ABSTRACT OF THE DISCLOSURE

Provided are improved coatings, polymeric dispersions, and polymeric composites, which include PNP$s$. Also provided are methods for forming improved coatings, polymeric dispersions, and polymeric composites, which include PNP$s$. The PNP$s$ have polymerized units of at least one multi-ethylenically-unsaturated monomer have a mean diameter of from 1 to 50 nanometers. PNP$s$ having polymerized units of at least one multi-ethylenically-unsaturated monomer and at least one surface-active monomer are also provided.
AUSTRALIA
PATENTS ACT 1990
COMPLETE SPECIFICATION

NAME OF APPLICANT(S):
Rohm and Haas Company

ADDRESS FOR SERVICE:
DAVIES COLLISON CAVE
Patent Attorneys
1 Little Collins Street, Melbourne, 3000.

INVENTION TITLE:
Improved coating and coating composition

The following statement is a full description of this invention, including the best method of performing it known to me/us:-
This invention relates to an improved coating and an improved fluid coating composition. In particular, this invention relates to a dry coating including crosslinked polymeric nanoparticles (hereinafter "PNPs"), the dry coating having at least one of the following properties improved relative to that of a dry coating absent the PNPs: block resistance, print resistance, mar resistance, scrub resistance, burnish resistance, dirt pickup resistance, adhesion, gloss, flexibility, toughness, impact resistance, drying time, coalescent demand, water resistance, chemical resistance, biological fouling resistance, and stain resistance. This invention also relates to a fluid coating composition including PNPs, the fluid coating having at least one of the following properties improved relative to that of a fluid coating absent the PNPs: paint open time, rheology, and stability. This invention also relates to PNPs having surface active groups. This invention also relates to polymeric composites and polymeric dispersions containing PNPs. This invention also relates to methods for providing the improved coatings, fluid coating compositions, polymeric dispersions, and polymeric composites containing PNPs.

"Coatings" herein include compositions applied to various substrates and commonly identified as architectural coatings such as, for example, flat coatings, semigloss coatings, gloss coatings, primers, topcoats, stain-blocking coatings, penetrating sealers for porous substrates such as chalky surfaces, concrete, and marble, elastomeric coatings, mastics, caulks, and sealants; industrial coatings such as, for example, board and paneling coatings, transportation coatings, furniture coatings, and coil coatings; maintenance coatings such as, for example, bridge and tank coatings and road marking paints; leather coatings and treatments; floor care coatings; paper coatings; personal care coatings such as for hair, skin, nails, woven and nonwoven fabric coatings and pigment printing pastes; and adhesive coatings such as, for example, pressure sensitive adhesives and wet- and dry-laminating adhesives. Coatings having improvement in at least one property such as, for example, block resistance, print resistance, mar resistance, scrub resistance, burnish resistance, dirt pickup resistance, adhesion,
gloss, flexibility, toughness, impact resistance, drying time, coalescent demand, water resistance, chemical resistance, and stain resistance have long been sought. "Coating compositions" and "fluid coating compositions" herein refer to compositions which when dried or allowed to dry, with or without the application of heat, after having been applied to a substrate form a coating. Coating compositions having improvement in at least one property such as, for example, desired rheology and thickener efficiency have also been sought.

WO 200075244 discloses binding agents formed by reacting one or more epoxide-functional binding agents with carboxyl functional metal-organic nanoparticles having a mean particle size of 5 to 200 nanometers.

It is desired to provide coatings and coating compositions with at least one improved property as described herein. It has now been found that such improvements are provided in coating compositions and in coatings formed from coating compositions which include PNPs having a mean diameter of 1 to 50 nanometers, the PNPs comprising as polymerized units at least one multi-ethylenically-unsaturated monomer.

In a first aspect of the present invention there is provided an improved coating, including a coating composition, and PNPs having a mean diameter of 2 to 8 nanometers, said PNPs comprising as polymerized units at least one multi-ethylenically-unsaturated monomer, wherein the PNPs comprise as polymerized units at least 10 weight percent of units derived from at least one multi-ethylenically-unsaturated monomer; and at least one copolymerized unit derived from at least one of the following monomers: aldehyde-reactive group-containing monomers; drying-promoting monomers selected from ethylenically-unsaturated monomers containing at least one basic amine group; surface-active monomers selected from fluoromonomers, silicon containing monomers, and poly(alkylene-oxide) containing monomers; and acid-containing monomers selected from acrylic acid and methacrylic acid monomers.

In a second aspect of the present invention there is provided a method for providing an improved coating, including the steps of:
forming PNP s having a mean diameter of 2 to 8 nanometers, said PNP s
comprising as polymerized units at least one multi-ethylenically-unsaturated monomer;
forming a coating composition comprising said PNP s; and
grafting at least one poly(alkylene-oxide) molecule to the dried coating,
wherein the PNP s comprise:
(a) at least one copolymerized unit derived from at least one of the following
monomers:
aldehyde-reactive group-containing monomers;
drying-promoting monomers selected from ethylenically-unsaturated monomers
containing at least one basic amine group;
surface-active monomers selected from fluoromonomers, silicon containing
monomers, and poly(alkylene-oxide) containing monomers; and
at least one copolymerized unit derived from at least one acid monomer
acid-containing monomers selected from acrylic acid and methacrylic acid monomers;
(b) at least one copolymerized unit derived from at least one surface-active
monomer selected from fluoromonomers, silicon containing monomers, and
poly(alkylene-oxide) containing monomers; and
(c) at least one copolymerized unit derived from at least one acid monomer.

In a third aspect of the present invention there is provided a method for forming
a polymeric dispersion, including the steps of: forming PNP s having a mean diameter
of 2 to 8 nanometers, said PNP s comprising as polymerized units at least one
multi-ethylenically-unsaturated monomer; providing a reaction mixture comprising
said PNP s and at least one ethylenically-unsaturated monomer; and subjecting said
reaction mixture to at least one bulk, solution, gas-phase, emulsion, mini-emulsion, or
suspension polymerization condition.

In a fourth aspect of the present invention there is provided PNP s, including
polymerized units of at least one multi-ethylenically-unsaturated monomer and at least
one surface-active monomer selected from fluoromonomers, silicon-containing
monomers and poly(alkylene-oxide) containing monomers, said PNP having a mean
diameter of from 2 to 8 nanometers.
In a fifth aspect of the present invention, there is provided a polymeric composite, including: PNP's having a mean diameter of 2 to 8 nanometers, said PNP's comprising as polymerized units at least one multi-ethylenically-unsaturated monomer; and polymers comprising as polymerized units at least one ethylenically-unsaturated monomer.

Throughout this specification and the claims which follow, unless the context requires otherwise, the word "comprise", and variations such as "comprises" and "comprising", will be understood to imply the inclusion of a stated integer or step or group of integers or steps but not the exclusion of any other integer or step or group of integers or steps.

The reference in this specification to any prior publication (or information derived from it), or to any matter which is known, is not, and should not be taken as an acknowledgment or admission or any form of suggestion that that prior publication (or information derived from it) or known matter forms part of the common general knowledge in the field of endeavour to which this specification relates.
As used herein, the term "dispersion" refers to a physical state of matter comprising at least two distinct phases wherein one phase is distributed in the second phase, the second phase being continuous.

As used herein, the term "molecular weight", when describing the PNPs, refers to the apparent molecular weight one obtains using standard gel permeation chromatography methods, e.g., using THF solvent at 40°C, 3 Pgel Columns (Polymer Labs), 100 Ångstrom, 10^-3, 10^-4 Ångstroms, 30 cm long, 7.8 mm ID, 1 ml/min, 100 microliter injection volume, calibrated to narrow polystyrene standards using Polymer Labs CALIBRE™ software.

As used herein, the term “Tg” refers to the glass transition temperature as is determined using differential scanning calorimetry (“DSC”) methods.

As used herein, the following abbreviations shall have the following meanings, unless the context clearly indicates otherwise: C = centigrade; um = micron; UV = ultraviolet; rpm = revolutions per minute; nm = nanometer; J = joules; cc = cubic centimeter; g = gram; wt% = weight percent; L = liter; mL = milliliter; MA n = methyl iso-amyl ketone; MIBK = methyl iso-butyl ketone; BA = butyl acrylate; AA = acrylic acid; MAA = methacrylic acid; PS = particle size = mean particle diameter; PMA = poly(methyl acrylate); CyHMA = cyclohexylmethacrylate; EG = ethylene glycol; DPG = dipropylene glycol; DEA = diethylene glycol ethyl ether acetate; BzA = benzylacrylate; BzMA = benzyl methacrylate; MAPS = MATS = (trimethoxysilyl)propylmethacrylate; OFFMA = octafluoropentyl methacrylate; ropyl methacrylate; PETTA = pentaerythriol
tetra/triacetate: PPG4000DMA = polypropyleneglycol 4000 dimethacrylate;
DPEPA = dipentaerythriol pentaacrylate; TMSMA = trimethylsilyl methacrylate;
MOPTSOMS = methacryloyxypropylis(trimethyl)siloxy)methylsilane;
MOPMDMOS = 3'-methacryloyxypropylmethyldimethoxysilane; TAT = triallyl-
1,3,5-triazine-2,4,6-(1H,3H,5H)-trione; IBOMA = isobornyl methacrylate;
PGMEA = propyleneglycol monomethylether acetate; PEGMEMA475 =
poly(ethylene glycol methyl ether)methacrylate Mw=475; EUG= eugenol (4-allyl-
2-methoxyphenol); and PGDMA = propyleneglycol dimethacrylate.

The term “methacrylic” includes both acrylic and methacrylic and the
term “(meth)acrylate” includes both acrylate and methacrylate. Likewise, the
term “(meth)acrylamide” refers to both acrylamide and methacrylamide. “Alkyl”
includes straight chain, branched and cyclic alkyl groups.

All ranges defined herein are inclusive and combinable.

The present invention is directed to coating compositions, coatings formed
from coating compositions, polymeric dispersions, and polymeric composites
which include PNPs, the PNPs having polymerized units of at least one multi-
ethylenically-unsaturated monomer, said PNPs having a mean diameter of from
1 to 50 nanometers, and methods for forming the same. The present invention is
also directed to PNPs having polymerized units of at least one multi-
ethylenically-unsaturated monomer and at least one surface-active monomer,
said PNPs having a mean diameter of from 2 to 8 nanometers.

While the PNPs used in the various embodiments of the present invention
typically have a mean particle diameter of from 2 nm to 8 nm.

The PNPs are formed by the free radical polymerization of at least one
multi-ethylenically-unsaturated monomer. Typically, unless specified otherwise, the
PNPs contain at least 10% by weight based on the weight of the PNPs, of at least one
polymerized multi-ethylenically-unsaturated monomer. Up to and including 100%
polymerized multi-ethylenically-unsaturated monomer, based on
the weight of the PNP's, can be effectively used in the particles of the present invention. It is preferred that the amount of polymerized multi-ethylenically-unsaturated monomer is from 10% to 80% based on the weight of the PNP's, more preferably from 10% to 60% based on the weight of the PNP's, and most preferably from 10% to 25% based on the weight of the PNP's.

