ABSTRACT

The present invention discloses methods of reducing injury resulting from cardiovascular disease, such as myocardial infarction, and/or promoting myocardial repair. The methods include administering an ephrin and pharmaceutical compositions including ephrins to a subject. Kits useful for accomplishing the same are also provided.

CROSS-REFERENCE TO RELATED APPLICATION

[0001] This application is a divisional of U.S. patent application Ser. No. 13/299,096, filed Nov. 17, 2011, now allowed, and claims the benefit of U.S. Provisional Application No. 61/414,741, filed Nov. 17, 2010. The disclosure of each application is incorporated by reference herein in its entirety.

STATEMENT REGARDING ELECTRONIC FILING OF A SEQUENCE LISTING

[0002] A Sequence Listing in ASCII text format, submitted under 37 C.F.R. §1.821, entitled 5218-198TSDV_ST25.txt, 6,874 bytes in size. generated on Nov. 6, 2013 and filed via EFS-Web, is provided in lieu of a paper copy. This Sequence Listing is hereby incorporated by reference into the specification for its disclosures.

FIELD OF THE INVENTION

[0003] The present invention concerns methods of reducing injury resulting from cardiovascular disease or events, such as myocardial infarction, and/or promoting myocardial repair. The present invention further concerns pharmaceutical compositions and kits useful for accomplishing the same.

BACKGROUND OF THE INVENTION

[0004] The heart generally lacks an endogenous regenerative capacity sufficient for repair after injury. Consequential left ventricular (LV) remodeling after myocardial infarction (MI) leads to LV dilatation, ultimately leading to heart failure (Pfeiffer & Braunwald, 1991; Gaudron et al., 1993; Goldstein et al., 1998; Holmes et al., 2005). To reduce this epidemiologic and fiscal burden, it is imperative that strategies be developed to preserve cardiomyocyte survival, subsequently reducing myocardial infarct size, and reducing overall LV remodeling.

[0005] Immediately after coronary occlusion, ischemic myocytes downstream from the occlusion become necrotic and/or undergo apoptosis (Cheng et al., 1996; MacLellan & Schneider, 1997; Fuchu et al., 1998) or autophagy (Nakai et al., 2007; Dorn & Diwan, 2008; Porrello & Delbridge, 2009). Cardiac troponin I is released, which can be measured in plasma and correlates to the size of injury (Bodor et al., 1995; Chapelle, 1999; Braunwald et al., 2002; Nageh et al., 2003; Oyama & Sisson, 2004; Laffe, 2005). Neutrophils infiltrate the tissue immediately, while leukocytes, predominantly macrophages, arrive shortly thereafter and participate in digestion of necrotic cellular debris. Neutrophils in the ischemic tissue can be toxic to the surrounding myocytes, because they release reactive oxygen species and proteolytic enzymes which further injure the surviving myocytes (Lefer & Granger, 2000; Frangogiannis et al., 2002; Frangogiannis, 2008; Lambert et al., 2008; Nah & Rielle, 2009). Once damage occurs, a hypoxic cellular scar forms that leads to contractile dysfunction and heart failure (Fishbein et al., 1978; Frangogiannis et al., 2002; Virag & Murty, 2003; Dorn, 2006).

[0006] Since the discovery of the Eph (erythropoietin-producing hepatocellular carcinoma) receptor tyrosine kinase (RTK) in 1987 (Hirai et al., 1987), a great deal of effort has been focused on elucidating Eph receptor tyrosine kinase (RTK) and ephrin ligand signaling in the context of numerous pathologies. A distinguishing characteristic of Eph-ephrin interactions is the ability to generate bidirectional signaling. “Forward” signaling occurs in the direction of the receptor-expressing cell, while “reverse” signaling occurs in the direction of the ligand expressing cell (Bruckner et al., 1997; Mellitzer et al., 1999; Klein, 2001; Kulander & Klein, 2002). Upon ligand binding and receptor activation, endocytic internalization of the complex occurs (Pasqualetto, 2010), leading to downregulation of the protein. Intracellular cascades downstream of Eph/ephrin signaling are involved in cellular survival, growth, differentiation, and motility (Zhou, 1998; Kulander & Klein, 2002; Arvanitis & Davy, 2008; Pasqualetto, 2008, 2010). The EphA1 receptor has been linked to angiogenesis through endothelial cell migration. Like the ephrinA1 ligand, EphA1 is induced by TNF-α, VEGF, and IL-β, leading to cellular adhesion via integrins and vessel destabilization (Pandey et al., 1995; Cheng et al., 2002a; Cheng et al., 2002b; Moon et al., 2007). Similarly, the EphA2 receptor, expressed on endothelial cells, is widely reported as a key player in angiogenesis, particularly in development and cancer (Ogawa et al., 2000; Drantley-Sieders et al., 2004; Drantley-Sieders et al., 2006; Wykosky et al., 2008).

[0007] Of the at least five ephrinA ligands, ephrinA1 is unique in that it is currently the only ligand that binds all eight EphA receptors known to be expressed in mice. Aside from its predominant characterization as a pro-angiogenic factor in adult mouse tumors, (Easty et al., 1999; Ogawa et al., 2000; Iida et al., 2005), ephrinA1 appears to be involved in inflammation and apoptosis. It was reported in 2006 that Eph receptors are differentially expressed at early and late stages of inflammation (Ivanov & Romanovsky, 2006). For example, at earlier stages of inflammation, EphA2 and EphrinB2 expression is predominantly localized to epithelial and endothelial cells, promoting disruption of the endothelial/epithelial barrier. However, as the inflammatory process progresses, expression of EphA1, EphA3, EphB3, and EphB4 on these cells decreases, allowing infiltrating leukocytes to adhere to endothelial cells by disrupting endothelial epithelial barriers (Ivanov & Romanovsky, 2006). EphrinA1/EphA receptor expression changes also appear to be involved in regulating pathways involved with apoptosis. In 2006, Munoz and colleagues reported that EphA4 deficient mice exhibited both defective T cell development and increased numbers of apoptotic cells (Munoz et al., 2006).

SUMMARY OF THE INVENTION

[0008] Embodiments of the present invention provide methods of reducing injury following cardiovascular events or disease in a subject in need thereof, comprising administering to the subject a therapeutically effective amount of an ephrin. Further embodiments of the present invention provide administering the ephrin at the time of onset of the cardiovascular event or disease, after awareness of the cardiovascular event or disease and/or before the onset of the cardiovascular event or disease.

[0009] Embodiments of the present invention provide methods of reducing injury following myocardial infarction in a subject in need thereof, comprising administering to the subject a therapeutically effective amount of an ephrin. Further embodiments of the present invention provide administering the ephrin at the time of myocardial infarction, after myocardial infarction and/or before myocardial infarction.
[0010] Embodiments of the present invention also provide methods of promoting myocardial repair following myocardial injury in a subject in need thereof, comprising administering to the subject a therapeutically effective amount of an ephrin. According to particular embodiments, the ephrin can be administered at the time of myocardial infarction, after myocardial infarction and/or before myocardial infarction.

[0011] Embodiments of the present invention further provide methods of reducing myocardial injury and/or promoting myocardial repair in perfused or nonperfused myocardial tissue.

[0012] Further embodiments of the present invention provide a pharmaceutical composition comprising an ephrin and a pharmaceutically acceptable carrier. In some embodiments, the pharmaceutical composition further comprises an agent useful for treating cardiovascular events or disease. In some embodiments, the agent is useful for treating myocardial infarction.

[0013] A still further embodiment of the present invention provides a kit comprising a composition comprising an ephrin in a pharmaceutically acceptable carrier and a container suitable for delivery of the composition into a parenteral delivery system. In some embodiments, the parenteral delivery system is an intramyocardial administration device.

[0014] The foregoing and other embodiments of the present invention are explained in greater detail throughout.

