. In some embodiments, ultraviolet, blue and/or green LEDs may be provided. The design and fabrication of semiconductor light emitting devices are well known to those having skill in the art and need not be described in detail herein.

[0040] For example, light emitting devices according to some embodiments of the present invention may include structures such as the gallium nitride-based LED and/or laser structures fabricated on a silicon carbide substrate such as those devices manufactured and sold by Cree, Inc. of Durham, North Carolina. The present invention may be suitable for use with LED and/or laser structures that provide active regions such as described in United States Patent Nos. 6,201,262; 6,187,606;

6,120,600; 5,912,477; 5,739,554; 5,631,190; 5,604,135; 5,523,589; 5,416,342; 5,393,993; 5,338,944; 5,210,051; 5,027,168; 5,027,168; 4,966,862 and/or 4,918,497, the disclosures of which are incorporated herein by reference as if set forth fully herein. Other suitable LED and/or laser structures are described in published U.S. Patent Publication No. US 2003/0006418 A1 entitled *Group III Nitride Based Light Emitting Diode Structures With a Quantum Well and Superlattice, Group III Nitride Based Quantum Well Structures and Group III Nitride Based Superlattice Structures*, published January 9, 2003, as well as published U.S. Patent Publication No. US 2002/0123164 A1 entitled *Light Emitting Diodes Including Modifications for Light Extraction and Manufacturing Methods Therefor*. Furthermore, phosphor coated LEDs, such as those described in U.S. Application Serial No. 10/659,241, entitled *Phosphor-Coated Light Emitting Diodes Including Tapered Sidewalls and Fabrication Methods Therefor*, filed September 9, 2003, the disclosure of which is incorporated by reference herein as if set forth fully, may also be suitable for use in embodiments of the present invention. The LEDs and/or lasers may be configured to operate such that light emission occurs through the substrate. In such embodiments, the substrate may be patterned so as to enhance light output of the devices as is described, for example, in the above-cited U.S. Patent Publication No. US 2002/0123164 A1. These structures may be modified as described herein to provide blocking structures according to some embodiments of the present invention.

[0041] Thus, for example, embodiments of the present invention may be utilized with light emitting devices having bond pads of differing shapes or sizes. The light emitting devices may be on differing substrates, such as silicon carbide, sapphire, gallium nitride, silicon or other substrate suitable substrate for providing Group III-nitride devices. The light emitting devices may be suitable for subsequent singulation and mounting on a suitable carrier. The light emitting devices may include, for example, single quantum well, multi-quantum well and/or bulk active region devices. Some embodiments of the present invention may be used with devices utilizing a tunneling contact on the p-side of the device.

[0042] **Figure 1** is a cross-sectional schematic illustration of a light emitting device according to some embodiments of the present invention. As seen in **Figure 1**, a substrate **10**, such as an n-type silicon carbide substrate, has an optional n-type semiconductor layer **12**, such as a gallium nitride based layer, provided thereon. The n-type semiconductor layer **12** may include multiple layers, for example, buffer layers

or the like. In some embodiments of the present invention, the n-type semiconductor layer 12 is provided as an AlGaN layer, that may be of uniform or gradient composition, and/or a GaN layer. The n-type semiconductor layer 12 may be doped, for example, with silicon, germanium and/or tellurium.

[0043] While described herein with reference to a silicon carbide substrate, in some embodiments of the present invention other substrate materials may be utilized. For example, a sapphire substrate, GaN or other substrate material may be utilized. In such a case, the contact 20 may be located, for example, in a recess that contacts the n-type semiconductor layer 12, so as to provide a second contact for the device. Other configurations may also be utilized.

[0044] An active region 14, such as a single or double heterostructure, quantum well, multi-quantum well or other such active region may be provided on the n-type semiconductor layer. As used herein, the term "active region" refers to a region of semiconductor material of a light emitting device, that may be one or more layers and/or portions thereof, where a substantial portion of the photons emitted by the device when in operation are generated by carrier recombination. In some embodiments of the present invention, the active region refers to a region where substantially all of the photons emitted by the device are generated by carrier recombination.

[0045] Also illustrated in **Figure 1** is an optional p-type semiconductor layer 16. The p-type semiconductor material layer 16 may, for example, be a gallium nitride based layer, such as a GaN layer. In particular embodiments of the present invention, the p-type semiconductor layer 16 includes magnesium doped GaN. The p-type semiconductor layer 16 may include one or multiple layers and may be of uniform or gradient composition. In some embodiments of the present invention, the p-type semiconductor layer 16 is part of the active region 14.

[0046] A first contact metal layer 18 of contact metal that provides an ohmic contact to the p-type semiconductor material layer 16 is also provided. In some embodiments, the first contact metal layer 18 may function as a current spreading layer. In particular embodiments of the present invention where the p-type semiconductor material layer 16 is GaN, the first contact metal layer 18 may include Pt, indium-tin-oxide (ITO) or another transparent material that can form an ohmic contact to p-type GaN. In certain embodiments of the present invention, the first contact metal layer 18 is light permeable and in some embodiments is substantially

transparent. In some embodiments, the first contact metal layer 18 may be a relatively thin layer of Pt. For example, the first contact metal layer 18 may be a layer of Pt that is about 15 Å thick. An optional reflective layer 23 may be provided on the first metal contact layer 18. A wire bond pad 22 or other light absorbing (or otherwise non-transparent) feature is provided on the first contact metal layer 18. In the embodiments illustrated in **Figure 1**, the wire bond pad 22 is provided on the reflective layer 23, so that the reflective layer 23 is between the wire bond pad 22 and the p-type semiconductor material layer 16. In some embodiments, a current spreading finger 154A (**Figure 13**) may be on the first contact metal layer 18.