Suitable multi-ethylenically-unsaturated monomers useful in the present invention include di-, tri-, tetra-, or higher multi-functional ethylenically unsaturated monomers such as, for example, trivinylbenzene, divinyltoluene, divinylpyridine, divinylnapthalene and divinylbenzene; and such as ethyleneglycol diacrylate, trimethylolpropane triacrylate, diethyleneglycol divinyl ether, trivinylcyclohexane, allyl methacrylate ("ALMA"), ethyleneglycol dimethacrylate ("EGDMA"), diethyleneglycol dimethacrylate ("DEGDMA"), propyleneglycol dimethacrylate, propyleneglycol diacrylate, trimethylolpropane trimethacrylate ("TMPTMA"), divinyl benzene ("DVB"), 2,2-dimethylpropane-1,3-diacrylate, 1,3-butylene glycol diacrylate, 1,3-butylene glycol dimethacrylate, 1,4-butanediol diacrylate, diethylene glycol diacrylate, diethylene glycol dimethacrylate, 1,6-hexanediol diacrylate, 1,6-hexanediol dimethacrylate, tripropylene glycol diacrylate, triethylene glycol dimethacrylate, tetraethylene glycol diacrylate, polyethylene glycol 200 diacrylate, tetraethylene glycol dimethacrylate, polyethylene glycol dimethacrylate, ethoxylated bisphenol A diacrylate, ethoxylated bisphenol A dimethacrylate, polyethylene glycol 600 dimethacrylate, poly(butandiol) diacrylate, pentaerythritol triacrylate, trimethylolpropane triethoxy triacrylate, glyceryl propoxy triacrylate, pentaerythritol tetraacrylate, pentaerythritol tetramethacrylate, dipentaerythritol monohydroxy pentacrylate, divinyl silane, trivinyl silane, dimethyl divinyl silane, divinyl methyl silane, methyl trivinyl silane, diphenyl divinyl silane, divinyl phenyl silane, trivinyl phenyl silane, divinyl methyl phenyl silane, tetravinyl silane, dimethyl vinyl disiloxane, poly(methyl vinyl siloxane), poly(vinyl hydro siloxane), poly(phenyl vinyl siloxane) and mixtures thereof.

Suitable ethylenically-unsaturated monomers which can be incorporated as copolymerized units in the PNP's include, but are not limited to: (meth)acrylic
acid, (meth)acrylamides, alkyl (meth)acrylates, vinyl acetates, alkenyl (meth)acrylates, aromatic (meth)acrylates, vinyl aromatic monomers, nitrogen-containing compounds and their thio-analogs, phosphorus-containing compounds such as phosphoethyl (meth)acrylate ("PEM"), and substituted ethylene monomers.

Typically, the alkyl (meth)acrylates useful in the present invention are (C₁₋C₂₀) alkyl (meth)acrylates. Suitable alkyl (meth)acrylates include, but are not limited to, "low cut" alkyl (meth)acrylates, "mid cut" alkyl (meth)acrylates and "high cut" alkyl (meth)acrylates.

"Low cut" alkyl (meth)acrylates are typically those where the alkyl group contains from 1 to 6 carbon atoms. Suitable low cut alkyl (meth)acrylates include, but are not limited to: methyl methacrylate ("MMA"), methyl acrylate, ethyl acrylate, propyl methacrylate, butyl methacrylate ("BMA"), butyl acrylate ("BA"), isobutyl methacrylate ("IBMA"), hexyl methacrylate, cyclohexyl methacrylate, cyclohexyl acrylate and mixtures thereof.

"Mid cut" alkyl (meth)acrylates are typically those where the alkyl group contains from 7 to 15 carbon atoms. Suitable mid cut alkyl (meth)acrylates include, but are not limited to: 2-ethylhexyl acrylate ("EHA"), 2-ethylhexyl methacrylate, octyl methacrylate, decyl methacrylate, isodecyl methacrylate ("IDMA", based on branched (C₁₀)alkyl isomer mixture), undecyl methacrylate, dodecyl methacrylate (also known as lauryl methacrylate), tridecyl methacrylate, tetradecyl methacrylate (also known as myristyl methacrylate), pentadecyl methacrylate and mixtures thereof. Useful mixtures include dodecyl-pentadecyl methacrylate ("DPMA"), a mixture of linear and branched isomers of dodecyl, tridecyl, tetradecyl and pentadecyl methacrylates, and lauryl-myristyl methacrylate ("LMA").

"High cut" alkyl (meth)acrylates are typically those where the alkyl group contains from 16 to 24 carbon atoms. Suitable high cut alkyl (meth)acrylates include, but are not limited to: hexadecyl methacrylate, heptadecyl methacrylate, octadecyl methacrylate, nonadecyl methacrylate, cosyl methacrylate, eicosyl methacrylate and mixtures thereof. Useful mixtures of
high cut alkyl (meth)acrylates include, but are not limited to: cetyl-eicosyl
methacrylate ("CEMA"), which is a mixture of hexadecyl, octadecyl, cosyl and
eicosyl methacrylate; and cetyl-stearyl methacrylate ("SMA"), which is a mixture of
hexadecyl and octadecyl methacrylate.

The mid-cut and high-cut alkyl (meth)acrylate monomers described above
are generally prepared by standard esterification procedures using technical
grades of long chain aliphatic alcohols, and these commercially available alcohols
are mixtures of alcohols of varying chain lengths containing between 10 and 15
or 16 and 20 carbon atoms in the alkyl group. Examples of these alcohols are the
various Ziegler catalyzed ALFOL alcohols from Vista Chemical (now Sasol)
company, i.e., ALFOL 1618 and ALFOL 1620, Ziegler catalyzed various NEODOL
alcohols from Shell Chemical Company, i.e. NEODOL 25L, and naturally derived
alcohols such as Proctor & Gamble's TA-1618 and CO-1270. Consequently, for
the purposes of this invention, alkyl (meth)acrylate is intended to include not
only the individual alkyl (meth)acrylate product named, but also to include
mixtures of the alkyl (meth)acrylates with a predominant amount of the
particular alkyl (meth)acrylate named.

The alkyl (meth)acrylate monomers useful in the present invention can be
a single monomer or a mixture having different numbers of carbon atoms in the
alkyl portion. Also, the (meth)acrylamide and alkyl (meth)acrylate monomers
useful in the present invention can optionally be substituted. Suitable optionally
substituted (meth)acrylamide and alkyl (meth)acrylate monomers include, but
are not limited to: hydroxy (C_2-C_6)alkyl (meth)acrylates, dialkylamino(C_2-C_6)
alkyl (meth)acrylates, dialkylamino(C_2-C_6)alkyl (meth)acrylamides.

Useful substituted alkyl (meth)acrylate monomers are those with one or
more hydroxyl groups in the alkyl radical, especially those where the hydroxyl
group is found at the β-position (2-position) in the alkyl radical. Hydroxyalkyl
(meth)acrylate monomers in which the substituted alkyl group is a (C_2-C_6)alkyl,
branched or unbranched, are preferred. Suitable hydroxyalkyl (methacrylate
monomers include, but are not limited to: 2-hydroxyethyl methacrylate
("HEMA"), 2-hydroxyethyl acrylate ("HEA"), 2-hydroxypropyl methacrylate, 1-
methyl-2-hydroxyethyl methacrylate, 2-hydroxypropyl acrylate, 1-methyl-2-
hydroxyethyl acrylate, 2-hydroxybutyl methacrylate, 2-hydroxybutyl acrylate
and mixtures thereof. The preferred hydroxyalkyl (meth)acrylate monomers are
HEMA, 1-methyl-2-hydroxyethyl methacrylate, 2-hydroxypropyl methacrylate
and mixtures thereof. A mixture of the latter two monomers is commonly
referred to as "hydroxypropyl methacrylate" or "HPMA."

Other substituted (meth)acrylate and (meth)acrylamide monomers useful
in the present invention are those with a dialkylamino group or
dialkylaminoalkyl group in the alkyl radical. Examples of such substituted
(meth)acrylates and (meth)acrylamides include, but are not limited to:
dimethylaminoethyl methacrylate, dimethylaminoethyl acrylate, N,N-
dimethylaminoethyl methacrylamide, N,N-dimethylaminopropyl
methacrylamide, N,N-dimethylaminobutyl methacrylamide, N,N-di-
ethylaminoethyl methacrylamide, N,N-diethylaminopropyl methacrylamide,
N,N-diethylaminobutyl methacrylamide, N,N-di-
acrylamide, N-(1,3-diphenyl-1-ethyl-3-oxobutyl) acrylamide, N-(1-methyl-1-
phenyl-3-oxobutyl) methacrylamide, and 2-hydroxyethyl acrylamide, N-
methacrylamide of aminoethyl ethylene urea, N-methacryloxy ethyl morpholine,
N-maleimide of dimethylaminopropylamine and mixtures thereof.

Other substituted (meth)acrylate monomers useful in the present
invention are silicon-containing monomers such as γ-propyl tri(C1-C6)alkoxysilyl
(meth)acrylate, γ-propyl tri(C1-C6)alkylsilyl (meth)acrylate, γ-propyl di(C1-
C6)alkoxy(C1-C6)alkylsilyl (meth)acrylate, γ-propyl di(C1-C6)alkyl(C1-
C6)alkoxysilyl (meth)acrylate, vinyl tri(C1-C6)alkoxysilyl (meth)acrylate, vinyl
di(C1-C6)alkoxy(C1-C6)alkylsilyl (meth)acrylate, vinyl (C1-C6)alkoxydi(C1-
C6)alkylsilyl (meth)acrylate, vinyl tri(C1-C6)alkylsilyl (meth)acrylate, and
mixtures thereof.

The vinylaromatic monomers useful as unsaturated monomers in the
present invention include, but are not limited to: styrene ("STY"), α-
methylstyrene, vinyltoluene, p-methylstyrene, ethylvinylnaphthalene,
vinylxylene, and mixtures thereof. The vinylaromatic
monomers also include their corresponding substituted counterparts, such as halogenated derivatives, i.e., containing one or more halogen groups, such as fluorine, chlorine or bromine; and nitro, cyano, (C<sub>1</sub>-C<sub>6</sub>)alkoxy, halo(C<sub>1</sub>-C<sub>6</sub>)alkyl, carb(C<sub>1</sub>-C<sub>6</sub>)alkoxy, carboxy, amino, (C<sub>1</sub>-C<sub>6</sub>)alkylamino derivatives and the like.

The nitrogen-containing compounds and their thio-analogs useful as unsaturated monomers in the present invention include, but are not limited to: vinylpyridines such as 2-vinylpyridine or 4-vinylpyridine; lower alkyl (C<sub>1</sub>-C<sub>6</sub>) substituted N-vinyl pyridines such as 2-methyl-5-vinylpyridine, 2-ethyl-5-vinylpyridine, 3-methyl-5-vinylpyridine, 2,3-dimethyl-5-vinylpyridine, and 2-methyl-3-ethyl-5-vinylpyridine; methyl-substituted quinolines and isoquinolines; N-vinylcaprolactam; N-vinylbutyrolactam; N-vinylpyrrolidone; vinyl imidazole; N-vinyl carbazole; N-vinyl succinimide; (meth)acrylonitrile; 3, 4, or 5 amino styrene; maleimide; N-vinyl-oxazolidone; N,N-dimethyl aminoethyl-vinyl ether; ethyl-2-cyano acrylate; vinyl acetonitrile; N-vinylphthalimide; N-vinyl pyrrolidones such as N-vinyl thiopyrrolidone, 3 methyl-1-vinyl pyrrolidone, 4-methyl-1-vinyl pyrrolidone, 5-methyl-1-vinyl pyrrolidone, 3-ethyl-1-vinyl pyrrolidone, 3-buty1-1-vinyl pyrrolidone, 3,3-dimethyl-1-vinyl pyrrolidone, 4,5-dimethyl-1-vinyl pyrrolidone, 5,5-dimethyl-1-vinyl pyrrolidone, 3,3,5-trimethyl-1 vinyl pyrrolidone, 4-ethyl-1-vinyl pyrrolidone, 5-methyl-5-ethyl-1-vinyl pyrrolidone and 3,4,5-trimethyl-1-vinyl pyrrolidone; vinyl pyrroles; vinyl anilines; vinyl versatates; and vinyl piperidines.