BRIEF DESCRIPTION OF THE DRAWINGS

[0015] FIG. 1. EphrinA1-Fc distribution in the infarcted myocardium. Anti-human IgG-Fc staining to detect exogenous ephrinA1-Fc in the myocardium 30 min after injection. This representative image shows an abundant concentration of ephrinA1-Fc on the epicardial surface, as well as transmural expression of the protein. To a lesser extent, ephrinA1-Fc was also detected 4 hours post-injection, but could not be detected 24 hours or 4 days post-injection. Scale bar, 200 µm.

[0016] FIG. 2. EphrinA1-Fc administration reduces infarct size, chamber dilation, necrosis, and thinning of the left ventricular free wall. Representative histological images shown are of vehicle-treated (A) and ephrinA1-Fc-treated (B) hearts four days post-MI. There was a 50% reduction in infarct size (C), 64% less necrosis (D), 35% less chamber dilation (E), and 32% less thinning of the left ventricular free wall (F). n=7 control, n=9 IgG-Fc, n=9 ephrinA1-Fc, P<0.05; † different from control, * different from IgG-Fc.

[0017] FIG. 3. Intramyocardial ephrinA1-Fc administration reduces tissue injury. Administration of ephrinA1-Fc resulted in a 54% reduction in cTnI serum levels 4 days after MI (A), (n=8 control, n=13 vehicle, n=11 ephrinA1-Fc). Cleaved PARP expression was reduced with ephrinA1-Fc administration (B). BAG-1 protein (C) increased with ephrinA1-Fc administration by 36% when normalized to GAPDH, P<0.05; † different from control, * different from MI.

[0018] FIG. 4. EphrinA1-Fc reduces inflammatory cell infiltration. EphrinA1-Fc administration significantly reduced infiltration of neutrophils (A) and leukocytes (B) at 4 days. n=3 control, n=9 IgG-Fc, n=9 ephrinA1-Fc, P<0.05; † different from control, * different from MI. Representative images of Ly6G+ neutrophil infiltration (top panels) and CD45+ pan-leukocyte infiltration (bottom panels) are shown in control (left), vehicle-treated (middle) and ephrinA1-Fc-treated (right) hearts. Scale bar in A (Control) represents 50 µm.

[0019] FIG. 5. Altered gene expression of ephrinA1 and EphA receptors in response to MI and MI+ ephrinA1-Fc. Following MI, ephrinA1 gene expression was significantly reduced (grey bars), and remained relatively unchanged in response to ephrinA1-Fc administration (black bars). Receptors A1, A2, A3 and A7 were significantly upregulated in response to MI, by 5-fold, 2-fold, 5-fold and 28%, respectively, while EphA6 remained unchanged. EphA6 was detected in control hearts but dropped significantly following MI, and expression was not recovered with ephrinA1-Fc administration. In response to ephrinA1-Fc administration, receptors A1 and A2 were further upregulated, by approximately 2-fold each, and A4 was also upregulated by at least 2-fold. Values were calculated using the Ct method, normalized to GAPDH, and presented here as fold changes relative to uninjured control (white bars), n=8 control, n=8 MI, n=8 ephrinA1-Fc, P<0.05; † different from control, * different from MI.

[0020] FIG. 6. EphrinA1 protein distribution in the myocardium. Representative immunostaining for ephrinA1 protein showed a low basal expression of ephrinA1 in cardiomyocytes of control hearts (A and D), intense staining in endo- and epicardial myocardocytes following 4 days non reperfused MI (B and E), and more intense staining in myocardocytes as well as numerous granulation tissue cells in the infarct zone following ephrinA1-Fc treatment at 4 days post-MI (C and F). EphrinA1 total protein expression (G) was reduced by 50% in response to MI, but only reduced 36% in response to ephrinA1-Fc administration (normalized to GAPDH). Scale bars: 100 µm in A, 20 µm in D.

[0021] FIG. 7. EphrinA1-Fc increases pAKT/AKT. (A), representative blot of phosphorylated and total AKT, with the average densitometric analysis of three repeated blots. n=5 control, n=3 MI, n=3 ephrinA1-Fc, P<0.05; † different from control, * different from MI. (B), representative blot of NF-κB p65 protein expression, normalized to GAPDH. n=3 control, n=3 MI, n=3 ephrinA1-Fc.

DETAILED DESCRIPTION

[0022] The foregoing and other aspects of the present invention will now be described in more detail with respect to other embodiments described herein. It should be appreciated that the invention can be embodied in different forms and should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art.

[0023] Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention pertains. The terminology used in the description of the invention herein is for the purpose of describing particular embodiments only and is not intended to be limiting of the invention. As used in the description of the invention and the claims set forth herein, the singular forms “a,” “an,” and “the” are intended to include the plural forms as well, unless the context clearly indicates otherwise.

[0024] All publications, patent applications, patents and other references cited herein are incorporated by reference in their entireties for the teachings relevant to the statement and/or paragraph in which the reference is presented.

[0025] As used herein, the phrase “reducing injury” refers to any type of action or treatment that imparts an effect to decrease, minimize or even maintain the level of injury.
Accordingly, reducing injury indicates that the subject’s condition is not worsened and may be improved with respect to the injury of concern as compared with the level of injury in the absence of treatment or action described herein to reduce injury.

0026 As used herein, “cardiovascular disease” or “heart disease” is a term used to describe a range of diseases or events that affect the heart and/or vasculature. Types of heart disease include, but are not limited to, coronary heart disease, cardiomyopathy, ischemic heart disease, heart failure, inflammatory heart disease, valvular heart disease and aneurysm. Heart disease can be assessed using clinical parameters and/or assessments known to those skilled in the art of diagnosing and/or treating the same, for example, physical examinations, detection of signs and symptoms of cardiovascular disease, electrocardiogram, echocardiogram, chest X-ray, blood tests to detect cardiac biomarkers, etc. Biomarkers typically used in the clinical setting, but are not limited to, cardiac troponins (C, 1, and I), CK and CK-MB, and myoglobin.

0027 As used herein, “myocardial infarction” or “MI” refers to a rapid development of myocardial necrosis, which may be caused by the interruption of blood supply to the heart resulting in a critical imbalance between oxygen supply and demand of the myocardium. This may result from plaque rupture with thrombus formation in a coronary vessel leading to an acute reduction of blood supply to a portion of the myocardium; that is, an occlusion or blockage of a coronary artery following the rupture of a susceptible atherosclerotic plaque. If untreated for a sufficient period of time, the resulting ischemia or restriction in blood supply and oxygen shortage can cause damage or death, i.e., infarction of the heart. In general, this damage is largely irreversible, and clinical therapies thus far mainly aim at delaying the progression of heart failure to prolong survival. Myocardial infarction can be assessed using clinical parameters and/or assessments known to those skilled in the art of diagnosing and/or treating the same, for example, physical examinations, detection of signs and symptoms of myocardial infarction, electrocardiogram, echocardiogram, chest X-ray, blood tests to detect cardiac biomarkers including troponins, CK, and CK-MB, etc.

0028 As used herein, “reperfusion” refers to the restoration of blood flow or supply to the myocardium or myocardial tissue that has become ischemic or hypoxic. Modalities for reperfusion include, but are not limited to, chemical dissolution of the occluding thrombus, i.e., thrombolysis, administration of vasodilators, angioplasty, percutaneous coronary intervention (PCI), catheterization and coronary artery bypass graft (CABG) surgery.

0029 As used herein, “ephrin” or “ephrins” (erythropoietin-producing hepatocellular (Eph)/Eph receptor interacting protein refers to a family of membrane-attached proteins that are ligands of class V (EPH-related) receptor protein-tyrosine kinases. Ephrins are divided into the ephrin-A (EFNA) class, which are anchored to the membrane by a glycosylphosphatidylinositol linkage, and the ephrin-B (EFNB) class, which are transmembrane proteins. Ephrin-A (EFNA) class includes ephrin A1, ephrin A2, ephrin A3, ephrin A4 and ephrin A5, as well as variants and isoforms thereof. Ephrin-B (EFNB) class includes ephrin B1, ephrin B2 and ephrin B3, as well as variants and isoforms thereof.

