Title: AXMI205 VARIANT PROTEINS AND METHODS FOR THEIR USE

Abstract: Compositions and methods for conferring pesticidal activity to bacteria, plants, plant cells, tissues and seeds are provided. Compositions comprising a coding sequence for pesticidal polypeptides are provided. The coding sequences can be used in DNA constructs or expression cassettes for transformation and expression in plants and bacteria. Compositions also comprise transformed bacteria, plants, plant cells, tissues, and seeds. In particular, isolated pesticidal nucleic acid molecules are provided. Additionally, amino acid sequences corresponding to the polynucleotides are encompassed. In particular, the present invention provides for nucleic acid molecules comprising nucleotide sequences encoding the amino acid sequence shown in SEQ ID NO:7, 8, 9, 10, 11, or 12, the nucleotide sequence set forth in SEQ ID NO:4, 5, or 6, as well as variants and fragments thereof.
AXMI205 VARIANT PROTEINS AND METHODS FOR THEIR USE

CROSS REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of U.S. Provisional Application Serial No. 61/512,539, filed July 28, 2011, the contents of which are herein incorporated by reference in their entirety.

REFERENCE TO SEQUENCE LISTING SUBMITTED ELECTRONICALLY

The official copy of the sequence listing is submitted electronically via EFS-Web as an ASCII formatted sequence listing with a file named "APA116029SEQLIST.TXT", created on July 19, 2012, and having a size of 45.8 kilobytes and is filed concurrently with the specification. The sequence listing contained in this ASCII formatted document is part of the specification and is herein incorporated by reference in its entirety.

FIELD OF THE INVENTION

This invention relates to the field of molecular biology. Provided are variant pesticidal proteins having activity against rootworm pests. These proteins and the nucleic acid sequences that encode them are useful in preparing pesticidal formulations and in the production of transgenic rootworm-resistant plants.

BACKGROUND OF THE INVENTION

Introduction of DDT (dichloro-diphenyl-trichloroethane) and the following move towards indiscriminate use of synthetic chemical insecticides led to the contamination of water and food sources, poisoning of non-target beneficial insects and development of insect pests resistant to the chemical insecticides. Increased public concerns about the adverse environmental effects of indiscriminate use of chemical insecticides prompted a search for alternative methods for insect pest control.

One of the promising alternatives has been the use of biological control agents. There is well-documented history of safe application of Bt (B. thuringiensis, a gram positive soil bacterium) as effective biopesticides and a number of reports of
expression of delta-endotoxin gene(s) in crop plants are available. Only a few insecticidal sprays are required on Bt transgenic crops, which not only save cost and time, but also reduce health risks. In some cases, insects can develop resistance to different insecticidal compounds, which raises the need to identify alternative biological control agents for pest control.

SUMMARY OF INVENTION

Compositions and methods for conferring pesticidal activity to bacteria, plants, plant cells, tissues and seeds are provided. Compositions include nucleic acid molecules encoding sequences for pesticidal and insecticidal polypeptides, vectors comprising those nucleic acid molecules, and host cells comprising the vectors. Compositions also include the pesticidal polypeptide sequences and antibodies to those polypeptides. The nucleotide sequences can be used in DNA constructs or expression cassettes for transformation and expression in organisms, including microorganisms and plants. The nucleotide or amino acid sequences may be synthetic sequences that have been designed for expression in an organism including, but not limited to, a microorganism or a plant. Compositions also comprise transformed bacteria, plants, plant cells, tissues, and seeds.

In particular, isolated or recombinant nucleic acid molecules are provided that encode a pesticidal protein. Additionally, amino acid sequences corresponding to the pesticidal protein are encompassed. In particular, the present invention provides for an isolated nucleic acid molecule comprising a nucleotide sequence encoding the amino acid sequence shown in SEQ ID NO:7, 8, 9, 10, 11, or 12 or a nucleotide sequence set forth in SEQ ID NO:4, 5, or 6, as well as variants and fragments thereof.