The substituted ethylene monomers useful as unsaturated monomers in the present invention include, but are not limited to: allylic monomers, vinyl acetate, vinyl formamide, vinyl chloride, vinyl fluoride, vinyl bromide, vinylidene chloride, vinylidene fluoride and vinylidene bromide.

The PNP's used in the present invention can be prepared by emulsion polymerization, mini-emulsion, micro-emulsion, suspension polymerization, non-aqueous dispersion polymerization, or solution polymerization. By "solution polymerization" herein is meant free radical addition polymerization in an aqueous or nonaqueous medium which is a solvent for the polymer. By "solvent for the polymer" herein is meant that the polymer absent crosslinking would be
soluble in the polymerization medium, as can be predicted based on the solubility of a polymer made under the same conditions absent the crosslinking monomer for polymers containing less than about 20 wt.% multi-ethylenically unsaturated monomer or by selection of a polymerization medium based on solubility maps as disclosed herein.

The PNP{s} can be prepared in a non-aqueous solvent. Examples of such solvents include, but are not limited to: hydrocarbons, such as alkanes, fluorinated hydrocarbons, and aromatic hydrocarbons, ethers, ketones, esters, alcohols and mixtures thereof. Particularly suitable solvents include dodecane, mesitylene, xylene, diphenyl ether, gamma-butyrolactone, ethyl acetate, ethyl lactate, propyleneglycol monomethyl ether acetate, caprolactone, 2-heptanone, methylisobutyl ketone, diisobutylketone, propyleneglycol monomethyl ether, and alkyl alcohols, such as decanol, t-butanol, and isopropanol ("IPA").

The PNP{s} can be prepared by first charging a solvent heel or, alternatively, a mixture of solvent and some portion of the monomer(s) to a reaction vessel equipped with a stirrer, a thermometer and a reflux condenser. The monomer charge is typically composed of monomer(s), initiator and chain transfer agent, as appropriate. The solvent or solvent/monomer heel charge is heated with stirring under a nitrogen blanket to a temperature from about 55°C to about 125°C. After the heel charge has reached a temperature sufficient to initiate polymerization, the monomer charge or balance of the monomer charge is added to the reaction vessel over a period of 15 minutes to 4 hours while maintaining the reaction at the desired reaction temperature. After completing the monomer mixture addition, additional initiator in solvent can be charged to the reaction and/or hold periods can be employed.

The PNP{s} can be prepared by emulsion polymerization. The emulsion polymers useful in the present invention are generally prepared by first charging water and some portion of the monomer emulsion to a reaction vessel equipped with a stirrer, a thermometer and a reflux condenser. Typically, the monomer emulsion is composed of monomer, surfactant, initiator and chain transfer agent, as appropriate. The initial charge of monomer emulsion is added to a suitable
reactor vessel that is heated with stirring under a nitrogen blanket to a
temperature of from about 55° C to about 125° C. After the seed charge has
reached a temperature sufficient to initiate polymerization, the monomer
emulsion or balance of the monomer emulsion is charged to the reaction vessel
over a period of 15 minutes to 4 hours while maintaining the reaction at the
desired reaction temperature. After completing the monomer emulsion addition,
additional initiator can be charged to the reaction and/or hold periods can be
employed.

In the alternative, the emulsion polymerization can be carried out in a
batch process. In such a batch process, the emulsion polymers are prepared by
charging water, monomer, surfactant, initiator and chain transfer agent, as
appropriate, to a reaction vessel with stirring under a nitrogen blanket. The
monomer emulsion is heated to a temperature of from about 55° C to about 125°
C to carry out the polymerization. After completing the monomer emulsion
addition, additional initiator in solvent can be charged to the reaction and/or
hold periods can be employed.

Suitable PNPs include, for example: HEMA/DEGDMA, MMA/DEGDMA,
MMA/MAPS/DEGDMA, MMA/MAPS/PETTA, MMA/MAPS/PPG4000DMA,
MMA/MAPS/DPEPA, MAPS/DEGDMA, BA/DEGDMA, MMA/MAPS/TMPTMA,
MMA/MAPS/DVB, STY/MAPS/DVB, BA/MAPS/DVB, BA/TMSMA/DVB,
BA/MOPTSOMS/DVB, BA/MOPDMOS/DVB, BA/MAPS/TAT, ALMA/BA/DVB,
IBOMA/MAPS/DVB, IBOMA/MAPS/DVB, BA/DVB, BA/PGDMA, BA/ALMA,
BA/TMPTMA, BA/DPEPA, EHA/DVB, EHA/ALMA, EHA/TMPTMA,
EHA/DPEPA, STY/DVB, STY/ALMA, EHA/STY/ALMA, MMA/BA/ALMA,
STY/MMA/DVB, MMA/2-butadiene/STY, MMA/Ea/ALMA, BA/ALMA/MATS,
STY/MATS/DVB, MMA/BA/MATS, STY/MMA/MATS/DVB,
MMA/BA/MATS/ALMA, BzA/TMPTMA, BzA/DVB, IDMABzMA and
MMA/ALMA/MATS.

Control of particle size and distribution can be achieved by such methods
as choice of solvent, choice of initiator, total solids level, initiator level, type and
amount of multi-functional monomer, type and amount of chain transfer agent,
and reaction conditions. Particle sizes (mean particle diameter) can be determined using standard dynamic light scattering techniques, wherein the correlation functions can be converted to hydrodynamic sizes using LaPlace inversion methods, such as CONTIN.

Initiators useful in the free radical polymerization of the present invention include, for example, one or more of peroxysterers, dialkyl peroxides, alkyl hydroperoxides, persulfates, azoinitiators, redox initiators and the like. Useful free radical initiators include, but are not limited to benzoyl peroxide, tert-butyl peroctoate, t-amyl peroxypivlate, cumene hydroperoxide, and azo compounds such as azoisobutynitrile and 2, 2'-azobis (2-methylbutanenitrile). It is preferred that the free radical initiator is t-amyl peroxypivlate. The amount of the free radical initiator used is typically from 0.05 to 10% by weight, based on the weight of total monomer.

Chain transfer reagents can optionally be used to prepare the polymers useful in the present invention. Suitable chain transfer agents include, for example: alkyl mercaptans such as dodecyl mercaptan, and aromatic hydrocarbons with activated hydorgens such as toluene.

The PNP's typically have an "apparent weight average molecular weight" in the range of 5,000 to 1,000,000, preferably in the range of 10,000 to 500,000 and more preferably in the range of 15,000 to 100,000. As used herein, "apparent weight average molecular weight" reflects the size of the PNP particles. The GPC elution times of the PNP's thereby provide an indication of an apparent weight average molecular weight measurement, and not necessarily an absolute weight average molecular weight measurement.

The PNP's can also be post-functionalized. Such post-functionalization can be by any technique known in the art. Post-polymerization functionalization of the PNP's can be advantageous, such as in compatibilizing the PNP's with other components in the coating composition.

The PNP's are desirably discrete or unagglomerated and dispersible, miscible or otherwise substantially compatible with in the coating composition in the fluid state and in the dried coating.
The compatibility of the PNP's with the balance of the coating composition is typically determined by matching their solubility parameters, such as the Van Krevelen parameters of delta d, delta p, delta h and delta v. See, for example, Van Krevelen et al., Properties of Polymers, Their Estimation and Correlation with Chemical Structure, Elsevier Scientific Publishing Co., 1976; Olabisi et al., Polymer-Polymer Miscibility, Academic Press, NY, 1979; Coleman et al., Specific Interactions and the Miscibility of Polymer Blends, Technomic, 1991; and A. F. M. Barton, CRC Handbook of Solubility Parameters and Other Cohesion Parameters, 2nd Ed., CRC Press, 1991. Delta d is a measure of dispersive interactions, delta p is a measure of polar interactions, delta h is a measure of hydrogen bonding interactions, and delta v is a measure of both dispersive and polar interactions. Such solubility parameters can either be calculated, such as by the group contribution method, or determined by measuring the cloud point of a polymeric material in a mixed solvent system consisting of a soluble solvent and an insoluble solvent. The solubility parameter at the cloud point is based on the weighted percentage of the solvents. Typically, a number of cloud points are measured for the material and the central area defined by such cloud points is defined as the area (range) of solubility parameters of the material.

In certain embodiments of the present invention, the solubility parameters of the PNP and coating composition medium can be substantially similar. In these embodiments, compatibility between the PNP in/with the coating composition is improved and phase separation and/or aggregation of the PNP in the coating is less likely to occur. It is preferred that the solubility parameters, particularly delta h and delta v, of the PNP and coating composition medium are substantially matched. It will be appreciated by those skilled in the art that other properties of the PNP besides the solubility parameters also affect the compatibility of PNP's in coatings.

The PNP's can be used as a dispersion in the polymerization solvent or they can be isolated by, for example, vacuum evaporation, by precipitation into a non-solvent, and spray drying. When isolated, PNP's can be subsequently redispersed in a medium appropriate for incorporation into a coating composition.
The PNP's can be incorporated into a coating composition by admixing the PNP's or a dispersion of the PNP's with other dissolved or dispersed polymers and/or other coatings adjuvants as are well known to those skilled in the art. The coating composition can include an aqueous or non-aqueous medium. The coating composition can contain conventional coating adjuvants such as, for example, tackifiers, pigments, emulsifiers, crosslinkers, monomers, oligomers, polymers, solvents, coalescing agents, buffers, neutralizers, thickeners or rheology modifiers, humectants, wetting agents, biocides, plasticizers, antifoaming agents, colorants, waxes, and antioxidants.

The solids content of the improved coatings of the present invention can be from about 10% to about 85% by volume. Among aqueous coatings, the viscosity is typically from 0.05 to 2000 Pa.s (50 cps to 2,000,000 cps), as measured using a Brookfield viscometer; the viscosities appropriate for different end uses and application methods vary considerably.

The coating can be applied by conventional application methods such as, for example, brush or paint roller, air-atomized spray, air-assisted spray, airless spray, high volume low pressure spray, air-assisted airless spray, curtain coating, roller coating, reverse roller coating, gravure coating, flexography, inkjet, bubble-jet, and electrostatic spray.

The coating can be applied to a substrate such as, for example, plastic including sheets and films, wood, metal, leather, woven or nonwoven fabric, hair, skin, nails, paper, previously painted surfaces, cementitious substrates, and asphaltic substrates, with or without a prior substrate treatment such as a primer.

The coating on the substrate is typically dried, or allowed to dry, at temperatures from 10°C to 200°C.