[0047] A second contact metal layer 20 of contact metal that provides an ohmic contact to the n-type semiconductor material is also provided. The second contact metal layer 20 may be provided on a side of the substrate 10 opposite the active region 14. As discussed above, in some embodiments of the present invention the second contact metal layer may be provided on a portion of the n-type semiconductor material layer 12, for example, in a recess or at a base of a mesa including the active region. Furthermore, in some embodiments of the present invention, an optional back-side implant or additional epitaxial layers may be provided between the substrate 10 and the second contact metal layer 20.

[0048] As is further illustrated in **Figure 1**, a reduced conductivity region 30 is provided in the active region 14. The reduced conductivity region 30 may be positioned beneath light absorbing and/or non-transparent features and/or regions of the device. For example, as shown in **Figure 1**, the reduced conductivity region 30 may be positioned beneath the wire bond pad 22. A reduced conductivity region 30 may also be positioned beneath other features of the chip, such as passivation regions along an edge of the chip, current spreading fingers on a surface of the chip, or other features or areas of the chip that may tend to absorb light emitted by the chip.

[0049] In some embodiments of the present invention, the reduced conductivity region 30 extends through the active region 14. As used herein, reduced conductivity refers to a region with reduced current flow over other portions of the active region. In particular embodiments, the reduction is at least an order of magnitude and in some embodiments, substantially all current flow is blocked in the reduced conductivity region.

[0050] As noted above, in some embodiments of the present invention the reduced conductivity region 30 extends through the active region 14. In further

embodiments of the present invention, the reduced conductivity region 30 extends from the first contact metal layer 18 to the active region 14. In some embodiments, the reduced conductivity region extends from the first contact layer 18 into the active region 14. In some embodiments, the reduced conductivity region extends from the first contact layer 18 through the active region 14. The reduced conductivity region 30 may have substantially the same shape and/or area as the area of the wire bond pad 22 on the first contact metal layer 18. In some embodiments of the present invention, the reduced conductivity region 30 has a slightly larger area than the wire bond pad 22 while in other embodiments of the present invention, the reduced conductivity region 30 has a slightly smaller area than the wire bond pad 22. In certain embodiments of the present invention, the reduced conductivity region 30 does not absorb light or only absorbs a relatively small amount of light. In some embodiments of the present invention, the reduced conductivity region 30 is an insulating region.

[0051] The reduced conductivity region 30 may reduce and/or prevent current flow through the active region 14 in the area beneath the wire bond pad 22, so that carriers have a tendency to be injected in areas other than the reduced conductivity region 30. Thus, the presence of the reduced conductivity region 30 may reduce and/or prevent light generation through carrier recombination in this region. While not being bound by a particular theory of operation, this may be the case because the likelihood that a photon generated in the portion of the active region beneath the wire bond pad 22 is absorbed by the wire bond pad 22 may be higher than if the photon is generated in a portion of the active region that is not beneath the wire bond pad 22. By reducing and/or eliminating the light generated in the active region beneath the wire bond pad 22, the portion of the light generated by the light emitting device that is absorbed by the wire bond pad 22 may be reduced. For a given set of operating conditions, this reduction in the amount of light absorbed by the wire bond pad 22 may result in increased light extraction from the light emitting device as compared to a device operating under the same conditions where light is generated in the region beneath the wire bond pad 22. Thus, some embodiments of the present invention provide a reduced conductivity region 30 that extends into and, in some embodiments, through the active region 14 in the area beneath the wire bond pad 22. This may reduce the likelihood that carriers may spread and be injected into the active region 14 beneath the wire bond pad 22 and, thereby, result in photon generation in the area beneath the wire bond pad 22.

[0052] **Figures 2A and 2B** illustrate operations according to some embodiments of the present invention for forming light emitting devices having a reduced conductivity region as illustrated in **Figure 1**. As seen in **Figure 2A**, the various layers/regions of the light emitting device are fabricated. The particular operations in the fabrication of the light emitting device will depend on the structure to be fabricated and are described in the United States Patents and/or Applications incorporated by reference above and/or are well known to those of skill in the art and, therefore, need not be repeated herein. **Figure 2A** also illustrates formation of a mask **40** having a window **42** corresponding to the region where the wire bond pad **22** is to be formed.

[0053] An implant is performed using the mask **40** so as to implant atoms into the active region **14** in the region of the wire bond pad **22** so as to form the reduced conductivity region **30** as seen in **Figure 2B**. Such an implant may, for example, be a nitrogen implant. For example, for a gallium nitride based device, implant conditions of 60keV, $2 \times 10^{13} \text{ cm}^{-3} \text{ N}_2$ may produce a non-absorbing and insulating region in Mg doped GaN. The particular implant energy and/or atoms may depend on the structure in which the reduced conductivity region **30** is formed.

[0054] As seen in **Figure 2B**, after implantation, the wire bond pad **22** may be formed in the window **42**. In some embodiments, a reflective layer **23** may be formed in the window **42** prior to formation of the wire bond pad **22**. Thus, in some embodiments of the present invention, the wire bond pad **22** (and possibly the reflective layer **23**) and the reduced conductivity region **30** may be self-aligned. The wire bond pad **22** may be formed, for example, by forming a layer or layers of metal and then planarizing the layers to provide the wire bond pad **22**. The mask **40** may subsequently be removed. Optionally, the mask **40** may be made of an insulating material, such as SiO_2 and/or AlN, and may remain on the device as, for example, a passivation layer, or be removed.