0030 According to embodiments of the present invention, ephrins employed in the methods described herein include the full length polypeptide, polypeptide fragments of the full length polypeptide, variants and isoforms of the ephrin, fusion proteins and/or chimeric proteins comprising, consisting essentially of, and/or consisting of an ephrin or a polypeptide fragment of an ephrin joined to an exogenous polypeptide sequence, and immunogenic fragments of the ephrin. Non-limiting examples of polypeptide sequences of ephrin A1, and/or isoforms thereof, include human (Accession Nos. P20827.2, AAH132698.1, NP_004419.2 and NP_872626.1), mouse (Accession Nos. P52793.1, NP_034237.3 and NP_001155897.1), wild boar (Accession No. NP_001116582.1), cattle (Accession No. NP_001029464.1), zebrabfish (Accession No. NP_000577.2), dog (XP_547553.1 and XP_852071.1), xenopus laevis (Accession Nos. NP_001088798.1 and NP_001081390.1), rat (Accession No. NP_446051.2), chimpanzee (Accession Nos. XP_001149802.2 and XP_00308473.1) and Xenopus tropicalis (Accession No. NP_001101206.1) sequences, as well as sequences of synthetic constructs (Accession Nos. ABM81648.1, AAC42510.1 and AAX29949.1).

0031 The ephrin may be mammalian, non-mammalian, recombinant, purified, non-purified or a crude extract comprising an ephrin. In some embodiments, the ephrin belongs to the ephrin-A class of ephrins. In further embodiments, the ephrin is ephrin A1, ephrin A2, ephrin A3, ephrin A4, ephrin A5, or a combination thereof. In still other embodiments, the ephrin is ephrin A1.

0032 In some embodiments, the polypeptide sequence for isoform 1 of ephrin A1 from mouse is:

In further embodiments, the present invention may comprise, consist essentially of and/or consist of nucleic acids that encode the polypeptides and/or fragments that comprise the ephrins as set forth herein. These nucleic acids can be part of a recombinant nucleic acid construct comprising any combination of restriction sites and/or functional elements as are well known in the art that facilitate molecular cloning and other recombinant DNA manipulations. Thus, the present invention further provides a recombinant nucleic acid construct that comprises a nucleic acid encoding a polypeptide and/or biologically active fragment employed in this invention.

In further embodiments, the ephrin may comprise, consist essentially of, and/or consist a fragment of the full length polypeptide as set forth in any of SEQ ID NO:1-4. In an embodiment, this fragment may comprise, consist essentially of, and/or consist of the extracellular domain of the ephrin. In a particular embodiment, the fragment may be amino acids 1-182 of SEQ ID NO:1. In another particular embodiment, the fragment may be amino acids 1-182 of SEQ ID NO:3. In yet another particular embodiment, the fragment may be amino acids 22-131 of SEQ ID NO:3.

In particular embodiments, the ephrin comprises, consists essentially of and/or consists of a fusion and/or chimeric protein that comprises, consists essentially of and/or comprises a polypeptide fragment of an ephrin fused to an exogenous peptide sequence. In particular embodiments, the exogenous peptide sequence of the fusion and/or chimeric protein is the Fc region of human IgG, where there are at least four IgG subtypes—lgG1, lgG2, lgG3, and lgG4, in particular lgG1. In further embodiments, the ephrin is mouse ephrin A1-Fc. Mouse ephrin A1-Fc is a chimeric protein that comprises the extracellular domain of mouse ephrin A1 fused by means of a polypeptide linker to the Fc region of human IgG, In still further embodiments, the ephrin is human ephrin A1-Fc. Human ephrin A1-Fc is a chimeric protein that comprises the extracellular domain of human ephrin A1 fused to the Fc region of human IgG, In still further embodiments, the ephrin may be a disulfide-linked homodimer.

The present invention further includes the use of homologs, as well as methods of obtaining homologs, of the polypeptides and/or fragments employed in this invention. As used herein, an amino acid sequence or protein is defined as a homolog of a polypeptide or fragment of the present invention if it shares significant homology or identity to one of the polypeptides and/or fragments of the present invention. Significant homology means at least 60%, 65%, 75%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99% and/or 100% homology with another amino acid sequence. Significant identity means at least 60%, 65%, 75%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99% and/or 100% homology with another amino acid sequence.

As used herein, the term "protein" or "polypeptide" is used to describe a chain of amino acids that correspond to those encoded by a nucleic acid. A polypeptide or protein of this invention can be a peptide, which usually describes a chain of amino acids of from two to about 30 amino acids. The term polypeptide as used herein also describes a chain of amino acids having more than 30 amino acids and can be a fragment or domain of a protein or a full length protein. Furthermore, as used herein, the term polypeptide can refer to a linear chain of amino acids or it can refer to a chain of amino acids that has been processed and folded into a functional protein. It is understood, however, that 30 is an arbitrary number with regard to distinguishing peptides and polypeptides and the terms can be used interchangeably for a chain of amino acids. The polypeptides of the present invention can be obtained by isolation and purification of the polypeptides from cells where they are produced naturally, by enzymatic (e.g., proteolytic) cleavage, and/or recombinantly by expression of nucleic acid encoding the polypeptides or fragments of this invention. The polypeptides and/or fragments
employed in this invention can also be obtained by chemical synthesis or other known protocols for producing polypeptides and fragments.

[0042] The term "fragment," as applied to a polypeptide, will be understood to mean an amino acid sequence of reduced length relative to a reference or full length polypeptide or amino acid sequence and comprising, consisting essentially of and/or consisting of an amino acid sequence of contiguous amino acids identical or almost identical (e.g., 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99% and/or 100% identical) to the reference or full length polypeptide or amino acid sequence. Such a polypeptide fragment according to the invention may be, where appropriate, included in a larger polypeptide of which it is a constituent. In some embodiments, such fragments can comprise, consist essentially of, and/or consist of peptides having a length of at least about 4, 6, 8, 10, 12, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 100, 110, 125, 150, 175, 182, 200, or more consecutive amino acids, including without limitation any lengths within these ranges not explicitly recited herein of consecutive amino acids up to the full length of a polypeptide or amino acid sequence according to the invention.

[0043] The amino acid sequences of this invention are presented in the amino to carboxy direction, from left to right. Any nucleotide sequences are presented in the 5' to 3' direction, from left to right. Nucleic acids can be either single or double stranded (i.e., including the complementary nucleic acid). A nucleic acid can be the complement (e.g., complementary to the full length or only to a portion) of a nucleic acid described.

[0044] The present invention further includes isolated polypeptides, peptides, proteins, fragments, domains and/or nucleic acid molecules that encode polypeptides and fragments thereof that are substantially equivalent to those described for the embodiments of this invention. As used herein, "isolated" polypeptide means a polypeptide that is separated or substantially free from at least some of the other components of the naturally occurring organism or virus, for example, the cell or viral structural components or other polypeptides or nucleic acids commonly found associated with the polypeptide. In particular embodiments, the "isolated" polypeptide is at least about 1%, 3%, 5%, 10%, 25%, 50%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 97%, 98%, 99% or more pure (w/w). In other embodiments, an "isolated" polypeptide indicates that at least about a 5-fold, 10-fold, 25-fold, 100-fold, 1000-fold, or more enrichment of the protein (w/w) is achieved as compared with the starting material.

[0045] As used herein, "substantially equivalent" can refer both to nucleic acid and amino acid sequences, for example a mutant sequence, that varies from a reference sequence by one or more substitutions, deletions, or additions, and the net effect of which does not result in an undesirable adverse functional dissimilarity between reference and subject sequences. In some embodiments, this invention can include substantially equivalent sequences that have an adverse functional dissimilarity. For purposes of the present invention, sequences having equivalent biological activity and equivalent expression characteristics are considered substantially equivalent. Moreover, "substantially equivalent" can refer to the biological activity of polypeptide fragments, domains, portions, etc. having about 50%, 60%, 75%, 85%, 90%, 95%, 97%, 98%, 99%, or more, of the biological activity of the native polypeptide (and can even have a higher level of activity than the native polypeptide).