Nucleotide sequences that are complementary to a nucleotide sequence of the invention, or that hybridize to a sequence of the invention are also encompassed.

Methods are provided for producing the polypeptides of the invention, and for using those polypeptides for controlling or killing a lepidopteran, coleopteran, nematode, or dipteran pest. Methods and kits for detecting the nucleic acids and polypeptides of the invention in a sample are also included.

The compositions and methods of the invention are useful for the production of organisms with enhanced pest resistance or tolerance. These organisms and compositions comprising the organisms are desirable for agricultural purposes. The compositions of the invention are also useful for generating altered or improved
proteins that have pesticidal activity, or for detecting the presence of pesticidal proteins or nucleic acids in products or organisms.

DETAILLED DESCRIPTION

The present invention is drawn to compositions and methods for regulating pest resistance or tolerance in organisms, particularly plants or plant cells. By "resistance" is intended that the pest (e.g., insect) is killed upon ingestion or other contact with the polypeptides of the invention. By "tolerance" is intended an impairment or reduction in the movement, feeding, reproduction, or other functions of the pest. The methods involve transforming organisms with a nucleotide sequence encoding a pesticidal protein of the invention. In particular, the nucleotide sequences of the invention are useful for preparing plants and microorganisms that possess pesticidal activity. Thus, transformed bacteria, plants, plant cells, plant tissues and seeds are provided. Compositions are pesticidal nucleic acids and proteins of bacterial species. The sequences find use in the construction of expression vectors for subsequent transformation into organisms of interest, as probes for the isolation of other homologous (or partially homologous) genes, and for the generation of altered pesticidal proteins by methods known in the art, such as domain swapping or DNA shuffling. The proteins find use in controlling or killing lepidopteran, coleopteran, dipteran, and nematode pest populations and for producing compositions with pesticidal activity.

By "pesticidal toxin" or "pesticidal protein" is intended a toxin that has toxic activity against one or more pests, including, but not limited to, members of the Lepidoptera, Diptera, and Coleoptera orders, or the Nematoda phylum, or a protein that has homology to such a protein. Pesticidal proteins have been isolated from organisms including, for example, Bacillus sp., Clostridium bifermentans and Paenibacillus popilliae. Pesticidal proteins include amino acid sequences deduced from the full-length nucleotide sequences disclosed herein, and amino acid sequences that are shorter than the full-length sequences, either due to the use of an alternate downstream start site, or due to processing that produces a shorter protein having pesticidal activity. Processing may occur in the organism the protein is expressed in, or in the pest after ingestion of the protein.

Thus, provided herein are novel isolated or recombinant nucleotide sequences that confer pesticidal activity. Also provided are the amino acid sequences of the
pesticidal proteins. The protein resulting from translation of this gene allows cells to control or kill pests that ingest it.

Isolated Nucleic Acid Molecules, and Variants and Fragments Thereof

One aspect of the invention pertains to isolated or recombinant nucleic acid molecules comprising nucleotide sequences encoding pesticidal proteins and polypeptides or biologically active portions thereof, as well as nucleic acid molecules sufficient for use as hybridization probes to identify nucleic acid molecules encoding proteins with regions of sequence homology. As used herein, the term "nucleic acid molecule" is intended to include DNA molecules (e.g., recombinant DNA, cDNA or genomic DNA) and RNA molecules (e.g., mRNA) and analogs of the DNA or RNA generated using nucleotide analogs. The nucleic acid molecule can be single-stranded or double-stranded, but preferably is double-stranded DNA.