[0055] **Figure 3** illustrates light emitting devices according to further embodiments of the present invention. In **Figure 3**, the first contact metal layer **18** includes a first portion **55** in contact with the p-type semiconductor material layer **16** that provides an ohmic contact to the p-type semiconductor material layer **16** and a second portion **57** in contact with the p-type semiconductor material layer **16** that does not form an ohmic contact to the p-type semiconductor material layer **16**. As used herein the term "ohmic contact" refers to a contact with a specific contact

resistivity of less than about $10 \text{ e}^{-03} \text{ ohm-cm}^2$ and, in some embodiments less than about $10 \text{ e}^{-04} \text{ ohm-cm}^2$. Thus, a contact that is rectifying or that has a high specific contact resistivity, for example, a specific contact resistivity of greater than about $10 \text{ e}^{-03} \text{ ohm-cm}^2$, is not an ohmic contact as that term is used herein.

[0056] The second portion 57 corresponds to the location of the wire bond pad 22. By not forming an ohmic contact, current injection into the p-type semiconductor material layer 16 in the portion 57 may be reduced and/or prevented. The portion 57 that does not form an ohmic contact may be provided by damaging the p-type semiconductor layer 16 and/or the first contact metal layer 18 in the region 50 beneath the wire bond pad 22.

[0057] For example, in gallium nitride based devices, the quality of the interface between the contact metal and the p-type semiconductor material may determine the quality of the resulting ohmic contact. Thus, for example, the p-type semiconductor material layer 16 in the region 50 may be exposed to a high energy plasma, such as Ar, to reduce p-type conductivity before formation of the first contact metal layer 18. Also, the p-type semiconductor material layer 16 and the first contact metal layer 18 in the region 50 may be exposed to a high energy plasma to damage the metal/GaN interface after formation of the first contact metal layer 18. The p-type semiconductor material 16 in the region 50 may be exposed to a H_2 while protecting the other regions of the p-type semiconductor material layer 16 before formation of the first contact metal layer 18. The p-type semiconductor material 16 in the region 50 may be wet or dry etched while protecting the other regions of the p-type semiconductor material layer 16 before formation of the first contact metal layer 18. Also, the p-type semiconductor material layer 16 in the region 50 may be exposed to a high energy laser while protecting the other regions of the p-type semiconductor material 16 before formation of the first contact metal layer 18.

[0058] Such selective damaging of the p-type semiconductor material layer 16 and/or metal layer 18 may be provided, for example, using a mask such as described above with reference to **Figures 2A and 2B** and/or by controlling a laser. The particular conditions utilized may vary depending on the procedure utilized and the composition of the p-type semiconductor material layer 16 and/or the first metal contact layer 18.

[0059] **Figure 4A** illustrates light emitting devices according to further embodiments of the present invention. In **Figure 4A**, a Schottky contact 60 is

provided on the p-type semiconductor material layer 16 and the first contact metal layer 18' formed on the p-type semiconductor material layer 16 and the Schottky contact 60. The wire bond pad 22 is provided on the portion of the first contact metal layer 18' on the Schottky contact 60. By forming a Schottky contact 60, current injection into the p-type semiconductor material layer 16 from the first contact metal layer 18' may be reduced and/or prevented in the region of the Schottky contact 60.

[0060] Alternatively, as shown in **Figure 4B**, a rectifying junction may be provided in the region below the wire bond pad 22. The rectifying junction may be provided, for example, by implanting the p-type semiconductor material layer 16 with n-type ions so as to convert the region 70 beneath the wire bond pad 22 to n-type semiconductor material. Such an implant may, for example, be carried out using a mask such as discussed above with reference to **Figures 2A** and **2B**. Alternatively, a region of n-type material could be formed where the Schottky contact 60 is illustrated in **Figure 4A** and the first contact metal 18' could be formed on the region of n-type semiconductor material and the p-type semiconductor material layer 16.

[0061] Referring to **Figure 5**, some embodiments of the invention provide a light emitting device 100A including a substrate 110 on which an n-type semiconductor layer 112, an active region 114 and a p-type semiconductor layer 116 are formed. The semiconductor substrate 110 may include a conductive silicon carbide substrate, for example, and the n-type semiconductor layer 112, the active region 114 and the p-type semiconductor layer 116 may include group III-nitride based semiconductor layers. The light emitting device 100A further includes a reduced conductivity region 130 in the p-type semiconductor layer 116. As seen in **Figure 5**, the substrate 110 may include shaped sidewalls 111 that may increase the efficiency of light extraction from the device 100A by changing the angle at which light generated in the active region 114 strikes the sidewalls of the device 100A. In the structure illustrated in **Figure 5**, the reduced conductivity region 130 may be located a distance D1 from the bond pad 122 of about 50 to 400 μm . The reduced conductivity region 130 may be formed using any of the methods described above, including implantation of ions into the p-type semiconductor layer 116.

[0062] The light emitting device 100A may be suitable for so-called "flip chip" mounting on an underlying support. In particular, the semiconductor structure may be mounted on a submount, bond pad or other surface with the p-type semiconductor layer 116 facing down and the substrate 110 facing up. In order to

facilitate bonding the light emitting device **100A** to a support, a p-contact metal stack **118** is formed on exposed surface of the type semiconductor layer **116**. Appropriate metal stacks for flip chip mounting of optoelectronic devices are disclosed for example in U.S. Patent Publication No. 2003/0015721 entitled "Light Emitting Diodes Including Modifications For Submount Bonding And Manufacturing Methods Therefor," the disclosure of which is incorporated herein by reference. In particular, the p-contact metal stack **118** may include an ohmic layer **118A** of a metal, such as platinum, that makes an ohmic contact with the p-type semiconductor layer **116**. The metal stack **118** may further include a reflective layer **118B**, a barrier layer **118C** and/or a bonding layer **118D**.