[0046] As used herein, "therapeutically effective amount" refers to an amount of an agent, i.e., cefdinir, or composition that is sufficient to produce the desired therapeutic effect. The therapeutically effective amount will vary with the age and physical condition of the subject, the severity of the disorder, the duration of the treatment, the nature of any concurrent treatment, the pharmaceutically acceptable carrier used, and like factors within the knowledge and expertise of those skilled in the art. An appropriate "therapeutically effective amount" in any individual case can be determined by one of ordinary skill in the art by reference to the pertinent texts and literature and/or by using routine experimentation. (See, for example, Remington, The Science and Practice of Pharmacy 20th Edition, Lippincott Williams & White, Baltimore, Md. (2000).)

[0047] The therapeutically effective amount, the use of which is in the scope of present invention, will vary somewhat from subject to subject, and will depend upon factors such as the age and condition of the subject and the route of delivery. Such dosages can be determined in accordance with routine pharmacological procedures known to those skilled in the art. For example, an elixir of the present invention can be administered to the subject in an amount ranging from a lower limit of about 0.01, 0.02, 0.03, 0.04, 0.05, 0.06, 0.07, 0.08, 0.09, or 0.1 mg to an upper limit of about 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, or 10.0 mg in a single dose; in an amount ranging from a lower limit of about 0.01, 0.02, 0.03, 0.04, 0.05, 0.06, 0.07, 0.08, 0.09, or 0.1 mg to an upper limit of about 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0, 11.0, 12.0, 13.0, 14.0, 15.0, 16.0, 17.0, 18.0, 19.0 or 20.0 mg in a 24 hour period; and as much as 30, 40, 50, 60, 70, 80, 90, 100, 200, 300, 400, 500 mg or more over a prolonged period of time with a medical infusion pump (external or implanted) or similar device designed for delivery of a substance over a prolonged period. The frequency of administration can be one, two, three, four, five times or more per day or as necessary to control the condition. The duration of therapy depends on the type of condition being treated and can be for as long as the life of the subject. In humans, the United States Food and Drug Administration (FDA) defines the maximum recommended therapeutic dose (MRTD) as 0.00001 to 1000 mg/kg body weight per day (Contrera 2004); and this dose would be dependent on the route of administration (i.e., systemically vs. directly into the heart).

[0048] As used herein, a “pharmaceutically acceptable carrier” according to the present invention is a component such as a carrier, diluent, or excipient of a composition that is compatible with the other ingredients of the composition in that it can be combined without the loss of the activity of the agents or the compositions, is suitable for use in subjects as provided herein without undue adverse side effects (such as toxicity, irritation, allergic response, and death). Side effects are “undue” when their risk outweighs the benefit provided by the pharmaceutical composition. Non-limiting examples of pharmaceutically acceptable components include, without limitation, any of the standard pharmaceutical carriers such as phosphate buffered saline solutions, water, sterile water, polyethylene glycol, polyvinyl pyrrolidone, lecithin, arachis oil, sesame oil, emulsions such as oil/water emulsions or water/oil emulsions, micromul-
sions, and various types of wetting agents. Additives such as water, alcohols, oils, glycols, preservatives, flavoring agents, coloring agents, suspending agents, and the like may also be included in the composition along with the carrier, diluent, or excipient.

“Kit” as used herein refers to an assembly of components. The assembly of components can be a partial or complete assembly. Instructions for use of the kit or use of various components of the kit are optionally included.

As used herein, “administered at the time of” means that the ephrin or composition including an ephrin according to embodiments of the present invention is administered at a time sufficiently close to the onset of an impetus causing injury, a time sufficiently close to the onset of the actual injury or a time sufficiently close to the manifestation of physical symptoms characteristic of the injury. If administered at the time of injury, the ephrin or composition including an ephrin according to embodiments of the present invention may reduce injury or prevent further injury. “Administered after” means that the ephrin or composition including an ephrin according to embodiments of the present invention is administered after the onset of an impetus causing injury, after the onset of the actual injury or after the manifestation of physical symptoms characteristic of the injury. If administered after injury, the ephrin or composition including an ephrin according to embodiments of the present invention may reduce injury or prevent further injury. “Administered before” means that the ephrin or composition including an ephrin according to embodiments of the present invention is administered before the onset of an impetus causing injury, before the onset of the actual injury or before the manifestation of physical symptoms characteristic of the injury. If administered before, the ephrin or composition including an ephrin according to embodiments of the present invention may be used as a preventive treatment.

In view of the foregoing, embodiments according to the present invention relate to methods of reducing injury following cardiovascular disease in a subject in need thereof, comprising administering to the subject a therapeutically effective amount of an ephrin. That is, injury in the presence of a therapeutically effective amount of ephrin is less than that in the absence of ephrin or does not worsen substantially in the presence of ephrin thereby reducing the extent of injury that may occur following cardiovascular disease. In particular, embodiments, cardiovascular disease comprises myocardial infarction. In still other embodiments, the cardiovascular disease comprises heart failure, peripheral arterial disease or stroke.

Embodiments of the present invention address injury that may occur to the cardiovascular system, including the heart, arteries, veins, arterioles, venules, and capillaries. In some embodiments, the type of injury may include, but is not limited to, infarct size, necrosis, chamber dilation, wall thinning, inflammation, apoptotic cell death, autophagy, hypertrophy of remote myocardium, fibrosis, or a combination thereof.

According to embodiments of the present invention, the ephrin is administered at the time of the injury. In other embodiments, the ephrin is administered after the injury. In still other embodiments, the ephrin is administered before the injury.

In some embodiments of the present invention, the ephrin is administered to a subject believed to be at risk for injury to the cardiovascular system. In some embodiments, the subject is believed to be at risk for myocardial infarction. Subjects at risk for injury to the cardiovascular system or at risk for myocardial infarction can be determined by use of clinical parameters and/or assessments known to those skilled in the art of diagnosing and/or treating the same, for example, physical examinations, detection of signs and symptoms of heart disease, or myocardial infarction specifically, electrocardiogram, echocardiogram, chest X-ray, blood tests to detect cardiac biomarkers, etc.

Embodiments of the present invention further include methods of promoting myocardial repair following cardiovascular disease in a subject in need thereof, comprising administering to the subject a therapeutically effective amount of an ephrin. That is, injury to the myocardium may be repaired, e.g., reversed or maintained at the same or similar level in the presence of a therapeutically effective amount of ephrin compared to that observed in the absence of ephrin following cardiovascular disease. In particular, embodiments, the cardiovascular disease is myocardial infarction. The ephrins suitable for use in such embodiments of the present invention have been described previously herein.

In some embodiments of the present invention, myocardial repair can be an improvement or a decrease in infarct size, necrosis, apoptosis, autophagy, angiogenesis, remodeling, chamber dilation, wall thinning, inflammation, reduction in serum cardiac troponin I and/or other markers of cardiomyocyte degradation or a combination thereof.

In further embodiments of the present invention, the ephrin is administered at the time of the onset of heart disease. In still other embodiments, the ephrin is administered after the onset of heart disease.

According to further embodiments of the present invention, ephrins can be administered as an adjunct to (or in combination with) reperfusion therapy. In particular, ephrin therapy can be administered (a) at the time of injury, (b) at the time of reperfusion, (c) during reperfusion and/or (d) at the time of injury and during reperfusion. The ephrin may be administered from 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 30, 60, 90, 120, 180, 240, 300 or 360 minutes before the time of reperfusion, or the ephrin may be administered at any period of time from the time of injury before and up to the time of reperfusion. The ephrin may further be administered every 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, or 30 minutes or more during the first hour of reperfusion, or any number of times during the first hour of reperfusion. Alternatively, the ephrin may be administered via a slow release to provide a more constant dosage level of ephrin for a period of time such as days or weeks before, at the time of and during reperfusion.