Coatings having at least one of the following improved properties: block resistance, print resistance, mar resistance, scrub resistance, burnish resistance, dirt pickup resistance, toughness, water resistance, chemical resistance, and stain resistance, relative to the same composition absent the PNP's, can be provided by ensuring that the PNP's are characteristically hard. Hard PNP's can be provided by providing crosslinking higher than required by the overall
invention (i.e., greater than 5, preferably greater than 10, more preferably greater than 15, and even more preferably greater than 20 weight percent of at least one multi-ethylenically unsaturated monomer used to prepare the PNP's) when the Tg is less than ambient temperatures. Alternatively, hard PNP's can be provided by provided that the PNP Tg is greater than ambient (i.e., greater than 25°C, preferably greater than 50°C, more preferably greater than 100°C) by utilizing monomers that yield high Tg polymers (e.g., methacrylic and vinyl aromatic monomers). Preferably, hard PNP's incorporate a combination of both high crosslinking and monomers that yield high Tg polymers to provide sufficiently high hardness for improving coating properties.

Coatings having improved water resistance relative to the same composition absent the PNP's, can also be provided by ensuring that the PNP's are characteristically hydrophobic. Hydrophobic PNP's can be provided by ensuring that the weight percentage of polymerized units of the PNP's derived from hydrophobic monomers, based on total PNP weight, is at least 20 weight percent, preferably at least 40 weight percent, more preferably at least 50 weight percent, even more preferably at least 70 weight percent, and most preferably at least 80 weight percent. Hydrophobic monomers useful in the present embodiment will typically have a water solubility (or weight average water solubility for hydrophobic monomer mixtures) of less than 10, preferably less than 5, more preferably less than 2, and further preferably less than 1 percent at 25°C. By “water solubility” herein is meant, the solubility in water at 25°C. By “weight-averaged water solubility” herein is meant that when more than one second monomer is selected the water solubility is calculated by adding, for each second monomer, the product of its water solubility and its weight fraction based on the total weight of the second monomers. The solubility of monomers in water is known. For example, data are available in “Polymer Handbook” (Second edition, J. Brandrup, E. H. Immergut, Editors, John Wiley & Sons) and “Merck Index” (Eleventh Edition, Merck & Co., Inc. Rahway, N. J., U.S.A.). Data for typical monomers are shown below:

In one embodiment of the present invention, a coating containing a polymer dissolved in a solvent for the polymer is admixed with PNPs, the PNPs having a glass transition temperature higher than that of the polymer. The coating formed from the coating composition exhibits at least one improved property from block resistance, print resistance, mar resistance, scrub resistance, burnish resistance, dirt pickup resistance, toughness, water resistance, chemical resistance, and stain resistance relative to the same composition absent the PNPs.

In one embodiment of the present invention, a coating containing an alkyd dissolved in a solvent for the alkyd is admixed with PNPs having a glass transition temperature higher than that of the polymer. The coating formed from the coating composition exhibits at least one improved property from drying time, block resistance, print resistance, mar resistance, scrub resistance, burnish resistance, dirt pickup resistance, toughness, water resistance, chemical resistance, and stain resistance relative to the same composition absent the PNPs.

In one embodiment of the present invention, a coating containing a polymer dissolved in a solvent for the polymer is admixed with PNPs having a glass transition temperature lower than that of the polymer. The coating formed from the coating composition exhibits at least one improved property from scrub resistance, toughness, flexibility, water resistance, chemical resistance, and stain resistance relative to the same composition absent the PNPs.
In one embodiment of the present invention, an aqueous coating containing a polymer dispersed in an aqueous medium, such as an emulsion polymer, having a particle size greater than 50 nanometers is admixed with PNP's having a glass transition temperature higher than that of the polymer. The dry coating formed from the coating composition exhibits at least one improved property from block resistance, print resistance, mar resistance, scrub resistance, burnish resistance, dirt pickup resistance, toughness, drying time, water resistance, chemical resistance, and stain resistance relative to the same composition absent the PNP's.

In one embodiment of the present invention, an aqueous coating containing a polymer dispersed in an aqueous medium such as an emulsion polymer having a particle size greater than 50 nanometers is prepared in the presence of PNP's. The polymers dispersed in an aqueous medium can be prepared by various polymerization methods, such as emulsion polymerization, mini-emulsion, micro-emulsion, suspension polymerization, non-aqueous dispersion polymerization, or solution polymerization. The dry coating formed from the coating composition exhibits at least one improved property from block resistance, print resistance, mar resistance, scrub resistance, burnish resistance, dirt pickup resistance, toughness, drying time, water resistance, chemical resistance, and stain resistance relative to the same composition absent the PNP's.

In one embodiment of the present invention, a coating containing a polymer dispersed in an aqueous medium such as an emulsion polymer is admixed with PNP's having a glass transition temperature lower than that of the polymer. The dry coating formed from the coating composition exhibits at least one improved property from scrub resistance, block resistance, dirt pickup resistance, toughness, flexibility, water resistance, chemical resistance, and stain resistance relative to the same composition absent the PNP's.

In one embodiment of the present invention, a coating containing a polymer dispersed in an aqueous medium such as an emulsion polymer is admixed with PNP's, the PNP's being provided as a dispersion in a solvent which
is a coalescent for the emulsion polymer. The dry coating formed from the coating composition exhibits at least one improved property from scrub resistance, toughness, flexibility, coalescent demand, water resistance, chemical resistance, and stain resistance relative to the same composition absent the PNP.

In one embodiment of the present invention, a coating including PNP bearing a functional species, such as for example, an antioxidant or an optical brightener, is provided. For example, the functional species can be provided by a corresponding functional monomer introduced in the preparation of the PNP, by post reaction of a PNP, or by physical attachment such as adsorption, hydrogen bonding, etc. of an appropriate species to a PNP. The PNP's provide a more efficient use of the functional species relative to the coating absent the PNP.

The PNP's can also provide a more efficient use of the functional species relative to the coating wherein the functional species are attached to particles larger than 50 nm.

In one embodiment of the present invention a coating composition containing a polymer dispersed in an aqueous medium, such as an emulsion polymer, is admixed with PNP's having a composition including copolymerized fluoronomomers or silicone-containing monomers. The dry coating formed from the coating composition exhibits improved stain resistance, biological fouling resistance (e.g., mildew, microbial, and algae resistance), and chemical resistance relative to the same composition absent the PNP.

In one embodiment of the present invention a coating composition containing a polymer dispersed in an aqueous medium such as an emulsion polymer is admixed with PNP's having a composition including at least one copolymerized aldehyde-reactive group containing monomer. The dry coating formed from the coating composition exhibits improved adhesion to an alkyd relative to the same composition absent the PNP.

By "aldehyde reactive group-containing monomer" is meant herein a monomer that, in a homogeneous solution containing 20% by weight of the monomer and an equimolar amount of formaldehyde at any pH from 1 to 14, will
exhibit greater than 10% extent of reaction between the monomer and formaldehyde on a molar basis in one day at 25 °C. Included as ethylenically unsaturated aldehyde reactive group-containing monomers are, for example, vinyl acetate, acetoacetoyl (meth)acrylate, acetoacetoxypropylmethyl (meth)acrylate, allyl acetoacetate, acetoacetoxybutyrylmethyl (meth)acrylate, vinyl acetoacetamide, acetoacetoxyethyl (meth)acrylamide, 3-(2-vinylsulfanyl)propionamide, N-(2-methyl-1-vinyl-2-imidazolone, 2-phenyl-1-vinyl-2-imidazolone, 2-(3-Oxazolidinyl)ethyl (meth)acrylate, N-(2-vinylvinyl)-2-methyloxazolizine, 4,4-dimethyl-2-isopropenylxazoline, 3-(4-pyrrolidinyl)propyl (meth)acrylate, 2-(meth)acryloyldimethyl N-propionamide, diethanolamine
monovinyl ether, 4-aniline vinyl thioether, (meth)acryloxyacetamidoethyl ethylethylene urea, ethyleneureidoethyl (meth)acrylate, (meth)acrylamidoethyl ethyleneurea, (meth)acrylamidoethyl ethyleneurea, N-(meth)acrylamidoethyl)-N'-hydroxymethylene ethyleneurea, N-(meth)acrylamidoethyl)-N'-methoxymethylene ethyleneurea, N-formamidoethyl)-N'-vinylethyleneurea, N-vinylethyleneurea, N-vinyl-N'-aminoethyl ethyleneurea, N-ethylenureidoethyl)-4-pentanamide, N-(ethylenetioureidoethyl)-10-undecanamide, butyl ethyleneureidoethyl fumarate, methyl ethyleneureidoethyl fumarate, benzyl N-(ethylenureidoethyl) fumarate, benzyl N-(ethylenureidoethyl) maleate, N-(vinylhydroxyethyl) urea, N-(ethylenureidoethyl)-crotonamide, ureidoethyl vinyl ether, 2-ureidoethyl (meth)acrylate, N2-(1-(2-(3-hydroxy-3-(2-propenyl)propylamino)ethyl)-2-imidazolidinone, hydrogen ethyleneureidoethyl itaconamide, ethyleneureidoethyl hydrogen itaconate, bis-ethyleneureidoethyl itaconate, ethyleneureidoethyl undecylate, ethyleneureidoethyl undecylamide, 2-(3-methyl-2-imidazolidone-2-yl)-Dethyl acrylate, N-acryloxyalkyl oxazolizines, acylamidoalkyl vinyl alkyleneurac, aldehyde-reactive amino group-containing monomers as dimethylaminoethyl
methacrylate, and ethylenically unsaturated monomers containing aziridine functionality. PNP s prepared from the following aldehyde-reactive group-containing monomers are particularly preferred: 2-(2-oxo-1-imidazolidinyl)ethyldimethacrylate, 1-[2-[[2-hydroxy-3-(2-propenyl)oxy]propyl]amino]ethyl]-2-imidazolidinone, 2-methyl-1-[2-(2-oxo-1-imidazolidinyl)ethyl] methacrylamide, 2-butenedioic acid, bis[2-(2-oxo-1-imidazolidinyl)ethyl] ester, carbamic acid, [2-(2-oxo-1-imidazolidinyl)ethyl] 2-propenyl ester, AAEM, and combinations thereof.

In this embodiment, the aldehyde-reactive groups can be introduced into the composition of the PNP s by synthesizing the PNP s with aldehyde-reactive group-containing monomers. For example, the aldehyde-reactive group-containing monomers can be included along with multiethylenically unsaturated monomers and ethylenically unsaturated monomers for preparing PNP s having aldehyde-reactive groups. Concentrations of the aldehyde-reactive group-containing monomers typically range from 1 percent to 99 percent, and more typically range from 5 percent to 90 percent, and even more typically range from 10 percent to 80 percent by weight based on the total weight of monomers.

PNP s prepared with aldehyde-reactive group-containing monomers ('aldehyde-reactive PNP s') are useful for improving the adhesion of the resulting films to substrates. For example, emulsion-based paints can be prepared from latex polymers and formulated with aldehyde-reactive PNP s. The aldehyde-reactive group-containing monomers can be added to a coatings formulation along with aldehyde-reactive PNP s for improving the adhesion of the coatings to substrates. As well, the polymerization of monomer emulsion lattices can be carried out in the presence of aldehyde-reactive PNP s. The concentration of the aldehyde-reactive PNP s in the coating formulation for increasing adhesion strength will typically be in the range of from 0.1 percent to 5 percent by weight, more typically in the range of from 0.2 percent to 4 percent by weight, and even more typically in the range of from 0.5 percent to 3 percent by weight, and most typically in the range of from 1 to 2 percent by weight.