[0063] The bonding layer **118D** may include gold and/or tin, and may be provided to facilitate thermosonic and/or thermocompression bonding of the device **100A** to a submount. The reflective layer **118B** may include a reflective metal, such as silver or aluminum, and may be provided to reflect light away from a submount and back into the device **100A** so that it may be usefully extracted. The barrier layer **118C** may include a metal, such as tungsten, titanium, titanium nitride and/or nickel, that may prevent the metal of the bonding layer **118D** from contaminating the ohmic metal **118A** and /or the reflector **118B**. Barrier layers may be formed as described in U.S. Patent Publication No. 2005/0194603 entitled "Light Emitting Diodes Including Barrier Layers/Sublayers And Manufacturing Methods Therefor," the disclosure of which is incorporated herein by reference. An optional adhesion layer (not shown) may be provided between the barrier layer **118C** and the bonding layer **118D**.

[0064] When an optoelectronic device, such as the device **100A** shown in **Figure 5**, is mounted on an opaque support member with the p-side of the device **100A** facing down (i.e towards the support), it may not be necessary to form a transparent electrode or a current spreading layer on the exposed substrate **110**, since the conductivity of the substrate **110** may be high enough that current may spread naturally in the device. Accordingly, as shown in **Figure 5**, the device may include a wire bond pad **122** formed on the substrate **110**. An ohmic contact (not shown) may be formed between the wire bond pad **122** and the substrate **110**. In some embodiments, the ohmic contact may be formed in self-alignment with the bond pad **122**.

[0065] The reduced conductivity region **130** may extend from a surface of the p-type semiconductor layer **116** opposite the active region **114** into the p-type

semiconductor layer **116**. The reduced conductivity region **130** may extend partially and/or completely through the p-type semiconductor layer **116**. In some embodiments, including embodiments that include a substrate **110**, the reduced conductivity region **130** may extend completely through the active region **114** to/into the n-type semiconductor layer **112**. The reduced conductivity region **130** may be formed using techniques such as those described above with respect to **Figures 1-4**. For example, the reduced conductivity region **130** may be formed by implanting ions into the p-type semiconductor layer **116** through a mask, as described above with reference to **Figure 2A**.

[0066] As further shown in **Figure 5**, the reduced conductivity region **130** may be generally aligned with the bond pad **122**. Since the p-type semiconductor layer **116** may be relatively thin compared, for example, to the substrate **110**, and since current may not spread readily in the p-type semiconductor layer **116**, the presence of the reduced conductivity region **130** may reduce the number of photons generated in the device **100A** directly beneath the wire bond pad **122**. Accordingly, the reduced conductivity region **130** may have a shape that is about the same shape as the wire bond pad **122**. Furthermore, the reduced conductivity region **130** may have an area that is about the same as, slightly less than or slightly greater than, the area of the wire bond pad **122**. In some embodiments, the reduced conductivity region may have a diameter that is about 6 to about 30 μm larger than the diameter of the bond pad **122**. In particular, bond pad **122** may have a diameter of about 100 to 105 μm , and the reduced conductivity region **130** may have a diameter that is about 14 μm larger than the diameter of the bond pad **122**. In embodiments including a substrate (i.e. in which the substrate **110** has not been removed), it may be desirable to provide a reduced conductivity region **130** that is larger in area than the bond pad **122**. For example, if the wire bond pad **122** has a circular shape, the reduced conductivity region **130** may also have a circular shape with an area that is less than, about equal to, or slightly greater than the diameter of the wire bond pad **122**.

[0067] Further embodiments of the invention are shown in **Figures 6A and 6B** in which a light emitting device **100B** is shown including a p-type semiconductor layer **116** an active region **114** and an n-type semiconductor layer **112**. A p-contact metal stack **118** is formed on a surface of the p-type semiconductor layer **116**, and a wire bond pad **122** is formed on a surface of the n-type semiconductor layer **112**.

opposite the p-type semiconductor layer 116. In particular, the light emitting device 100B shown in **Figures 6A and 6B** may not include a substrate.

[0068] As further shown in **Figure 6A**, a reduced conductivity region 130 is provided in the p-type semiconductor layer 116 generally aligned with the wire bond pad 122. The reduced conductivity region 130 may extend from a surface of the p-type semiconductor layer 116 opposite the active region 114 into the p-type semiconductor layer 116. The reduced conductivity region 130 may extend partially and/or completely through the p-type semiconductor layer 116. The reduced conductivity region 130 may have an area that is equal to, greater than, or less than the area of the wire bond pad 122. The reduced conductivity region 130 may be located within the device 100B a distance D2 from the wire bond pad 122. In some embodiments, the distance D2 may be from 0.3 to 10 μm . In particular, the distance D2 may be about 2 to 3 μm .

[0069] **Figures 11A - 11C** are plan view illustrations of a light emitting device 100B including a wire bond pad 122 and an aligned reduced conductivity region 130. As shown therein, the reduced conductivity region 130 may have a peripheral shape that is similar to the peripheral shape of the wire bond pad 122, which in the embodiments illustrated in **Figures 11A-11C** is generally circular. The wire bond pad 122 and the reduced conductivity region 130 may have other peripheral shapes, such as rectangular, star, cross or other shape or combination of shapes.

[0070] As shown in **Figure 11A**, the reduced conductivity region 130 may have an area that is slightly larger than the area of the wire bond pad 122 in some embodiments, while in other embodiments the reduced conductivity region 130 may have an area that is slightly less than (**Figure 11B**) or about equal to (**Figure 11C**) the area of the wire bond pad 122.