Embodiments of the present invention further provide pharmaceutical compositions that comprise, consist essentially of or consist of an ephrin and a pharmaceutically acceptable carrier. The ephrin can be any ephrin as described herein. In some embodiments, the pharmaceutical composition includes at least one agent useful for treating myocardial infarction and/or reducing myocardial injury. Agents that may be useful in a combination therapy with an ephrin include, but are not limited to, thrombolytics, antiplatelet agents, anticoagulants, beta blockers, angiotensin-converting enzyme (ACE) inhibitors, 3-hydroxy-3-methylglutaryl (HMG)-CoA reductase inhibitors, glycosides, diuretics, aldosterone receptor modulators and further including agents such as statins, digoxin, SDF-1a, Thymosin B4, VEGF, IGF and those that promote progenitor cell homing to the site of
injury, enhance revascularization, and/or cell survival. Ephrins can be administered in combination with stem cell therapy to promote survival, adhesion, retention of transplanted cells. “In combination” means that the two agents, compounds and/or therapies are administered closely enough in time that the presence of one alters the biological effects of the other. The two may be administered simultaneously (i.e., concurrently) or sequentially. Simultaneous administration may be carried out by mixing prior to administration, or by administering at the same point in time but at different anatomic sites or using different routes of administration. Furthermore, the phrases “concurrent administration,” “administration in combination,” “simultaneous administration” or “administered simultaneously” can be employed interchangeably. Moreover, the pharmaceutical compositions of the present invention may be used and/or administered in the same manner as described herein for the use and administration of the ephrin.

[0060] Embodiments of the present invention also provide kits comprising a composition comprising, consisting essentially of or consisting of an ephrin in a pharmaceutically acceptable carrier and a container suitable for delivery of the composition by way of a parenteral delivery device. In some embodiments, the parenteral delivery device is an intramyocardial administration device. Instruments of containment are those that can be used to deliver, place, attach, or insert the ephrin into the myocardium, for example, an intramyocardial device for intramyocardial delivery of the ephrin to the subject. Such containers, or bags, may include, but are not limited to, vials, ampoules, tubes, capsules, bottles, syringes, and bags.

[0061] The ephrins described above can be formulated for administration in accordance with known pharmacy techniques. See, e.g., Remington: The Science and Practice of Pharmacy 20th Edition, Lippincott Williams & White, Baltimore, Md. (2000). In the manufacture of a pharmaceutical composition according to the present invention, the active agent (including the physiologically acceptable salts thereof) is typically admixed with, inter alia, an acceptable carrier. The carrier must, of course, be acceptable in the sense of being compatible with any other ingredients in the formulation and must not be deleterious to the patient. The carrier can be a solid or a liquid, or both, and is preferably formulated with the compound as a unit-dose formulation, for example, a tablet, which can contain from 0.01% to 95% or 96%, or any value between 0.01% and 99%, by weight of the active compound. One or more active compounds can be incorporated in the compositions of the invention, which can be prepared by any of the well-known techniques of pharmacy, comprising admixing the components, optionally including one or more accessory ingredients. Moreover, the carrier can be preservative free.

[0062] The formulations of the present invention can include those suitable for oral, rectal, topical, inhalation (e.g., via an aerosol) buccal (e.g., sub-lingual), vaginal, topical (i.e., both skin and mucosal surfaces, including airways surfaces), transdermal administration and parenteral or infusion (e.g., subcutaneous, intramuscular, intradermal, intraarticular, intrapleural, intraperitoneal, intrathecal, intracerebral, intracranially, intramyocardial, intraventricular or intravenous), although the most suitable route in any given case will depend on the nature and severity of the condition being treated and on the nature of the particular active compound which is being used.

[0063] Particular routes of parenteral administration include intravenous, intraarterial, intramyocardial injection, controlled, delayed release (implantable devices such as implanted infusion devices or pumps, for example, osmotic pumps, or using nanoparticles or other bioengineered materials and/or cells for sustained release.

[0064] Formulations suitable for oral administration can be presented in discrete units, such as capsules, cachets, lozenges, or tablets, each containing a predetermined amount of the active agent; as a powder or granules; as a solution or a suspension in an aqueous or non-aqueous liquid; or as an oil-in-water or water-in-oil emulsion. Such formulations can be prepared by any suitable method of pharmacy which includes bringing into association the active agent and a suitable carrier (which can contain one or more accessory ingredients as noted above). In general, the formulations of the invention are prepared by uniformly and intimately admixing the active agent with a liquid or finely divided solid carrier, or both, and then, if necessary, shaping the resulting mixture. For example, a tablet can be prepared by compressing or molding a powder or granules containing the active agent, optionally with one or more accessory ingredients. Compressed tablets can be prepared by compressing, in a suitable machine, the agent in a free-flowing form, such as a powder, granules optionally mixed with a binder, lubricant, inert diluent, and/or surface active dispersing agent(s). Molded tablets can be made by molding, in a suitable machine, the powdered agent moistened with an inert liquid binder.

[0065] Formulations of the present invention suitable for parenteral administration comprise sterile aqueous and non-aqueous injection solutions of the active agent, which preparations are preferably isotonic with the blood of the intended recipient. These preparations can contain, buffers and solutes which render the formulation isotonic with the blood of the intended recipient. Aqueous and non-aqueous sterile suspensions can include suspending agents and thickening agents. The formulations can be presented in unit-dose or multi-dose containers, for example sealed ampoules and vials, and can be stored in a freeze-dried (lyophilized) condition requiring only the addition of the sterile liquid carrier, for example, saline or water-for-injection immediately prior to use. Extemporaneous injection solutions and suspensions can be prepared from sterile powders, granules and tablets of the kind previously described.

[0066] For example, in some embodiments of the present invention, there is provided an injectable, stable, sterile composition comprising an active agent, or a salt thereof, in a unit dosage form in a sealed container. The agent or salt is provided in the form of a lyophylize which is capable of being reconstituted with a suitable pharmaceutically acceptable carrier to form a liquid composition suitable for injection thereof into a subject. The unit dosage form comprises from about 10 mg to about 10 grams of the agent or salt. When the agent or salt is substantially water-insoluble, a sufficient amount of emulsifying agent which is physiologically acceptable can be employed in sufficient quantity to emulsify the agent or salt in an aqueous carrier. Non-limiting examples of agents that contribute to the pharmaceutical acceptability of the compositions of the present invention include normal saline, phosphatidyl choline, and glucose. In some embodiments, the pharmaceutically acceptable carrier can be normal saline. In other embodiments, the pharmaceutically acceptable carrier can be normal saline with up to 0.0, 0.01, 0.02, 0.03, 0.04, 0.05, 0.06, 0.07, 0.08, 0.09, 1.0, 2.0,
3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, and 20%, and any value between 0.01% and 20%, glucose.

[0067] Formulations suitable for transdermal administration can be presented as discrete patches adapted to remain in intimate contact with the epidermis of the recipient for a prolonged period of time. Formulations suitable for transdermal administration can also be delivered by iontophoresis (see, for example, Pharmaceutical Research 3/6:S38 (1986)) and typically take the form of an optionally buffered aqueous solution of the active agent. Suitable formulations comprise citrate or histidine buffer (pH 6) or ethanol/water and contain from 0.1 to 0.2M active ingredient.

[0068] Further, the present invention provides liposomal formulations of the agents disclosed herein and salts thereof. The technology for forming liposomal suspensions is well known in the art. When the agent or salt thereof is an aqueous-soluble salt, using conventional liposome technology, the same can be incorporated into lipid vesicles. In such an instance, due to the water solubility of the agent or salt, the agent or salt will be substantially entrained within the hydrophilic center or core of the liposomes. The lipid layer employed can be of any conventional composition and can either contain cholesterol or can be cholesterol-free. When the agent or salt of interest is water-insoluble, again employing conventional liposome formation technology, the salt can be substantially entrained within the hydrophobic lipid bilayer which forms the structure of the liposome. In either instance, the liposomes which are produced can be reduced in size, as through the use of standard sonication and homogenization techniques.