An "isolated" nucleic acid sequence (or DNA) is used herein to refer to a nucleic acid sequence (or DNA) that is no longer in its natural environment, for example in an in vitro or in a recombinant bacterial or plant host cell. In some embodiments, an "isolated" nucleic acid is free of sequences (preferably protein encoding sequences) that naturally flank the nucleic acid (i.e., sequences located at the 5' and 3' ends of the nucleic acid) in the genomic DNA of the organism from which the nucleic acid is derived. For purposes of the invention, "isolated" when used to refer to nucleic acid molecules excludes isolated chromosomes. For example, in various embodiments, the isolated nucleic acid molecule encoding a pesticidal protein can contain less than about 5 kb, 4 kb, 3 kb, 2 kb, 1 kb, 0.5 kb, or 0.1 kb of nucleotide sequences that naturally flank the nucleic acid molecule in genomic DNA of the cell from which the nucleic acid is derived. A pesticidal protein that is substantially free of cellular material includes preparations of protein having less than about 30%, 20%, 10%, or 5% (by dry weight) of non-pesticidal protein (also referred to herein as a "contaminating protein").

Nucleotide sequences encoding the proteins of the present invention include the sequence set forth in SEQ ID NO:4, 5, or 6, and variants, fragments, and complements thereof. By "complement" is intended a nucleotide sequence that is sufficiently complementary to a given nucleotide sequence such that it can hybridize to the given nucleotide sequence to thereby form a stable duplex. The corresponding
amino acid sequence for the pesticidal protein encoded by this nucleotide sequence are set forth in SEQ ID NO:7, 8, 9, 10, 11, or 12.

Nucleic acid molecules that are fragments of these nucleotide sequences encoding pesticidal proteins are also encompassed by the present invention. By "fragment" is intended a portion of the nucleotide sequence encoding a pesticidal protein. A fragment of a nucleotide sequence may encode a biologically active portion of a pesticidal protein, or it may be a fragment that can be used as a hybridization probe or PCR primer using methods disclosed below. Nucleic acid molecules that are fragments of a nucleotide sequence encoding a pesticidal protein comprise at least about 50, 100, 200, 300, 400, 500, 600, 700, 800, 900, 1000, 1100, 1200, 1300, 1350, 1400, 1450, 1500, 1550, 1600 contiguous nucleotides, or up to the number of nucleotides present in a full-length nucleotide sequence encoding a pesticidal protein disclosed herein, depending upon the intended use. By "contiguous" nucleotides is intended nucleotide residues that are immediately adjacent to one another. Fragments of the nucleotide sequences of the present invention will encode protein fragments that retain or increase the biological activity of the pesticidal protein and, hence, retain or increase pesticidal activity relative to the pesticidal activity of Axmi205 (SEQ ID NO:2). By "retains activity" is intended that the fragment will have at least about 30%, at least about 50%, at least about 70%, 80%, 90%, 95% or higher of the pesticidal activity of the pesticidal protein. By "improved activity" is intended an increase of at least about 10%, at least about 15%, at least about 20%, at least about 25%, at least about 30%, at least about 35%, at least about 40%, at least about 50%, 60%, 70%, 80%, 90%, or higher, or at least about 1.5-fold, at least about 2-fold, at least about 2.5-fold, at least about 3-fold or higher increase in the pesticidal activity of the variant protein relative to the pesticidal activity of Axmi205. In some embodiments, the improvement consists of a decrease in the LC50 relative to the LC50 of Axmi205, e.g., a decrease of at least about 10%, at least about 20%, at least about 30%, at least about 40%, at least about 50%, at least about 55%, at least about 60%, or greater reduction in the LC50.

In various embodiments, the activity is lepidopteran activity. In some embodiments, the activity is rootworm activity, e.g., Western corn rootworm. Methods for measuring pesticidal activity are well known in the art. See, for example, Czapla and Lang (1990) *J. Econ. Entomol.* 83:2480-2485; Andrews et al. (1988) *Biochem. J.* 252:199-206; Marrone et al. (1985) *J. of Economic Entomology*
A fragment of a nucleotide sequence encoding a pesticidal protein that encodes a biologically active portion of a protein of the invention will encode at least about 15, 25, 30, 50, 75, 100, 125, 150, 175, 200, 250, 300, 350, 400, 450, 500, 550, or 600 contiguous amino acids, or up to the total number of amino acids present in a full-length pesticidal protein of the invention. In some embodiments, the fragment is an N-terminal or a C-terminal truncation of at least about 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 25 or more amino acids relative to SEQ ID NO:7, 8, 9, 10, 11, or 12. In some embodiments, the fragments encompassed herein result from the removal of the C-terminal 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 25 or more amino acids, e.g., by proteolysis or by insertion of a stop codon in the coding sequence.