[0071] Referring to **Figure 6B**, the reduced conductivity region 130 may extend completely through the p-type semiconductor layer 116 and into the active region 114. In some embodiments, including embodiments that do not include a substrate, the reduced conductivity region 130 may extend completely through the active region 114 to/into the n-type semiconductor layer 112.

[0072] Further embodiments of the invention are shown in **Figure 7A**, which illustrates a light emitting device 100C that includes a p-type semiconductor layer 116, an active region 114 and an n-type semiconductor layer 112. A wire bond pad 122 is formed on a surface of the n-type semiconductor layer 112. A patterned ohmic

contact **118** is formed on a surface of the p-type semiconductor layer **116** opposite the n-type semiconductor layer **112**. The light emitting device **100C** also includes a non-ohmic contact **140** on the p-type semiconductor layer **116** opposite the wire bond pad **122**. In some embodiments, the non-ohmic contact **140** may include, for example, a rectifying Schottky contact. The formation of rectifying Schottky contacts on nitride-based semiconductor materials is well known to those skilled in the art. In other embodiments, the non-ohmic contact **140** may include a non-conductive material, such as silicon dioxide.

[0073] The non-ohmic contact **140** may have a shape that is about the same as the shape of the wire bond pad **122**. The contact **140** may have an area that is slightly less than, about equal to, or slightly greater than the area of the wire bond pad **122**. Accordingly, when a voltage is applied across the terminals of the device **100C**, current may not flow from the non-ohmic contact **140** into the p-type semiconductor layer **116**, which may reduce the number of photons generated in the active layer **114** beneath the wire bond pad **122**.

[0074] Referring to **Figure 7B**, in some embodiments, the metal stack **118** may be formed on the surface of the p-type semiconductor layer **116** in regions other than an area of reduced conductivity **150** opposite the wire bond pad **122**. That is, because the metal stack **118** is not formed in the area **150**, a reduced current may flow through the area **150** when the device is energized, which may reduce the number of photons generated in the active layer **114** beneath the wire bond pad **122**.

[0075] Further embodiments of the invention are illustrated in **Figure 8**. In the embodiments of **Figure 8**, a device **100E** includes a p-type semiconductor layer **116**, an active region **114**, and an n-type semiconductor layer **112**. A p-type contact **118** is formed on a surface of the p-type semiconductor layer **116** opposite the n-type semiconductor layer **112**. A wire bond pad **122** is formed on a surface of the n-type semiconductor layer **112** opposite the p-type semiconductor layer **116**. An ohmic contact **154** is formed on the same surface of the n-type semiconductor layer **112** as the wire bond pad **122**, and is electrically connected to the wire bond pad **122**. The ohmic contact **154** may include a transparent material that forms an ohmic contact to the n-type semiconductor layer **112**, such as ITO.

[0076] A reduced conductivity region **152** is formed in the n-type semiconductor layer **112** beneath the wire bond pad **122**. The reduced conductivity region **152** may extend from the surface of the n-type semiconductor layer **112** at least

partially into the n-type semiconductor layer **112**. In some embodiments, the reduced conductivity region **152** may extend completely through the n-type semiconductor layer **112** and to/into the active region **114**.

[0077] **Figure 9A** illustrates a device **100F** according to further embodiments of the invention. The device **100F** also includes a p-type semiconductor layer **116**, an active region **114**, and an n-type semiconductor layer **112**. A p-type contact **118** is formed on a surface of the p-type semiconductor layer **116** opposite the n-type semiconductor layer **112**. A wire bond pad **122** is formed on a surface of the n-type semiconductor layer **112** opposite the p-type semiconductor layer **116**. An ohmic contact **154** is formed on the same surface of the n-type semiconductor layer **112** as the wire bond pad **122**.

[0078] A first reduced conductivity region **152** is formed in the n-type semiconductor layer **112** beneath the wire bond pad **122**. The first reduced conductivity region **152** may be aligned with the wire bond pad **122** and may extend from the surface of the n-type semiconductor layer **112** at least partially into the n-type semiconductor layer **112**. In some embodiments, the first reduced conductivity region **152** may extend completely through the n-type semiconductor layer **112** and to/into/through the active region **114**.

[0079] A second reduced conductivity region **150** is formed in the p-type semiconductor layer **116**. The second reduced conductivity region **150** may be aligned with the first reduced conductivity region **152** and/or the wire bond pad **122**. The second reduced conductivity region **150** may extend from the surface of the p-type semiconductor layer **116** at least partially into the p-type semiconductor layer **116**, and in some cases to/into/through the active region **114**.

[0080] In embodiments including a reduced conductivity region **150**, **152** on both sides of the device, such as the first reduced conductivity region **152** and the second reduced conductivity region **150** of the device **100F**, the reduced conductivity regions **150**, **152** need not be formed using the same techniques, but could, for example, be formed using different techniques. For example, the first reduced conductivity region **152** could be formed via ion implantation, while the second reduced conductivity region **150** could be formed using plasma treatment and or exposure to hydrogen gas, or vice-versa. Furthermore, one or both of the reduced conductivity regions **150**, **152** could be formed by forming a non-ohmic material on the surface of the respective semiconductor layer **116**, **112** prior to forming an

electrical contact thereon, or by not forming the ohmic contact on an area of the surface of the semiconductor layer that corresponds to the bond pad 122.