[0069] The liposomal formulations containing the agents disclosed herein or salts thereof, can be lyophilized to produce a lyophilize which can be reconstituted with a pharmaceutically acceptable carrier, such as water, to regenerate a liposomal suspension.

[0070] In addition to active agents or their salts, the pharmaceutical compositions can contain other additives, such as pH-adjusting additives. In particular, useful pH-adjusting agents include acids, such as hydrochloric acid, bases or buffers, such as sodium lactate, sodium acetate, sodium phosphate, sodium citrate, sodium borate, or sodium gluconate. Further, the compositions can contain microbial preservatives. Suitable preservatives include methylparaben, propylparaben, and benzyl alcohol. The microbial preservative is typically employed when the formulation is placed in a vial designed for multidose use. The pharmaceutical compositions of the present invention can be lyophilized using techniques well known in the art.

[0071] In particular embodiments, the ephrin is administered via intramyocardial injection. In this instance, the needle may be inserted into the left ventricle above and to the right of the site of coronary ligation. It is advanced toward the border zone of infarcted to non-infarcted tissue, where the protein is then delivered and when the “bleb” that is formed dissipates, the needle may be slowly withdrawn.

[0072] In other embodiments, the ephrin is administered via single or repetitive intracoronary, intravenous, subcutaneous, or intraperitoneal route, which may be performed anytime during or after the injury or when the occlusion is removed and coronary flow is restored.

[0073] Subjects suitable to be treated according to the present invention include, but are not limited to, avian and mammalian subjects, and are preferably mammalian. Mammals of the present invention include, but are not limited to, canines, felines, bovines, caprines, equines, ovinates, porcines, rodents (e.g. rats and mice), lagomorphs, primates, humans, and the like, and mammals in utero. Any mammalian subject in need of being treated according to the present invention is suitable. Human subjects are preferred. Human subjects of both genders and at any stage of development (i.e., neonate, infant, juvenile, adolescent, adult) can be treated according to the present invention.

[0074] Illustrative avians according to the present invention include chickens, ducks, turkeys, geese, quail, pheasant, ratites (e.g., ostrich) and domesticated birds (e.g., parrots and canaries), and birds in ovo.

[0075] The present invention is primarily concerned with the treatment of human subjects, but the invention can also be carried out on animal subjects, particularly mammalian subjects such as mice, rats, dogs, cats, livestock and horses for veterinary purposes, and for drug screening and drug development purposes.

[0076] Suitable subjects additionally include subjects who are at risk for cardiovascular disease or have cardiovascular disease, those who are at risk for myocardial infarction or have suffered a myocardial infarction and/or those who are at risk for myocardial injury or have experienced myocardial injury including those suffering from or at risk for acute coronary events and those suffering from more long-term coronary disease such as congestive heart failure.

[0077] The present invention will now be described with reference to the following examples. It should be appreciated that these examples are for the purposes of illustrating aspects of the present invention, and do not limit the scope of the invention as defined by the claims.

Example 1

Methods

[0078] All procedures were approved by the East Carolina University Institutional Animal Care and Use Committee and the investigation conforms to the Guide for the Care and Use of Laboratory Animals published by the US National Institutes of Health (NIH Publication No. 85-23, revised 1996).

Animals

[0079] Six week old B6/129S breeder pairs were obtained from Jackson Laboratories (Bar Harbor, Me.) to establish an in-house colony (strain #101045). Animals were housed in 12-12 light/dark cycle conditions and received food and water ad libitum.

Surgical Procedure

[0080] Male 8-10 week old mice (22-28 g) were anesthetized (20 μl/g Avertin i.p.), intubated, and mechanically ventilated. The left anterior descending (LAD) coronary artery was permanently ligated using 8-0 suture. Sham controls in which the suture was pulled through the heart but not ligated, and either IgG-Fc or ephrin A1-Fc was injected, were done to ensure that there was no injury caused by the injection (data not shown). Infarction was confirmed by staining of the myocardium distal to the site of ligation. Following coronary occlusion, using a Hamilton syringe with a sterile 30 gauge needle, animals received a single intramyocardial injection of either 6 μg IgG-Fc (R&D #110-1G), or 6 μg ephrin A1-Fc (Sigma #E9902) resuspended in 6 μl sterile PBS at the peri-
Infarct zone. This dose was chosen based on prior studies showing effective doses of intramyocardial injections of TB4 (Bock-Marquette et al., 2004) and intraperitoneal injection of ephrinB2-Fc (Mansson-Broberg et al., 2008). Additionally, this dose is within the therapeutic range (for humans) of the maximum recommended therapeutic dose (MRTD) 0.00001 to 1000 mg/kg-bw/day, as defined by the FDA (Contrera et al., 2004). Taking into account heart weight, potential for eflux of the protein from the heart via the injection site, and that an average mouse left ventricle weighs approximately 150 mg, injecting 6 μg of protein intramyocardially is within this range (approximately 40 mg/kg). The investigator performing the surgery was blinded as to the treatment, which were randomized by another investigator. Once the animals recovered, they were returned to the vivarium. The surgical procedure is described in more detail elsewhere (Virag & Murry, 2003; Virag et al., 2010).

EphrinA1-Fc Distribution in the Myocardium

To determine the distribution pattern and duration of persistence of ephrinA1-Fc in the nonperfused myocardium, an anti-human IgG-Fc was used to immunolocalize the ephrinA1 chimeras in hearts at 30 min, 4 hr, and 24 hr post-injection (n=3 per group). A representative image (FIG. 1) shows prominent epicardial and transmural staining at 30 min. Light staining was observed in 2 of 3 hearts at 4 hr but none was observed at 24 hr or 4 days post injection, saline injected hearts, or in tissues incubated without the primary antibody (data not shown).

Histology and Morphometry

Images of four haematoxylin and eosin-stained sections per heart were taken at 20x magnification using a DP70 digital camera. Two sections of infarct, approximately 1 mm apart (apical and closer to the ligation site) and two sections of base in non-infarcted regions, also 1 mm apart, were used. Scion imaging software (Scion Corporation, Frederick, Md., USA) was used to trace the cross sectional area of the left ventricular wall and chamber, as well as the infarct zone (necrosis+granulation tissue) and necrosis. Measurements from three to four complete, transverse profiles per heart were averaged. Septal and free wall thicknesses were also measured using the average of three radial measures in each of two sections containing infarct. The investigator was blinded as to the treatment while obtaining morphometric measurements. After determining that there was no significant difference between IgG-Fc-treated hearts and standard day-infarcted hearts without any injection, we used 4 day MI hearts for protein and RNA analysis, and this experimental group is labelled as MI rather than IgG-Fc, which was the group used for histological and immunohistochemical analysis.

Immunostaining

Tissue sections were deparaffinized in xylene and endogenous peroxidases quenched with 3% H2O2 in methanol. Slides were rinsed in PBS and incubated with anti-ephrinA1 (Zymed #34-3300), CD45 (Pharmingen, #550539; 1:2000) for leukocytes, Ly6G (Pharmingen #550291) for neutrophils, or CD31 (Pharmingen #553371) and anti-BrDU (Roche #1158586001) for proliferating endothelial cells. Slides were incubated with appropriate biotinylated secondary antibodies and then with Avidin Biotin Complex (Vector Labs PK-6100). The reaction product was visualized with DAB (Vector, SK-4100), counterstained with methyl green, dehydrated in xylene, and slides were coverslipped. For the ephrinA1 staining, a second antibody, anti-ephrinA1 (Santa Cruz, sc-911) was used to verify consistent staining pattern. Negative controls were performed in the same manner but without a primary antibody. For mast cell staining, slides were sent to Histos-Scientific Research Laboratories (Mount Jackson, Va.) for pinacolyn ethylindamine staining to identify mast cells (Murray et al., 2004). Leukocyte, neutrophil, and mast cell density was measured in 3 fields per section of 2 sections of infarcted heart at 400x. Results were expressed as the number of cells per 0.1 mm2. For proliferating endothelial cells (BrDU+/CD31+), numbers are expressed as a percentage of 1000 endothelial cells (CD31+ only).