In one embodiment, coatings containing a polymer dispersed in an aqueous medium, such as an anionic emulsion polymer, can be admixed with
PNPs having a composition including at least one copolymerized drying-promoting monomer, and a sufficient amount of a volatile base to ensure that the PNP is in an unionized state. Examples of drying-promoting monomers include ethylenically unsaturated monomers which contain basic amine groups. Examples of such monomers containing basic amine groups are described in US 5,527,823 and US 5,804,627. Especially useful monomers include DMAEMA, DMAPMA, and OXEMA (2-(3-oxazolidinyl)ethyl methacrylate), and combinations thereof. Accordingly, “drying-promoting-PNPs” are useful for improving the drying or setting speed of coatings, especially anionic latex-based coatings.

In this embodiment, the drying-promoting groups can be introduced into the composition of PNPs by synthesizing the PNPs with drying-promoting functional monomers. Various drying-promoting functional monomers can be included along with multi-ethylenically-unsaturated monomers and optional other ethylenically-unsaturated monomers for preparing PNPs having drying-promoting groups. Concentrations of the drying-promoting functional monomers typically range from 1 percent to 99 percent, more typically range from 5 percent to 90 percent, and even more typically range from 10 percent to 80 percent by weight based on the total weight of monomers used to synthesize the PNPs. The concentration of the drying-promoting PNPs in the coating formulation is sufficient to reduce the drying time of the coating, which will typically be an amount between 20 percent and 500 percent, more typically between 50 percent and 250 percent, and even more typically between 75 and 150 percent based on the equivalents of anionic charge in the coating formulation.

In one embodiment of the present invention, a coating containing a polymer dissolved in a solvent is admixed with PNPs including at least one copolymerized surface-active monomers, such as fluoromonomers, silicon-containing monomers, or poly(alkylene oxide)-containing monomers having poly(alkylene oxide) segment molecular weights in the range of 100 to 5,000 g/mol (such as monomers including poly(ethylene oxide) segments), or mixtures thereof. In this embodiment, the weight percent of surface-active monomers used for preparing the PNPs is in the range of from 1 to 90%, preferably from 2
to 75%, more preferably from 5 to 50%, and even more preferably from 10 to 40%. PNP-containing fluorine, silicon, and poly(alkylene oxide) groups can also be prepared by reacting PNP-containing reactive groups with fluorine, silicon, and poly(alkylene oxide) chemical moieties that chemically interact with the reactive groups of the PNP. The dry coating formed from the coating composition exhibits improved resistance to the buildup of marine fouling organisms relative to the same composition absent the PNP. While the Tg of the PNP used in the present embodiment is not limited, in certain applications it is preferred that the Tg is less than 25°C, more preferably less than 0°C, and even more preferably less than −25°C for reducing the ability of marine fouling organisms to adhere to coating surfaces.

In one embodiment of the present invention, non-fouling/foulant releasing coatings are provided that may not require expensive, environmentally-detrimental biocides or silicone-based coatings. These coatings are provided by a coating composition which is admixed with crosslinked PNP having a composition including copolymerized acid-containing monomers, such as (meth)acrylic acid, along with at least one fluoromonomers or silicone-containing monomer, or mixtures thereof, coating a substrate with said coating composition, curing or drying said coating, and attaching a poly(alkylene oxide) molecule to said cured or dried coating. Attachment of poly(alkylene oxide) molecules, especially poly(ethylene oxide) ("PEO") molecules to the resulting coating provides a dramatic reduction in adsorption of biomolecules on these surface-modified substrates. Various methods of attaching PEO to substrates that can be applied in the present embodiment can be found in Ostuni, et al., A Survey of Structure Property Relationships of Surfaces that Resist the Adsorption of Protein, Langmuir, 17, 5605-5620 (2001). The presence of acid in bulk matrix films, however, causes a reduction in film properties resulting from water uptake (i.e., water sensitivity). Accordingly, PNP prepared with both surface active monomers (e.g., F and Si) and acid-containing monomers (e.g., MAA or AA) provide acid sites concentrated on the surface of the coating which are accessible for grafting, but which may not contribute to water sensitivity of the coating. In this embodiment, the weight percent of surface active monomers used for
preparing the PNP is in the range of from 1 to 90%, preferably from 2 to 30%, more preferably from 5 to 25%, and even more preferably from 10 to 25%. In this embodiment, the weight percent of acid-containing monomers used for preparing the PNP is in the range of from 1 to 90%, preferably from 2 to 30%, more preferably from 5 to 25%, and even more preferably from 10 to 25%.

While not being bound to a particular theory, the PNP migrate to the cured or dried coating surface and present acid binding sites to the coating surface, which in turn are subsequently grafted with the poly(alkylene oxide) composition, such as a poly(ethylene oxide) ("PEO") composition to form a "PEO brush" which inhibits the deposition of protein on the coating surface. The resulting non-fouling/foul releasing coatings are durable, and easier to apply than present silicone based coatings and also exhibit improved resistance to the buildup of marine fouling organisms relative to the same composition absent the "PEO brush".

In one embodiment, the binder of non-fouling/foul releasing coatings can be low Tg, crosslinkable polymers to which PNP containing both surface-active groups and acid-binding sites are admixed. While not being bound to a particular theory, the PNP in such coatings may migrate to the air interface and provide graftable sites for subsequent surface treatments (e.g., PEO). In this embodiment, "low Tg" refers to Tg less than 25°C, preferably less than 0°C, more preferably less than −25°C.

In one embodiment of the present invention, PNP are provided which have a mean diameter of 1 to 50 nanometers, preferably from 1 to 40 nm, more preferably from 1 to 30 nm, even more preferably from 1 to 20 nm, even further preferably from 1 to 10 nm, and most preferably from 2 to 8 nm, the PNP having as polymerized units of at least one multi-ethylenically-unsaturated monomer and at least one surface-active monomer to form "surface-active PNP". In an alternate embodiment, the surface active PNP additionally contain polymerized units derived from an acid monomer. In another embodiment, the surface active PNP additionally contain poly(alkylene oxide), preferably PEO. Poly(alkylene oxide) can be incorporated into the PNP as described above. These
PNPs can be useful in preparing a variety of materials and coatings used in the architectural, electronic, and transportation fields. For example, surface-active PNP-s containing poly(alkylene oxide) can be useful for improving resistance to biological deposition in architectural and transportation coatings. Surface active PNP-s may also be useful for preparing porogens as described in U.S. Patent 6,271,273.

In one embodiment of the present invention a paper coating composition containing a polymer dispersed in an aqueous medium such as an emulsion polymer is admixed with functionalized PNP-s. The dry coating formed from the coating composition exhibits improved ink receptivity and/or print permanence including, for example, water resistance, offset resistance, and smear resistance relative to the same composition absent the functionalized PNP-s. The coated paper can be preferably used as a substrate for inkjet printing.

In one embodiment of the present invention, a coating composition containing PNP-s having been infused with a functional agent such as, for example, an agronomically active ingredient, and an antistatic agent, the agent being substantially insoluble in the medium of the coating composition, is provided. The dry coating formed from the coating composition exhibits a controlled release rate of the functional agent to the surface of the coating, the rate influenced in part by the glass transition temperature of the PNP.

In one embodiment of the present invention a composition containing PNP-s having been infused with a functional agent such as, for example, a lubricant or a silicone is provided. The modified PNP-s exhibit deposition on and the functional agent exhibits distribution on a textile material during a wash and dry laundering cycle.

In one embodiment of the present invention a composition containing PNP-s having been infused with a functional agent such as, for example, a lubricant or a silicone is provided. The modified PNP is used in a personal care application such as a shampoo or a lotion.

In one embodiment, there is provided a method for forming a polymeric dispersion. The polymeric dispersions of this embodiment are provided by
forming PNP's, providing a reaction mixture comprising the PNP's and at least one monomer, and subjecting the reaction mixture to at least one bulk, solution, gas-phase, emulsion, mini-emulsion, or suspension polymerization condition. In this embodiment, the PNP's are dissolved or dispersed in a monomer or monomer mixture and used in a subsequent polymerization for preparing polymeric dispersions. Any monomers that can be polymerized can be used, and preferably are ethylenically unsaturated monomers. While the PNP's used in the present invention can be incorporated in any type of polymerization, including emulsion, mini-emulsion, bulk, solution, gas-phase, suspension, and combinations thereof, preferred types of subsequent polymerizations include, suspension polymerizations, mini-emulsion polymerizations, micro-emulsion polymerizations, and emulsion polymerizations to provide polymeric dispersions.

While any amount of PNP's can be used for preparing polymeric dispersions, it is preferred to employ levels of 1 to 90 percent, preferably 1 to 75 percent, more preferably 1 to 50 percent, even more preferably 1 to 30 percent PNP's, and even further preferably 1 to 20 percent by weight PNP's based on monomer weight.

Hydrophilic PNP's are favored for preparing polymeric dispersions which use emulsion polymerization techniques. One example of a hydrophilic PNP is one containing polymerized units of 50 MMA / 20 BA / 10 DEGDMA / 20 PEGMEMA475, wherein the number preceding the monomer designation refers to the weight fraction of the polymerized units. Preferred PNP's are not highly soluble in water in the case of mini-emulsion and dispersion polymerization. The PNP's in the polymeric dispersions can be interacting or non-interacting with the later-formed polymer. Interactions can include, for example, covalent bonding, acid/base interaction, and charge transfer interaction. For use in aqueous-based polymerizations, the PNP's are preferably dispersed in water or a water/solvent mixture. PNP's included in such polymeric dispersions can provide a broader accessible range of composition than could be attained by direct formation of a comparative polymer particle formed by emulsion or suspension polymerization, i.e., compositions too hydrophobic or too hydrophilic for direct polymerization can be introduced by adding PNP's formed by solution polymerization. The particle

-30-
dispersions are incorporated into a coating composition and the coating formed therefrom exhibits at least one improved property. The particle dispersions can also be used to form polymeric composites.

In one embodiment of the present invention, PNP's can be dissolved or dispersed in a monomer or monomer mixture and used in a subsequent polymerization for preparing polymeric composites. The monomers used can be any monomer mixture useful for forming polymeric materials, and are preferably ethylenically unsaturated. Any type of polymerization, including emulsion, mini-emulsion, bulk, solution, gas/phase, suspension, and combinations thereof, are useful for preparing the polymeric composites.

While any amount of PNP's can be used for preparing the polymeric composites, it is preferred to employ levels of 1 to 90 percent, preferably 1 to 75 percent, more preferably 1 to 50 percent, and even more preferably 1 to 30 percent PNP's by weight based on monomer weight. The polymeric composites can also be provided using the method of preparing polymeric dispersions as described in the previous embodiment.

In one embodiment of the present invention, PNP's are used in emulsion polymerization processes for improving the properties (e.g., improved stability) of the resulting emulsion polymer particle dispersion. In this embodiment, improved stability refers to reducing the likelihood that the emulsion polymer particles destabilize and become undispersed, i.e., by flocculation, agglomeration, gel formation, and like processes whereby two or more polymer particles interact.