[0081] **Figure 9B** illustrates a device **100G** according to further embodiments of the invention. The device **100G** also includes a p-type semiconductor layer **116**, an active region **114**, and an n-type semiconductor layer **112**. A p-type contact **118** is formed on a surface of the p-type semiconductor layer **116** opposite the n-type semiconductor layer **112**. A wire bond pad **122** is formed on a surface of the n-type semiconductor layer **112** opposite the p-type semiconductor layer **116**. An ohmic contact **154** is formed on the same surface of the n-type semiconductor layer **112** as the wire bond pad **122**.

[0082] A reduced conductivity region **152** is formed in the n-type semiconductor layer **112** beneath the wire bond pad **122**. The reduced conductivity region **152** may be aligned with the wire bond pad **122** and may extend from the surface of the n-type semiconductor layer **112** at least partially into the n-type semiconductor layer **112**. In some embodiments, the reduced conductivity region **152** may extend completely through the n-type semiconductor layer **112** and to/into/through the active region **114**.

[0083] A metal contact **118** is formed on a surface of the p-type semiconductor layer **116** opposite the n-type semiconductor layer **112**. The metal contact **118** forms an ohmic contact to the p-type semiconductor layer **116** in a region other than a reduced conductivity area of the surface of the p-type semiconductor layer **116** that is aligned with the wire bond pad **122**.

[0084] The light emitting device **100G** also includes a non-ohmic contact **140** on the p-type semiconductor layer **116** opposite the wire bond pad **122**. In some embodiments, the non-ohmic contact **140** may include, for example, a rectifying Schottky contact. In other embodiments, the non-ohmic contact **140** may include a non-conductive material, such as silicon dioxide.

[0085] The non-ohmic contact **140** may have a shape that is about the same as the shape of the wire bond pad **122**. The contact **140** may have an area that is slightly less than, about equal to, or slightly greater than the area of the wire bond pad **122**. In other embodiments, the non-ohmic contact **140** may include a gap on which no contact is formed.

[0086] Still further embodiments of the invention are illustrated in **Figure 10**, which illustrates a semiconductor light emitting device **100H** that includes a reduced

conductivity region 160 that extends beneath the wire bond pad 122 from a surface of the n-type semiconductor layer 112 and through the device 100G to the opposite surface of the p-type semiconductor layer 116.

[0087] Some chip structures in which embodiments of the invention may be employed are shown in isometric view in **Figures 12 and 13**. For example, **Figure 12** illustrates a chip structure 100J including a carrier substrate 210, such as a silicon substrate, on which an LED structure has been bonded via a metal bonding layer 220. A reflective layer 230 is between the bonding layer 220 and the LED structure that includes a p-type semiconductor layer 116, an active layer 114 and an n-type semiconductor layer 112.

[0088] A pair of bond pads 122 are on the surface of the n-type semiconductor layer 112 opposite the substrate 210. The bond pads 122 are electrically connected to a current spreading structure that includes a plurality of current spreading fingers 154 on the n-type semiconductor layer 112.

[0089] The reduced conductivity region 30 may be formed underneath the bond pads 122, underneath the current spreading fingers 154, and/or under both the bond pads 122 and the current spreading fingers 154.

[0090] An exemplary horizontal chip structure 100K is illustrated in **Figure 13**. The chip structure 100K includes a transparent substrate 110 on which an n-type semiconductor layer 112 is formed. A mesa structure including an active region 114 and a p-type semiconductor layer 116 is on the n-type semiconductor layer. A transparent ohmic contact 118, which may include ITO, is on the p-type semiconductor layer 116. A bond pad 122A is on the transparent ohmic contact layer 118, and a current spreading finger 154A extends from the bond pad 122A. A bond pad 122B is on the n-type semiconductor layer 112, and a current spreading finger 154B extends from the bond pad 122B. A reflective layer 23 (**Figure 1**) may be provided beneath the bond pad 122A and/or the current spreading finger 154A.

[0091] The reduced conductivity region 30 may be formed underneath the bond pad 122A, underneath the current spreading fingers 154A, and/or under both the bond pad 122A and the current spreading finger 154A.

[0092] While embodiments of the present invention are illustrated in **Figures 1-13** with reference to particular light emitting device structures, other structures may be provided according to some embodiments of the present invention. Thus, embodiments of the present invention may be provided by any light emitting structure

that includes one or more of the various current blocking mechanisms as described above. For example, current blocking mechanisms according to some embodiments of the present invention may be provided in conjunction with the exemplary light emitting device structures discussed in the United States Patents and/or Applications incorporated by reference above.

[0093] Embodiments of the present invention have been described with reference to a wire bond pad **22**, **122**. As used herein, the term bond pad includes a light absorbing contact structure. A bond pad may be a single or multiple layers, may be a metal and/or metal alloy and/or may be of uniform or non-uniform composition.

[0094] Furthermore, while embodiments of the present invention have been described with reference to a particular sequence of operations, variations from the described sequence may be provided while still benefiting from the teachings of the present invention. Thus, two or more steps may be combined into a single step or steps performed out of the sequence described herein. For example, a reduced conductivity region may be formed in a semiconductor layer before or after forming a metal layer on the semiconductor layer. Thus, embodiments of the present invention should not be construed as limited to the particular sequence of operations described herein unless stated otherwise herein.

[0095] It will be understood by those having skill in the art that various embodiments of the invention have been described individually in connection with **Figures 1-13**. However, combinations and subcombinations of the embodiments of **Figures 1-13** may be provided according to various embodiments of the present invention. As noted above, the reduced conductivity regions **30** may be used to reduce/prevent carrier recombination in areas of a device where generated light may be likely to be absorbed by some feature of the device, such as a bond pad, a current spreading finger, a passivation region, etc. Thus, in some embodiments, the reduced conductivity regions **30** may be aligned with light-absorbing features and/or regions of a device. However, in some cases, it may be desirable to form reduced conductivity regions **30** in other areas that are not aligned with light absorbing regions or features of a device. For example, it may be desirable to provide reduced conductivity regions **30** in a device that cause the device to generate light having a desired far-field emission pattern. Thus, in some embodiments, reduced conductivity regions **30** may be used to shape the light emission pattern of a light emitting device.