Cardiac Troponin I (cTnI) Measurements

Approximately 50-100 μl of whole blood was collected from mice pre-surgery and at the time of euthanasia by a submandibular bleed, stored in lithium heparin coated tubes on a rocker to prevent clotting, and analyzed within 30 minutes of collection on an i-STAT Handheld Clinical Analyzer with cTnl cartridges (Abbott Labs). Values are expressed as nanograms per milliliter.

Protein Isolation

Whole left ventricles (LV) were snap frozen in liquid nitrogen at the time of collection, and stored at ~80°C until use. The whole LV was homogenized in a lysis buffer containing 50 mM Hepes, 10 mM EDTA, 100 mM NaF, 50 mM Na pyrophosphate, and 1% each of protease and phosphatase inhibitors. Protein was quantified using the Bradford Assay.

Western Blotting

Western blotting was performed on a 4-12% gradient Bis-Tris gel (BioRad) in 1xMOPS running buffer. 50 μg of sample was loaded per well, and the gel was run for 1 hour at 155V, and transferred for 55 minutes (for ephrinA1, BAG-1 and GAPDH) or 1 hr 30 min (for cleaved PARP, AKT, and pAKT) onto pure nitrocellulose membranes (BioRad). The membrane was incubated with one of the following antibodies: cleaved PARP (89 kDa; Cell Signaling #9544; 1:1000), ephrinA1 (28 kDa; Santa Cruz, sc-911; 1:1000), AKT (Cell Signaling #4691; 1:1000), phospho-AKT (Cell Signaling #4060; 1:2000), and GAPDH (37 kDa; Millipore #MAB374; 1:100), followed by appropriate secondary antibodies. EphrinA1 and cleaved PARP were run on the same membrane, which was cut horizontally at 50 kDa, with the bottom half of the membrane used for the ephrinA1 blot, and the top half used for the cleaved PARP blot. The ephrinA1 blot was then
stripped/reprobed for anti-GAPDH to confirm equal protein loading. All blots were detected with Amersham ECL Advance (GE Healthcare #RPN2135) and imaged on a Typhoon Imager. Densitometry was performed using Image J software and the intensity of each protein was normalized to GAPDH. In the case of pAKT/AKT, the amount of phosphorylated AKT protein was normalized to total AKT.

RNA Extraction and Real-Time RT-PCR

The Trizol method was used for RNA isolation, followed by the Quiagen RNeasy kit for additional purification. cDNA was synthesized using a high capacity cDNA kit. Real-time RT-PCR was conducted on an Applied Biosystems thermocycler. A reaction mixture of 10 μl containing 100 ng RNA was amplified using recommended conditions for TaqMan primers provided by Applied Biosciences. TaqMan primers and probes were obtained from Applied Biosciences (EphrinA1: Mm00438636_m1, EphA1: Mm00445804_m1, EphA2: Mm00438726_m1, EphA3: Mm00580743_m1, EphA4: Mm00433056_m1, EphA5: Mm00433074_m1, EphA6: Mm00433094_m1, EphA7: Mm00833876_m1, GAPDH: Mm9999915_g1). In each experiment, fluorescence data were analyzed using the ΔΔCT method. Gene expression was normalized to the housekeeping gene GAPDH. No Template Controls (NTC) were included in each experiment, and all samples were run in triplicate.

Statistics

Student t-tests were used to test statistical significance between 4 day MI and ephrinA1-Fc-treated MI for RT-PCR, relative infarct size, and necrosis. ANOVAs and student Newman-Keuls post-hoc analyses were used to determine differences between control, 4 day MI, and ephrinA1-Fc-treated MI for cTnI, inflammatory cell density, chamber area, and left ventricular free wall thickness. The number of hearts analyzed for each endpoint and significance levels have been specified for each experiment in reference to the figures. Four animals were excluded from all experiments: two from each group, based on suboptimal cTnI and/or overall health of the animals.

Example 2

EphrinA1-Fc Reduces Infarct Size, Necrosis, Chamber Dilatation, and Left Ventricular Free Wall Thinning

EphrinA1-Fc or IgG-Fc was injected into the border zone of the infarct immediately after coronary ligation. Four days after surgery, tissue was collected and either fixed for histology and immunohistochemistry, or frozen for RNA and protein isolation. Overall survival for this study was 70%, and there was no difference in survival between experimental groups. Histological staining and morphometric analyses (Fig. 2) show a 50% reduction in the size of the infarct (expressed as a percent of the left ventricle), 64% less necrotic area, a 35% reduction in chamber dilatation, and 32% less thinning of the infarcted left ventricular free wall. There was no significant difference in chamber area between uninjured control hearts and those treated with ephrinA1-Fc at day 4 post-MI.

Example 3

Cardiac Troponin I Levels Reduced with ephrinA1-Fc Administration

Serum cTnI levels were measured prior to surgery and at the time of euthanasia (four days post-MI) in the same animals. There was an 89% increase in cTnI levels following MI in vehicle treated hearts. However, cTnI levels in ephrinA1-Fc treated hearts were 54% lower than those from vehicle treated animals (FIG. 3A). There was no significant difference between pre-surgery levels and those of ephrinA1-Fc treated animals four days post-surgery.

Example 4

EphrinA1-Fc Treated Hearts Show Diminished Cleaved PARP Expression and Increased BAG-1 Expression

Cleaved PARP, the main target of caspase-3 and an indicator of increased apoptosis (Nicholson et al., 1995; Tewari et al., 1995; Oliver et al., 1998), increased by approximately 88% in response to MI, but diminished with ephrinA1-Fc treatment (FIG. 3B) below control levels. Although we did not observe a change in the level of Bcl-2 protein expression with ephrinA1-Fc treatment (data not shown), we did observe a change in Bcl-2-associated athanogene-1 (BAG-1). BAG-1 is a protein that enhances the anti-apoptotic effects of Bcl-2 and has also been identified as a cardioprotective protein through interactions with heat shock proteins (Doong et al., 2002; Townsend et al., 2004). EphrinA1-Fc administration upregulated the expression of the BAG-1 protein by approximately 54% (FIG. 3C).

Example 5

EphrinA1-Fc Treatment Reduces Inflammatory Cell Infiltration to Infarcted Myocardium

Results indicate a 57% reduction in neutrophil density (FIG. 4A) and a 21% reduction in leukocyte density in ephrinA1-Fc-treated versus IgG-Fc-treated hearts at 4 days post-MI (FIG. 4B), indicating ephrinA1-Fc attenuates the inflammatory response. No statistical differences were observed in the numbers of mast cells between ephrinA1-Fc and vehicle treated hearts, with only a few (1-6 per section of LV) mast cells per heart (data not shown).

Example 6

EphrinA1-Fc Treatment Does Not Influence the Angiogenic Response to MI

No differences were seen in endothelial cell proliferation (5.0±1% vs. 6.1±1.3%; n=3 vehicle, n=5 ephrinA1-Fc) or capillary density (111±26.4 vs. 111±26.0 vessels per 40x high power field, n=4 per group) between vehicle- and ephrinA1-Fc-treated hearts, respectively.

Example 7

EphrinA1 and EphA Receptor Gene Expression in Response to EphrinA1-Fc Treatment

EphrinA1 gene expression was quantified using qRT-PCR, mRNA levels decrease significantly by 35% following MI, and remain unchanged with ephrinA1-Fc treat-
ment (FIG. 5). Of the eight receptors, EphA1, A2, A3, and A7 were all significantly upregulated four days after MI (5-fold, 2-fold, 5-fold, and 28%, respectively); EphA1 and A2 were further upregulated with ephrinA1-Fc treatment (10-fold and 3-fold, respectively, from control). Despite not changing in response to MI, EphA4 was significantly upregulated 2-fold with ephrinA1-Fc treatment. EphA6 was detected in control hearts, but significantly decreased in response to MI, and expression in the ephrinA1-Fc-treated group was unchanged relative to the untreated MI group (FIG. 5). Ligands ephrinA2-A5 and EphrinB3 (the only B ligand known to bind to an EphA receptor, specifically, EphA4) were also detected in the heart, but their expression did not change in response to MI or ephrinA1-Fc administration (data not shown).