The PNP's are useful as stabilizers for aqueous-based emulsion polymerizations and aqueous based polymer dispersions. In this embodiment, the PNP's contain acid or other functionalities that are hydrophilic. Preferably, the PNP's are prepared using an acid-containing monomer. It is also preferred that the acid content is sufficiently high to provide an electrostatic charge layer around the PNP's. Acid contents of suitable PNP's useful as stabilizers can be estimated by the acid contents of typical "high acid" polymers which are known to act as stabilizers for emulsion polymerizations, e.g., as described in U.S. Pat. No. 4,845,149.
Typically, PNP s which are useful as stabilizers for aqueous dispersions, such as emulsion polymerizations, contain units derived from 1 to 99 weight percent, preferably from 5 to 95 weight percent, more preferably from 8 to 75 weight percent, even more preferably from 15 to 60 weight percent, and further more preferably from 20 to 40 weight percent of at least one acid-containing monomer or acid-forming agent. While any acid-containing monomer can be used, it is typical that the acid-containing monomer is copolymerizable by free radical polymerization. Among such acid-containing monomers, acrylic acid and methacrylic acid are preferably used. Typically, the PNP s which are useful as stabilizers contain units derived from 1 to 50 weight percent, preferably from 2 to 40 weight percent, more preferably from 3 to 20 weight percent, and even more preferably from 5 to 15 weight percent of at least one multi-ethylenically unsaturated monomer. Preferably, the acid functionalities of the PNP s are neutralized with a suitable neutralizing base, such as hydroxides (e.g., sodium hydroxide, potassium hydroxide), amines, and preferably ammonia. More preferably, such PNP s are prepared in an aqueous-compatible solvent, neutralized with a base, and diluted in water prior to carrying out the emulsion polymerization. Even more preferably, the aqueous-compatible solvent is at least partially removed, and most preferably substantially completely removed, from the PNP dispersion when used to stabilize emulsion polymerizations.

While such PNP stabilizers need only contain acid monomers and multi-ethylenically-unsaturated monomers as provided hereinabove, it should be appreciated that the PNP s can optionally contain up to 85 weight percent of units derived from other ethylenically unsaturated monomers which are not acid-containing and not multi-ethylenically-unsaturated monomers. Similarly, the PNP s useful as stabilizers may also contain optional functional monomers including, but not limited to, such functionalities as hydroxyl, acetoacetate, acrylamides, acrylamide / formaldehyde adducts, ureido, amine, and the like.

The PNP s of the present invention can be used as stabilizers (i.e., dispersants) in emulsion polymerizations according to the methods known for using "high acid" polymeric stabilizers (often referred to as "resin supported emulsion polymerization", see for example US 4,845,149 and US 6,020,061).
Ranges for use of PNPs as dispersants in emulsion polymerization are as follows: 5 to 80, preferably 10 to 60, most preferably 15 to 40 weight percent PNPs based on total weight of the PNPs and the emulsion polymer solids.

Among suitable emulsion polymer compositions, any emulsion polymer, copolymer, multi-stage copolymer, interpolymer, core-shell polymer, and the like can be stabilized using the PNPs of the present invention. While any ethylenically unsaturated monomer may be used, it is preferred that the emulsion polymers which are stabilized are prepared from at least one of (meth)acrylic ester and vinylaromatic monomers.

In carrying out emulsion polymerizations containing the PNP stabilizers of the present invention, all of the typical emulsion polymerization components, conditions, and processes can be used, e.g., any known emulsion polymerization emulsifier (soap) may be present (or even absent), initiators, temperatures, chain transfer agents, reactor types and solids content, and the like. Improvements in coatings prepared with emulsion polymers having PNP stabilizers are expected in the following properties: paint open time, gloss, controlled rheology, stability, water resistance, block resistance, heat seal resistance, and dirt pickup resistance.

In one embodiment of the present invention, blends of emulsion polymer latex particles with PNP stabilizers are envisioned, while emulsion polymer latex particles prepared with PNPs as stabilizers are preferred.

In one embodiment, PNPs containing residual unsaturation are subsequently treated with additional monomer(s) under polymerization conditions to form PNPs including at least one second stage polymer. The second stage polymer can exhibit functional behavior such as adhesion promotion, waterproofing such as is afforded by amphiphilic polymers as are disclosed in US Patent No. 5,330,557. The second stage polymer can also exhibit surface active behavior by incorporating surface active monomers. The composite PNPs are incorporated into a coating composition and the coating formed therefrom exhibits at least one improved property.
In one embodiment, a coating is used as a leather treatment to provide a
tanning process for tanning and retanning leather. A process to tan skins
whereby the skins are drummed in the pH range of 3 to 7 (preferably 3.5 to 4.5)
in a buffered aqueous solution containing PNPs is provided. In this embodiment,
it is preferred that the buffered aqueous solution comprises of sodium acetate
and acetic acid, preferably in a 1:1 ratio. A tanned leather is thus obtained that
is fully functional. At the end of its service life, this leather can be disposed of by
burning, and/or buried and or/land-filled with little or no detriment to the
quality of the environment. In such environmentally-friendly tanning processes,
the PNPs preferably contain less than 1 weight percent halogen atoms, more
preferably less than 0.5 weight percent halogen atoms, even more preferably less
than 0.2 weight percent halogen atoms, and most preferably less than 0.1 weight
percent halogen atoms. It is also readily digested by chemical and enzymatic
means to amino acids for use as fertilizer and/or animal feed.

In one embodiment PNPs dispersed in a solvent can be used as a medium
to prepare a hot-tube oligomer and permit isolation of a 100% solids oligomer /
PNP together. This provides PNPs in a "solvent" of oligomer. The PNPs will be
relatively high in molecular weight but as a dispersed phase may not contribute
much to the overall viscosity. For reaction with a polyisocyanate, for example,
hydroxyl content of the PNPs can be desirably lower than that of the oligomer.
Similarly, other crosslinking chemistries including, for example, epoxy-amine or
carboxylate, uv/eb cure (acrylated oligomer), and others can be based on
oligomer/PNP blends.

In one embodiment, an aqueous coating composition containing an
associative thickener and PNPs and, optionally, an emulsion polymer binder,
pigment, and/or other paint adjuvants, provides greater thickening efficiency
than the same composition absent the PNPs. Various associative thickeners are
known in the art and can be used with PNPs in the present invention. Preferred
associative thickeners include at least one of the following types: a
"hydrophobically-modified polyurethane, a hydrophobically-modified alkali-
soluble emulsion, a hydrophobically modified hydroxy ethyl cellulose, a
hydrophobically modified polyvinylalcohol, and a hydrophobically modified
polyacrylamide, and variations thereof. The weight percentage of the associative thickener and the PNP will preferably be at least 0.02, more preferably at least 0.05, and even more preferably at least 0.1 based on the total weight of the aqueous coating composition. Typically, the ranges of weight ratios of the PNP to the associative thickener will be 1:99:99-1, preferably 5:95:95-5; more preferably 10:90:90-10, even more preferably 20:80:80-20, even further preferably 30:70:70-30, and most preferably 40:60:60-40. Typically, the weight percentage of the associative thickener and the PNP will be at most 20, preferably at most 10, and even more preferably at most 5 weight percent based on total weight of the aqueous coating composition. The viscosity of the aqueous coating composition will be at least 0.2 Poise, preferably at least 0.5 Poise, more preferably at least 1 Poise, and even more preferably at least 2 Poise. Typically, the viscosity of the aqueous coating composition will be at most 50 Poise, preferably at most 20 Poise, and more preferably at most 10 Poise. Without being bound by mechanism, it is believed that the PNP can provide additional sites for bridging by the associative thickener.

The following examples are presented to illustrate further various aspects of the present invention.

EXAMPLE 1. Preparation of PNP.

A 500 mL reactor was fitted with a thermocouple, a temperature controller, a purge gas inlet, a water-cooled reflux condenser with purge gas outlet, a stirrer, and an addition funnel. To the addition funnel was charged 201.60 g of a monomer mixture consisting of 18.00 g methyl methacrylate (100% purity), 2.00 g diethylene glycol dimethacrylate (100% purity), 1.60 g of a 75% solution of t-amyl peroxypivalate in mineral spirits (Luperox 554-M-75), and 180.00 g diisobutyl ketone ("DIBK"). The reactor, containing 180.00 g DIBK was then flushed with nitrogen for 30 minutes before applying heat to bring the contents of the reactor to 75°C. When the contents of the reactor reached 75°C, the monomer mixture in the addition funnel was uniformly charged to the reactor over 90 minutes. Thirty minutes after the end of the monomer mixture addition, the first of two chaser aliquots, spaced thirty minutes apart and consisting of 0.06 g of a 75% solution of t-amyl peroxypivalate in mineral spirits (Luperox 554-
M·75) and 2.00 g DIBK, was added. At the end of the second chaser aliquot, the contents of the reactor were held 2½ hours at 80°C to complete the reaction. The resulting polymer was isolated by precipitation with heptane, collected by filtration and dried under vacuum to yield a white powder. This material was redissolved in propyleneglycol monomethylether acetate. The PNPs thus formed had a particle size distribution of from 0.8 to 5.0 nm with mean of 1.4 nm as determined by dynamic laser light scattering, and an apparent molecular weight of 22,642 g/mol with a number average molecular weight of 14,601 g/mol and Mw/Mn distribution of 1.6 as measured by GPC.

EXAMPLE 2. Preparation of PNPs, a AAEM/ALMA copolymer by a semi-batch emulsion polymerization process.

A monomer emulsion was made from a mixture of 17 g deionized water, 8.85 g of 28 % w/w solids ammonium lauryl sulfate (ALS), 12.4 g acetoneacetoxethyl methacrylate (AAEM), and 1.78 g allyl methacrylate (ALMA). A reaction kettle was then prepared with 600 g deionized water, 15.0 g of 28 % w/w solids ALS, and 0.15 g ammonium persulfate (APS) in 1 mL deionized water. The reaction kettle was heated to 90°C while being purged with nitrogen. One half of the monomer emulsion was added to the reaction kettle with stirring at 200 rpm. After 20 minutes, the remaining monomer emulsion was added. The kettle temperature was kept at 90°C for 30 minutes, cooled to 55°C, and then a solution of 0.02 g t-butyl hydroxy peroxide (t-BHP) in 1 mL of deionized water and a solution of 0.010 g sodium sulfosuccinate formaldehyde (SSF) in 1 mL of deionized water were added respectively. The reaction was then cooled to ambient temperature and the emulsion was filtered through 400 and 100 mesh sieves respectively. The sample was isolated from water by freeze-drying to produce a white friable, free flowing powder. The resulting white powder was washed with copious amounts of doubly distilled and deionized water to remove most of the surfactant.
EXAMPLE 3. Preparation of PNP from AAEM/ALMA copolymer prepared by a
batch emulsion polymerization process.

A monomer emulsion was made from a mixture of 17 g deionized water,
8.85 g of 28% w/w solids ALS, 12.4 g AAEM, and 1.78 g ALMA in a bottle. A
reaction kettle was then prepared with 600 g deionized water, 15.0 g of 28% w/w
solids ALS, and 0.15 g APS in 1 mL deionized water. The reaction kettle was
heated to 90° C while being purged with nitrogen. The monomer emulsion was
added all at once to the reaction kettle with stirring at 200 rpm. After 30
minutes, the temperature of the reaction flask was cooled to 75° C, and then a
solution of 0.02 g t-BHP in 1 mL of deionized water was added. The reaction was
cooled further to 55° C, and a solution of 0.010 g SSF in 2 mL of deionized water
was added. The reaction was cooled to ambient temperature and the emulsion
was filtered through 400 and 100 mesh sieves respectively.