[0096] In the drawings and specification, there have been disclosed embodiments of the invention and, although specific terms are employed, they are used in a generic and descriptive sense only and not for purposes of limitation, the scope of the invention being set forth in the following claims.

WHAT IS CLAIMED IS:

1. A light emitting device, comprising:
a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer;
a non-transparent feature on the p-type semiconductor layer or on the n-type semiconductor layer opposite the p-type semiconductor layer; and
a reduced conductivity region in the p-type semiconductor layer and aligned with the non-transparent feature, the reduced conductivity region extending from a surface of the p-type semiconductor layer opposite the n-type semiconductor layer towards the active region.
2. The light emitting device of Claim 1, wherein the non-transparent region comprises a bond pad, a passivation region, and/or a current spreading finger.
3. The light emitting device of Claim 1, further comprising a substrate including first and second opposing surfaces, wherein the n-type semiconductor is on the first surface of the substrate and wherein the non-transparent feature is on the second surface of the substrate opposite the n-type semiconductor layer.
4. The light emitting device of Claim 1, further comprising a metal stack on the surface of the p-type semiconductor layer.
5. The light emitting device of Claim 4, wherein the metal stack comprises an ohmic layer directly on the p-type semiconductor layer, and a reflective layer on the ohmic layer.
6. The light emitting device of Claim 5, wherein the metal stack comprises a bonding layer on the reflective layer.
7. The light emitting device of Claim 5, further comprising a barrier layer between the reflective layer and the bonding layer.

8. The light emitting device of Claim 1, wherein the reduced conductivity region extends from the surface of the p-type semiconductor layer to the active region.

9. The light emitting device of Claim 1, wherein the reduced conductivity region extends from the surface of the p-type semiconductor layer into the active region.

10. The light emitting device of Claim 1, wherein the reduced conductivity region extends from the surface of the p-type semiconductor layer through the active region.

11. The light emitting device of Claim 1, wherein the reduced conductivity region extends through the p-type semiconductor layer, the active region and into the n-type semiconductor layer.

12. The light emitting device of Claim 11, wherein the non-transparent feature comprises a wire bond pad in contact with the reduced conductivity region, the light emitting device further comprising an ohmic contact on the n-type semiconductor layer adjacent and in electrical contact with the wire bond pad.

13. The light emitting device of Claim 1, wherein the reduced conductivity region extends completely through the n-type semiconductor layer.

14. The light emitting device of Claim 1, wherein the active region comprises a Group III-nitride based active region.

15. The light emitting device of Claim 1, wherein the reduced conductivity region comprises an insulating region.

16. The light emitting device of Claim 1, wherein the reduced conductivity region comprises a region that is not non-transparent.

17. The light emitting device of Claim 1, wherein the reduced conductivity region comprises an implanted region.

18. The light emitting device of Claim 4, wherein the reduced conductivity region corresponds to a region of damage at an interface between the metal stack and the p-type semiconductor layer.

19. The light emitting device of Claim 18, wherein the region of damage comprises a wet or dry etched region of the p-type semiconductor layer.

20. The light emitting device of Claim 18, wherein the region of damage comprises a region of the p-type semiconductor layer exposed to a high energy plasma.

21. The light emitting device of Claim 18, wherein the region of damage comprises a region of the p-type semiconductor layer exposed to H₂.

22. The light emitting device of Claim 18, wherein the region of damage comprises a region of the p-type semiconductor layer exposed to a high energy laser.

23. A light emitting device, comprising:
a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer;
a non-transparent feature on the n-type semiconductor layer opposite the p-type semiconductor layer; and
a metal contact on a surface of the p-type semiconductor layer opposite the n-type semiconductor layer, wherein the metal contact forms an ohmic contact to the p-type semiconductor layer in a region other than a reduced conductivity area of the surface of the p-type semiconductor layer that is aligned with the non-transparent feature.

24. The light emitting device of Claim 23, wherein the non-transparent region comprises a bond pad, a passivation region, and/or a current spreading finger.

25. The light emitting device of Claim 23, further comprising a reduced conductivity region in the p-type semiconductor layer and aligned with the non-

transparent feature and the reduced conductivity area, the reduced conductivity region extending from the surface of the p-type semiconductor layer towards the active region.

26. The light emitting device of Claim 23, further comprising a reduced conductivity region in the n-type semiconductor layer and aligned with the non-transparent feature, the reduced conductivity region extending from a surface of the n-type semiconductor layer opposite the p-type semiconductor layer towards the active region.

27. The light emitting device of Claim 23, further comprising a non-ohmic contact on the surface of the p-type semiconductor layer.

28. The light emitting device of Claim 27, wherein the non-ohmic contact comprises a metal that does not form an ohmic contact with the p-type semiconductor layer.

29. The light emitting device of Claim 27, wherein the non-ohmic contact comprises an insulator on the surface of the p-type semiconductor layer.

30. A light emitting device, comprising:
a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer;
a wire bond pad on the n-type semiconductor layer opposite the p-type semiconductor layer;
a reduced conductivity region in the n-type semiconductor layer and aligned with the wire bond pad, the reduced conductivity region extending from a surface of the n-type semiconductor layer opposite the p-type semiconductor layer towards the active region; and
an ohmic contact on the n-type semiconductor layer adjacent and in electrical contact with the wire bond pad.