Example 8

**Endogenous EphrinA1 Tissue Expression Pattern post-MI and in Response to EphrinA1-Fc Treatment**

[0096] In uninjured control hearts, endogenous ephrinA1 protein expression appeared to be expressed at a low, basal level on cardiac myocytes throughout the myocardium (FIGS 6A and D). Four days after MI, ephrinA1 protein expression was expressed in cardiomyocytes throughout the uninjured regions of the hearts and was also localized to the spared cardiac myocytes on both the epicardial and endocardial surfaces of the myocardium, at the border zones of the infarct (FIGS. 6B and 6E). In the ephrinA1-Fc-treated hearts at 4 days post-MI, endogenous ephrinA1 protein expression appeared to be localized not only to the cardiomyocytes, but also to infiltrating granulation tissue cells throughout the infarct zone (FIGS. 6C and F).

Example 9

**EphrinA1 Protein Expression Post-MI and in Response to EphrinA1-Fc Treatment**

[0097] Western blotting was used to quantify endogenous ephrinA1 expression. Since anti-IgG-Fc immunostaining (FIG. 1) shows that expression of the chimeric protein is greatly reduced by 4 hours post-injection, and completely abolished by 24 hours, ephrinA1 protein expression detected at 4 days is only the endogenous protein. In addition, the molecular weight for the chimera is 42 kDa (not observed), vs. 28 kDa for the native protein. Endogenous ephrinA1 protein expression decreased 50% with MI, but was only diminished by approximately 36% with ephrinA1-Fc treatment (FIG. 6C).

Example 10

**EphrinA1-Fc Administration Increases pAKT/Total AKT Ratio**

[0098] Total and phosphorylated AKT protein was measured using western blotting. While total AKT remained unchanged in the three groups (Control, 4 day MI, and EphrinA1-Fc treated), phosphorylated AKT levels increased with EphrinA1-Fc treatment following MI (FIG. 7A). The AKT/ AKT ratio was significantly higher in the MI group compared to control, and further increased in EphrinA1-Fc-treated hearts compared to both control and MI.

Example 11

**NF-κB p65 Protein Reduced with EphrinA1-fc Administration**

[0099] Protein levels of nuclear factor κ light-chain enhancer of activated B cells (NF-κB) were measured with Western blotting, and a trend for reduced expression of this immune-modulatory protein with ephrinA1-Fc administration was observed (FIG. 7B).

Example 12

Comparison of Infarct Size in Reperfused Versus Nonreperfused Myocardium

[0100] Currently, reperfusion is the only treatment known to improve longevity in patients with acute myocardial infarction. Reperfusion can accelerate phagocytic resorption of necrotic myocardium and expedite its replacement with granulation tissue, thus reducing remodeling. However, this therapy is generally applied within 6 hours following the occlusive event in order to salvage any of the highly ischemia-sensitive myocardial tissue. The therapeutic efficacy of reperfusion generally declines exponentially within hours of occlusion onset, causes additional oxidative stress and, if flow is not restored, infarct injury proceeds and accelerates, with poor long-term prognosis.

[0101] This experiment is designed to compare the infarct size in reperfused versus nonreperfused myocardium following 1) sham operation, 2) intramyocardial IgG-Fc administration, 3) intramyocardial ephrinA1-Fc injection, and 4) an intravenous (i.v.) injection of ephrinA1-Fc. The following table illustrates the groups and number of mice needed for each (assuming at least 85% survival).

**Experiment #1:**

<table>
<thead>

*additional to existing data sets (Dries et al. (2011) J. Physiol.: 589: 1725-1740)

[0103] Baseline serum troponin I (TnI) is measured prior to surgery and again prior to sacrifice as an index of myocardial damage. Similarly, baseline cardiac function (fractional shortening, ejection fraction, LV mass, and systolic and diastolic dimensions) of each animal prior to surgery and again prior to sacrifice is performed using echocardiographic analysis. In control animals and at the time of sacrifice of the experimental animals, in vivo pressure-volume analysis (HR, ESHB, EDBP, ESV, EDV, SV, EF+/−dP/dt) is performed via catheterization using a 1.4 Fr conductance catheter. Animals are given an intraperitoneal injection of isoproterenol (0.25 mg/kg) to assess their contractile reserve in response to acute cardiovascular stress. ECG recordings are obtained and arrhythmia scores are be generated. Histologic examination and morphometric analyses are be performed to measure...
differences in infarct size, composition (necrosis and granulation tissue), and ventricular dimensions (septal and free wall thickness).

Example 13

Presence of EphrinA1-Fc in the Myocardium Relative to the Area at Risk During Intravenous Administration Compared to Intramyocardial Administration

[0104] Immunohistochemistry is used to evaluate the presence and distribution of ephrinA1-Fc in the heart relative to the area at risk (TTC staining) when administered intravenously compared to intramyocardial injection. EphrinA1-Fc is administered intramyocardially or with an i.v. injection at the time of ligation in mice and the table below describes the experimental groups and numbers of mice in each group.

<table>
<thead>
<tr>
<th>Experimental Groups</th>

<212> TYPE: PRT
<213> ORGANISM: Homo sapiens
What is claimed is:

1. A pharmaceutical composition comprising:
   an ephrin; and
   a pharmaceutically acceptable carrier.

2. The pharmaceutical composition of claim 1, wherein the pharmaceutical composition is a parenteral composition.

3. The pharmaceutical composition of claim 2, wherein the parenteral composition is selected from the group consisting of a subcutaneous, intramuscular, intradermal, intraarticular, intrapleural, intraperitoneal, intrathecal, intracerebral, intracranially, intramyocardial, intraarterial and intravenous composition.

4. The pharmaceutical composition of claim 3, wherein the parenteral composition is an intravenous composition.

5. The pharmaceutical composition of claim 3, wherein the parenteral composition is an intramyocardial composition.

6. The pharmaceutical composition of claim 3, wherein the parenteral composition is a subcutaneous composition.

7. The pharmaceutical composition of claim 1, wherein the pharmaceutical composition is a controlled or delayed release composition.

8. The pharmaceutical composition of claim 7, wherein the controlled or delayed release composition is an implantable composition.

9. The pharmaceutical composition of claim 7, wherein the controlled or delayed release composition is a nanoparticle composition.

10. The pharmaceutical composition of claim 1, wherein the ephrin is an ephrin-A class ephrin.

11. The pharmaceutical composition of claim 1, wherein the ephrin is ephrin A1, ephrin A2, ephrin A3, ephrin A4, ephrin A5, or a combination thereof.

12. The pharmaceutical composition of claim 1, wherein the ephrin is ephrin A1.

13. The pharmaceutical composition of claim 1, wherein the ephrin comprises ephrin A1-Fc.

14. The pharmaceutical composition of claim 1 further comprising an agent useful for treating myocardial infarction.

15. A kit comprising a composition comprising an ephrin in a pharmaceutically acceptable carrier and a container suitable for delivery of the composition into a parenteral administration device optionally comprising instructions for use of the components of the kit.

16. The kit of claim 15, wherein the parenteral administration device is an intramyocardial administration device.

17. The kit of claim 15, wherein the ephrin is an ephrin A class ephrin.

18. The kit of claim 15, wherein the ephrin is ephrin A1, ephrin A2, ephrin A3, ephrin A4, ephrin A5, or a combination thereof.

19. The kit of claim 15, wherein the ephrin is ephrin A1.

20. The kit of claim 15, wherein the ephrin comprises ephrin A1-Fc.