EXAMPLE 4. Preparation of PNP from a gradual-addition
polymerization process.

A monomer emulsion was made from a mixture of 100 g water, 1.60 g of
28% w/w solids ALS, 68 g ethyl acrylate (“EA”), 17 g methyl methacrylate
(“MMA”), 12.5 g divinyl benzene (“DVB”), and 5 g methacrylic acid (“MAA”). A
reaction kettle containing 445 g water, 22.2 g of 28% w/w solids ALS and 0.37 g
APS was heated to 85° C under a nitrogen atmosphere. The monomer emulsion
was fed to the kettle over 90 minutes. The reaction was held at 85° C for 30
minutes after the end of the feed, and then cooled to 65° C. After cooling, 1.33 g
of 10% iron sulfate (FeSO₄) was added. After 1 minute, 0.2 g of 70% t-BHP was
added and after 2 minutes 0.10 g of 100% ascorbic acid (“AA”) and the
reaction held for 15 minutes. A second chaser system was added in the same
sequence and over the same time period. The reaction was then cooled to
ambient temperature and filtered through a 400 mesh sieve.
**EXAMPLE 5. Preparation of various PNP s**

PNP compositions are reported in Table 5.1. These polymers were prepared according to the general procedures of Examples 1-4. The abbreviation "Mw" refers to the weight average molecular weight and the term "Mn" refers to the number average molecular weight. The term "Dist" refers to the ratio of Mw/Mn. The apparent molecular weights were measured using a standard GPC method with tetrahydrofuran as the solvent.

PNPs of composition 80 BA / 10 MMA / 10 DEGDMMA are prepared in MIBK at a solids level of 5%. A 1000g sample of this composition is placed in a 2 liter flask and the MIBK removed under reduced pressure utilizing a rotary evaporator. Solution #1 is prepared in a beaker and heated to 60°C with stirring until Pharmagel is fully dissolved. Solution #2 is stirred at room temperature in a beaker until the Padmac and NaCl are fully dissolved. Then, solution #1 is added to solution #2 with stirring. Then, the monomer mixture is made by placing 333.00 g of methyl methacrylate in a beaker along with 0.018 g of benzoquinone and 3.30 g of lauryl peroxide; this mixture is stirred for 20 minutes at room temperature to allow for complete dissolution of the benzoquinone and lauryl peroxide. The Padmac/Pharmagel mixture is then added to the reactor and stirred for 10 minutes at 245 rpm. The monomer/PNP mixture is then added in order to form a monomer dispersion within the reactor. The reactor temperature is then raised to 65°C over one hour in order to initiate polymerization of the monomer. The temperature is allowed to reach 74°C and then maintained at that temperature by the addition of cold water. Upon completion of the exotherm, the temperature is maintained at 74°C for 15
minutes. Then, 0.6 mL of Triton CF-32 is added to the reactor, and the
temperature is raised to 90°C for two hours. Finally, the reactor is cooled to
room temperature, and the product is collected by filtration.

5 EXAMPLE 7. Preparation of suspension polymer
The process of Example 6 is repeated except that PNPs of composition 54
MMA/36 BA/10 DEGDMA prepared in MIBK at a solids level of 5% are used.

The above mixture is placed in a reactor and homogenized for a period of 30 minutes in order to obtain a stable mini-emulsion. Then, the temperature is raised to 75 °C for two hours in order to polymerize the styrene monomer. Upon cooling to room temperature, the material is filtered and characterized.

EXAMPLE 10. Emulsion polymerization to form Polymer/PNP Composite

PNPs of composition 50 MMA/20 BA/10 DEGDMA/ 20 PEGMEMA475 is prepared in MIBK at a final solids level of 5%. A 1000g sample of these PNP are placed in a 2 liter flask and the MIBK removed under reduced pressure utilizing a rotary evaporator. To this is added 335 g MMA and 600 g BA – the mixture is stirred until it appeared homogenous.

A 3 liter, four-neck, round bottom glass flask is equipped with a mechanical blade stirrer, a thermocouple to monitor temperature, a reflux condenser, a means to heat and cool, and a nitrogen atmosphere. The flask is charged with 400 g DI water and is heated to 85 °C. A monomer pre-emulsion is prepared from 280 g DI water, 11 g sodium dodecylbenzene sulfonate (23% aqueous solution), the monomer / PNP mixture formed above and 15 g AA. The reaction flask is charged with 4 g ammonium persulfate dissolved in 20 g DI water and 16 g (solids basis) of a 100 nm seed latex with a total of 29 g of DI water. The pre-emulsion and 1.5 g ammonium persulfate dissolved in 45 g DI water were added over three hours. Heating and cooling were applied as necessary to maintain the reaction temperature at 83 °C. When the additions are complete, 30 g DI water is used to rinse the pre-emulsion container into the flask. After 30 minutes, the flask is cooled to 60 °C. Once a temperature of 55 °C is reached through cooling, 0.008 g of FeSO₄.7 H₂O dissolved in 5 g DI water is added, followed by 0.40 g of 70% aqueous tert butyl hydroperoxide in 45 g DI
water and 0.25 g of sodium formaldehyde sulfoxylate dissolved in 45 g DI water added drop-wise over one hour. The reaction mixture is cooled to 45 °C and the pH is adjusted with 14 g 14% aqueous ammonia. After cooling to room temperature the emulsion polymer is filtered. The emulsion polymer of this example has a composition of 60 BA/33.5 MMA/5 PNP/1.5 AA.

COMPARATIVE EXAMPLE C. Preparation of emulsion polymer without PNP. The process of Example 3 is repeated without PNP. Coatings containing the polymers of Examples 6/7, 8/9, and 10 including PNP having a mean particle diameter of 1 to 100 nanometers are expected to exhibit at least one of higher strength, lower tack, better block and better film formation relative to coatings of otherwise the same composition containing the polymers of Comparative Examples A, B, and C, respectively.

EXAMPLE 11-A. Leather treatment (tanning) with PNP composition PNP T is a 15% (90 EUG/10TMTPA) in cyclohexanone. It has a measured average particle size of 1.5 nanometers. All percentages are based on the weight of pickled stock.

Pickled stock of 1.2 mm thickness from a local tannery is neutralized using a conventional process. A piece of the pickled stock (100 G.) is put in a 1 gallon glass jar and is floated with 200% of a 5% sodium chloride aqueous solution. The jar is sealed and is its contents tumbled at room temperature in a rotating paint can mixer for 15 minutes to wash the stock. The wash float is decanted and its pH measured to be ~3.5. The flaccid pickled stock in the glass jar is next floated with a fresh offer of 100% of 5% salt solution and to this system is added 2% anhydrous sodium acetate. The jar is sealed and the system is tumbled continuously for 4 hours to neutralize the pelt. After this time the float has a pH of ~4.5 and indicates that it embodies a 1:1 buffer of acetic acid and sodium acetate. The shrink temperature of the neutralized pelt is measured using a standard test method, and is found to be a typical 60 Celsius. To the jar is then added PNP T (50 g), and an additional 50% of the 5% salt solution. The jar is sealed and is manually shaken to quickly homogenize the contents. A
foamy three phase system is observed akin to that tanners get when wet skins are degreased with kerosene. The glass jar and its contents are then tumbled at room temperature for 24 hours in the paint can mixer. After this time, the tumbling is stopped. The pelt is pulled out of the jar. It has a rigid/full bodied handle and its thickness is measured at 1.8 millimeters to signify a filling ability of the tanning treatment. The shrink temperature of the treated pelt is evaluated and is measured at 93 °C. This high shrink temperature signifies that PNP T transforms the pelt to a stable leather and hence demonstrates the tanning ability of PNP T. The leather is then cut into 2 equal parts. One part is split along its plane into 2 sheets of equal 0.9 millimeter thickness using conventional means. No problems of gumming and operational irregularities are experienced. The 3 leathers are air dried. Each has a white/opaque color, is quite flexible, and is fully agreeable aesthetically to signify its good potential to make articles of commerce like shoes and upholstered furniture. The spent two phase tanning liquor above is analyzed as follows to determine the residual content of the PNP tanning agent. It is put in a 250 milliliter separatory funnel and the top cyclohexanone layer is collected. It is washed once with an equal amount of de-ionized water to remove residual acetic acid. It is then dried over anhydrous Magnesium Sulfate. An aliquot of this cyclohexanone solution (20 G.) is taken to dryness in an oven heated to 60 °C. The weight of the residue is 1 g. This residue is analyzed by HPLC and its identity determined to be predominantly natural animal grease/fat. Thus the uptake of PNP T by the pelt is substantially 100%.

EXAMPLE 11-B. 100% Solids polyurethane adhesive
A premix of PNP dispersion, monomer and initiator is prepared as follows:
PNP (85 BA/15 HEA, 10 nm particles, 15% in acetone) 1000 g
Butyl acrylate 255 g
Hydroxyethyl acrylate 45 g
Di (tert-butyl) peroxide 5.7 g
The mixture is submitted to polymerization conditions in a tubular reactor at 250 C and 3500 psi according to the procedure described in EP 1010706. The
product solution in acetone is stripped in a wiped-film evaporator to afford a 100% "solids" dispersion of 10 nm PNP polyol in the oligomer polyol "solvent". The resulting polyol composition is used in place of conventional polyether polyol, polyester polyol or acrylic polyol in 2-part polyisocyanate cure adhesives or coatings. The resulting coating compositions are expected to be lower in viscosity prior to application than comparative systems and provide improved strength after cure due to the reinforcing effect of the PNP.

**EXAMPLE 11-C. Coating Composition exhibiting enhanced thickening effect**

ACRYSOL RM-825 (associative thickener, Rohm and Haas Company) requires 2 wt% to provide a viscosity of 5 Poise to water. A mixture containing 50 wt% RM-825 solids and 50 wt% of PNP's with a mean diameter of 4 nm (40% BA, 40% MMA and 10 trimethylolpropane triacrylate) provides a viscosity of 5 Poise with only 0.2 wt% of the mixture added to water. In addition to high efficiency in aqueous formulations the mixture of this invention is also less sensitive to variations in the aqueous formulation.

**EXAMPLE 12. The PNP's described in the following table were prepared in MEK (15 – 21 percent solid) having surface active monomer (F or Si containing monomers) according to the synthetic methods described according to the general procedures in Examples 1 to 4.**

Polymer films were prepared by combining PARALOID B-82 (a low-acid containing acrylic obtainable from Rohm and Haas Company) with each of these PNPs dispersed in MEK, diluting with MEK or acetone, and casting and drying films on substrates. The distribution of surface active F and Si, as measured by VG-XPS, at the surface of the films, is recorded in the following Table.

</table>

The results in this table indicate that the surface concentration of the active elements, and therefore that of the PNPs, is considerably higher than would be expected if the PNPs were uniformly distributed throughout the matrix of the film.

**EXAMPLE 13:** Testing Films for Resistance to Algae Growth

Films of the MEK diluted films of Example 12 were prepared on microscope slides and suspended in 4 oz jars with 90 ml growth medium (Alga-Gro Freshwater Medium from Carolina Biological Supply Company). The growth
medium was inoculated with 10 ml of unidentified green algal culture obtained from a fish tank. The algae demonstrated a strong ability to stick on untreated glass slides in previous tests. The films were incubated in a rotary shaker @ ~150 RPM and 30°C under light (F20W T12CW). Observations of algal growth, expressed as percent area coverage, were made weekly for three weeks. Growth medium was periodically replaced to provide fresh nutrient for the algae. The slides were subsequently placed in a second tank and vigorously stirred under light for five additional weeks. The percent area coverage of the film by algae was measured for each film and reported in the following table.