31. The light emitting device of Claim 30, further comprising a metal stack on a surface of the p-type semiconductor layer opposite the n-type semiconductor layer.

32. The light emitting device of Claim 31, wherein the metal stack comprises an ohmic layer directly on the p-type semiconductor layer, and a reflective layer on the ohmic layer.

33. The light emitting device of Claim 32, wherein the metal stack comprises a bonding layer on the reflective layer.

34. The light emitting device of Claim 30, wherein the reduced conductivity region comprises a first reduced conductivity region, the light emitting device further comprising a second reduced conductivity region in the p-type semiconductor layer and aligned with the wire bond pad, the second reduced conductivity region extending from a surface of the p-type semiconductor layer opposite the n-type semiconductor layer towards the active region.

35. The light emitting device of Claim 30, further comprising a metal contact on a surface of the p-type semiconductor layer opposite the n-type semiconductor layer, wherein the metal contact forms an ohmic contact to the p-type semiconductor layer in a region other than a reduced conductivity area of the surface of the p-type semiconductor layer that is aligned with the wire bond pad.

36. The light emitting device of Claim 30, further comprising a non-ohmic contact on the reduced conductivity area of the surface of the p-type semiconductor layer.

37. The light emitting device of Claim 36, wherein the non-ohmic contact comprises a metal that does not form an ohmic contact with the p-type semiconductor layer.

38. The light emitting device of Claim 36, wherein the non-ohmic contact comprises an insulator on the surface of the p-type semiconductor layer.

39. The light emitting device of Claim 30, wherein the reduced conductivity region corresponds to a region of damage at an interface between the n-type semiconductor layer and the wire bond pad.

40. The light emitting device of Claim 39, wherein the region of damage comprises a wet or dry etched region of the n-type semiconductor layer.

41. The light emitting device of Claim 39, wherein the region of damage comprises a region of the n-type semiconductor layer exposed to a high energy plasma.

42. The light emitting device of Claim 39, wherein the region of damage comprises a region of the n-type semiconductor layer exposed to H₂.

43. The light emitting device of Claim 39, wherein the region of damage comprises a region of the n-type semiconductor layer exposed to a high energy laser.

44. A method of forming a light emitting device, comprising:
forming a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer;
forming a non-transparent feature on the n-type semiconductor layer opposite the p-type semiconductor layer; and
forming a reduced conductivity region in the p-type semiconductor layer and aligned with the non-transparent feature, the reduced conductivity region extending from a surface of the p-type semiconductor layer opposite the n-type semiconductor layer towards the active region.

45. The method of Claim 44, wherein forming a non-transparent feature on the n-type semiconductor layer comprises forming a wire bond pad, a current spreading finger and/or a passivation region on the n-type semiconductor layer.

46. The method of Claim 44, wherein the reduced conductivity region extends from the surface of the p-type semiconductor layer to the active region.

47. The method of Claim 44, wherein the reduced conductivity region extends from the surface of the p-type semiconductor layer into the active region.

48. The method of Claim 44, wherein the reduced conductivity region extends from the surface of the p-type semiconductor layer through the active region.

49. The method of Claim 44, wherein the reduced conductivity region extends through the active region.

50. The method of Claim 44, wherein the active region comprises a Group III-nitride based active region.

51. The method of Claim 44, wherein forming a reduced conductivity region comprises:

forming a mask layer on the surface of the p-type semiconductor layer, the mask layer having an opening corresponding to the bond pad region; and

implanting atoms into the p-type semiconductor layer through the opening in the mask layer.

52. A method of forming a light emitting device, comprising:

forming a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer;

forming a wire bond pad on the n-type semiconductor layer opposite the p-type semiconductor layer; and

forming a metal contact on a surface of the p-type semiconductor layer opposite the n-type semiconductor layer, wherein the metal contact forms an ohmic contact to the p-type semiconductor layer in a region other than a reduced conductivity area of the surface of the p-type semiconductor layer that is aligned with the wire bond pad.

53. The method of Claim 52, further comprising forming a reduced conductivity region in the p-type semiconductor layer and aligned with the wire bond pad and the reduced conductivity area, the reduced conductivity region extending from the surface of the p-type semiconductor layer towards the active region.

54. The method of Claim 52, further comprising forming a reduced conductivity region in the n-type semiconductor layer and aligned with the wire bond pad, the reduced conductivity region extending from a surface of the n-type semiconductor layer opposite the p-type semiconductor layer towards the active region.

55. The method of Claim 52, further comprising forming a non-ohmic contact on the surface of the p-type semiconductor layer.

56. The method of Claim 55, wherein the non-ohmic contact comprises a metal that does not form an ohmic contact with the p-type semiconductor layer.

57. The method of Claim 55, wherein the non-ohmic contact comprises an insulator on the surface of the p-type semiconductor layer.

58. A light emitting device, comprising:
a p-type semiconductor layer, an n-type semiconductor layer, and an active region between the n-type semiconductor layer and the p-type semiconductor layer;
a bond pad on the p-type semiconductor layer opposite the n-type semiconductor layer; and
a reduced conductivity region in the p-type semiconductor layer and aligned with the bond pad, the reduced conductivity region extending from a surface of the p-type semiconductor layer opposite the n-type semiconductor layer towards the active region.

59. The light emitting device of Claim 58, further comprising a reflector between the bondpad and the p-type semiconductor layer.

60. The light emitting device of Claim 58, further comprising a current spreading finger on the p-type semiconductor layer, wherein the reduced conductivity region is further aligned with the current spreading finger.