The results in this table show that the films with surface active PNP's were more resistant to fouling than the matrix polymer absent the PNP's.

**EXAMPLE 14.** PNP's were prepared in MEK (15 – 21 percent solids) having both surface active monomer (F or Si containing monomers) and acid containing monomers (MAA or AA) as described in the following table.
EXAMPLE 15. The PNP s of Example 14 were blended with non-acid containing acrylic polymer coating formulations to provide coatings having acid sites concentrated on coating surfaces for subsequent PEO grafting, but which are not water sensitive. The PNP s of Example 14 were combined with PARALOID B-82 (Rohm and Haas Company), according to the compositions described in the following table.

Each coating composition (15-A, B, C, and D) was drawn down on two glass slides at 25 mil wet thickness. After air drying several days, one of each slide was subjected to grafting by placing the film-covered slides into a large evaporating dish with a PEO solution.
DI Water 90 g
PEO 3350 10 g 2990 µM
TEA 18.1 mg 179 µM
Diimide 30.6 mg 160 µM

A large excess of PEO and ~11 fold excess of Diimide was used. Reaction was allowed to take place for 1 hour, after which the slides were rinsed in running DI Water for 1 ½ hrs and then another 1 ½ hours in still DI Water. After several hours of air drying they were placed into a RT vacuum oven overnight. The PEO-grafted and ungrafted reference coatings were tested for resistance to algae growth according to the testing procedures in Example 13. The percent area coverage of each film by Algae growth after four weeks was in the range of from 0 to 10 percent.

EXAMPLE 16 to 27. PNP's used in Emulsion Polymerizations

EXAMPLE 16: PNP's of methyl methacrylate/ methacrylic acid /trimethylol propane triacrylate (70/20/10 wt. %) were prepared via solution polymerization as follows: A 5 liter reactor was fitted with a thermocouple, a temperature controller, a purge gas inlet, a water-cooled reflux condenser with purge gas outlet, a stirrer, and a monomer feed line. To a separate vessel was charged 450.00 grams of a monomer mixture (A) consisting of 315.00 gm. methyl methacrylate (MMA), 90.00 gm methacrylic acid (MAA), and 45.00 gm trimethylol propane triacrylate (TMPTA). To an additional vessel was charged an initiator mix (B) consisting of 18.00 gm. of a 75% solution of t-amyl peroxypivalate in mineral spirits (Triganox 125-C75), and 112.50 gm. isopropyl alcohol. A charge of 2325.00 gm isopropyl alcohol was added to the reactor. After sweeping the reactor with nitrogen for approximately 30 minutes, heat was applied to bring the reactor charge to 79°C. When the contents of the reactor reached 79°C, a dual feed of both the monomer mixture (A) and the initiator mix (B) to the reactor. The two mixtures were fed uniformly using feed pumps over 120 minutes. At the end of the monomer and initiator feeds, the batch was held at 79°C for 30 minutes before adding the first of three initiator chasers.
consisting of 9.00 grams of a 75% solution of t-amyl peroxyivalate in mineral spirits (Triaxinol 125-C75), and 22.50 gm. Isopropyl alcohol. A second initiator chaser addition was made 30 minutes after the first initiator chaser addition. Similarly, the final initiator chaser addition was made 30 minutes after the second initiator chaser addition. The batch was then held at the polymerization temperature of 79°C for and additional 2½ hours to achieve full conversion of monomer. At the end of the final hold, the batch was neutralized with a mixture of 42.5 gm of an aqueous 50% solution of NH₂OH and 450.00 gm water. The neutralized polymer solution was transferred to a roto evaporator and stripped of solvent at ~ 35°C under full house vacuum. After removing all solvent the batch was further dilution with water to ~ 40% polymer (PNP) in water. Particle size was measured at ~ 5.0 nm. The resulting aqueous PNP dispersion can be used as a stabilizer for emulsion polymerizations.

**EXAMPLE 17.** 295.3 grams of deionized water was added to a 2-liter, 4 neck round bottom flask equipped with a side arm, condenser, stirrer, and thermocouple. 160.6 grams (51.6% active in water) of ammonia neutralized acrylic acid based PNP's, pH 8 - 9 (70MMA/20MAA/10TMPTA, particle size less than 10 nm – prepared according to Example 16) were then added to the round bottom flask and used as a stabilizer. The flask contents was heated to 85°C under a nitrogen sweep and then 6.8 grams of a monomer mix consisting of 145.9 grams of styrene, 185.7 grams of 2-ethyl hexyl acrylate and 0.35 grams of butyl mercaptoopropionate was added. Immediately after adding the 6.8 grams of monomer mix to the flask an ammonium persulfate solution (0.33 grams of ammonium persulfate dissolved in 3 grams of de-ionized water) was added to the flask and the contents of the flask is held at 85°C for 15 minutes. After the 15 minute hold an additional ammonium persulfate solution (1.0 gram of ammonium persulfate dissolved in 17.8 grams of water) was added to the flask and the remaining monomer mix is fed to the flask over 150 minutes. Sixty minutes into the monomer mix feed an ammonium persulfate cofeed solution (1.2 grams of ammonium persulfate dissolved in 29.9 grams of water) was added to the flask over 120 minutes. 140 minutes into the monomer mix feed the reaction
temperature is increased to 87°C. Upon completion of the monomer mix feed the contents of the flask was held at 87°C for an additional 60 minutes. Afterwards, the contents of the flask was cooled to 25°C and filtered through a 100/325 mesh set of stacked screens, yielding a negligible quantity of coagulated polymer. The resulting filtered emulsion polymerization product had a solids content of 48.1%, pH 8.3, particle size of 700 nm and a viscosity of 1,340 cps.

**EXAMPLE 18 – 27:** The PNPs listed in the following table are prepared according to the method of Example 17 and are used in emulsion polymerizations according to Example 16. Utilizing PNPs of different compositions results in different particle sized latexes and variations on the improved properties they exhibit. The resulting emulsion polymers are used for formulating coatings which have improved open time, gloss, desirable rheology, stability, water resistance, block resistance, heat seal resistance, and/or dirt pickup resistance over comparable emulsion polymerizations prepared without these PNPs.

Throughout this specification and the claims which follow, unless the context requires otherwise, the word "comprise", and variations such as "comprises" and "comprising", will be understood to imply the inclusion of a stated integer or step or group of integers or steps but not the exclusion of any other integer or step or group of integers or steps.

The reference to any prior art in this specification is not, and should not be taken as, an acknowledgement or any form of suggestion that that prior art forms part of the common general knowledge in Australia.
THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:

1. An improved coating, comprising: a coating composition, and crosslinked polymeric nanoparticles ("PNPs") having a mean diameter of 2 to 8 nanometers, said PNP's comprising as polymerized units at least one multi-ethylenically-unsaturated monomer; wherein the PNP's comprise as polymerized units at least 10 weight percent of units derived from at least one multi-ethylenically-unsaturated monomer; and at least one copolymerized unit derived from at least one of the following monomers: aldehyde-reactive group-containing monomers; drying-promoting monomers selected from ethylenically-unsaturated monomers containing at least one basic amine group; surface-active monomers selected from fluoromonomers, silicon containing monomers, and poly(alkylene-oxide) containing monomers; and acid-containing monomers selected from acrylic acid and methacrylic acid monomers.

2. The improved coating of Claim 1, wherein the coating is in the fluid state.

3. A method for providing an improved coating, comprising the steps of: forming crosslinked polymeric nanoparticles ("PNPs") having a mean diameter of 2 to 8 nanometers, said PNP's comprising as polymerized units at least one multi-ethylenically-unsaturated monomer; forming a coating composition comprising said PNP's; and grafting at least one poly(alkylene-oxide) molecule to the dried coating, wherein the PNP's comprise: (a) at least one copolymerized unit derived from at least one of the following monomers: aldehyde-reactive group-containing monomers; drying-promoting monomers selected from ethylenically-unsaturated monomers containing at least one basic amine group; surface-active monomers selected from fluoromonomers, silicon containing monomers, and poly(alkylene-oxide) containing monomers; and
at least one copolymerized unit derived from at least one acid monomer acid-containing monomers selected from acrylic acid and methacrylic acid monomers; 
(b) at least one copolymerized unit derived from at least one surface-active monomer selected from fluoromonomers, silicon containing monomers, and poly(alkylene-oxide) containing monomers; and 
(c) at least one copolymerized unit derived from at least one acid monomer.

4. The method for providing an improved coating according to Claim 3, further comprising the steps of:

applying said coating composition to a substrate; and

drying said coating composition.

5. A method for forming a polymeric dispersion, comprising the steps of:

forming crosslinked polymeric nanoparticles ("PNPs") having a mean diameter of 2 to 8 nanometers, said PNPs comprising as polymerized units at least one multi-ethylenically-unsaturated monomer;

providing a reaction mixture comprising said PNPs and at least one ethylenically-unsaturated monomer; and

subjecting said reaction mixture to at least one bulk, solution, gas-phase, emulsion, mini-emulsion, micro-emulsion, or suspension polymerization condition.

6. The method for forming a polymeric dispersion according to Claim 5, wherein the PNPs are dispersed in an aqueous phase prior to subjecting the admixture to polymerization conditions.

7. Crosslinked polymeric nanoparticles ("PNPs") comprising polymerized units of at least one multi-ethylenically-unsaturated monomer and at least one surface-active monomer selected from fluoromonomers, silicon-containing monomers and poly(alkylene-oxide) containing monomers, said PNPs having a mean diameter of from 2 to 8 nanometers.
8. A polymeric composite, comprising:
   crosslinked polymeric nanoparticles ("PNPs") having a mean diameter of
   2 to 8 nanometers, said PNPs comprising as polymerized units at least one multi-
   ethylenically-unsaturated monomer; and
   polymers comprising as polymerized units at least one ethylenically-
   unsaturated monomer.

9. A method for providing an improved coating, comprising the steps of:
   forming crosslinked polymeric nanoparticles ("PNPs") having a mean
diameter of 2 to 8 nanometers, said PNPs comprising as polymerized units at least one
multi-ethylenically-unsaturated monomer; and
   forming a coating composition comprising said PNPs.

10. An improved coating, comprising: a coating composition, and crosslinked
polymeric nanoparticles ("PNPs") having a mean diameter of 2 to 8 nanometers, said
PNPs comprising as polymerized units at least one multi-ethylenically-unsaturated
monomer; wherein the PNPs comprise as polymerized units at least one copolymerized
unit derived from acid-containing monomers selected from acrylic acid and
methacrylic acid monomers.

11. A coating according to Claim 1, substantially as hereinbefore described and/or
exemplified.

12. A method for providing a coating according to Claim 3, substantially as
hereinbefore described and/or exemplified.

13. A method for forming a polymeric dispersion according to Claim 5,
substantially as hereinbefore described and/or exemplified.
14. Crosslinked polymeric nanoparticles according to Claim 7, substantially as hereinbefore described and/or exemplified.

15. A polymeric composite according to Claim 8, substantially as hereinbefore described and/or exemplified.

17. A polymeric dispersion prepared by the method of any one of Claims 5, 6 and 13.