Preferred pesticidal proteins of the present invention are encoded by a nucleotide sequence sufficiently identical to the nucleotide sequence of SEQ ID NO:4, 5, or 6. By "sufficiently identical" is intended an amino acid or nucleotide sequence that has at least about 60% or 65% sequence identity, about 70% or 75% sequence identity, about 80% or 85% sequence identity, about 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99% or greater sequence identity compared to a reference sequence using one of the alignment programs described herein using standard parameters. One of skill in the art will recognize that these values can be appropriately adjusted to determine corresponding identity of proteins encoded by two nucleotide sequences by taking into account codon degeneracy, amino acid similarity, reading frame positioning, and the like.

To determine the percent identity of two amino acid sequences or of two nucleic acids, the sequences are aligned for optimal comparison purposes. The percent identity between the two sequences is a function of the number of identical positions shared by the sequences (i.e., percent identity = number of identical positions/total number of positions (e.g., overlapping positions) x 100). In one embodiment, the two sequences are the same length. In another embodiment, the comparison is across the entirety of the reference sequence (e.g., across the entirety of one of SEQ ID NO:4, 5, or 6, or across the entirety of one of SEQ ID NO:7, 8, 9, 10, 11, or 12). The percent identity between two sequences can be determined using
techniques similar to those described below, with or without allowing gaps. In calculating percent identity, typically exact matches are counted.

The determination of percent identity between two sequences can be accomplished using a mathematical algorithm. A nonlimiting example of a mathematical algorithm utilized for the comparison of two sequences is the algorithm of Karlin and Altschul (1990) *Proc. Natl. Acad. Sci. USA* 87:2264, modified as in Karlin and Altschul (1993) *Proc. Natl. Acad. Sci. USA* 90:5873-5877. Such an algorithm is incorporated into the BLASTN and BLASTX programs of Altschul *et al.* (1990) *J. Mol. Biol.* 215:403. BLAST nucleotide searches can be performed with the BLASTN program, score = 100, wordlength = 12, to obtain nucleotide sequences homologous to pesticidal-like nucleic acid molecules of the invention. BLAST protein searches can be performed with the BLASTX program, score = 50, wordlength = 3, to obtain amino acid sequences homologous to pesticidal protein molecules of the invention. To obtain gapped alignments for comparison purposes, Gapped BLAST (in BLAST 2.0) can be utilized as described in Altschul *et al.* (1997) *Nucleic Acids Res.* 25:3389. Alternatively, PSI-Blast can be used to perform an iterated search that detects distant relationships between molecules. See Altschul *et al.* (1997) *supra*. When utilizing BLAST, Gapped BLAST, and PSI-Blast programs, the default parameters of the respective programs (e.g., BLASTX and BLASTN) can be used. Alignment may also be performed manually by inspection.

Another non-limiting example of a mathematical algorithm utilized for the comparison of sequences is the ClustalW algorithm (Higgins *et al.* (1994) *Nucleic Acids Res.* 22:4673-4680). ClustalW compares sequences and aligns the entirety of the amino acid or DNA sequence, and thus can provide data about the sequence conservation of the entire amino acid sequence. The ClustalW algorithm is used in several commercially available DNA/amino acid analysis software packages, such as the ALIGNX module of the Vector NTI Program Suite (Invitrogen Corporation, Carlsbad, CA). After alignment of amino acid sequences with ClustalW, the percent amino acid identity can be assessed. A non-limiting example of a software program useful for analysis of ClustalW alignments is GENEDOC™. GENEDOC™ (Karl Nicholas) allows assessment of amino acid (or DNA) similarity and identity between multiple proteins. Another non-limiting example of a mathematical algorithm utilized for the comparison of sequences is the algorithm of Myers and Miller (1988) *CABIOS* 4:11-17. Such an algorithm is incorporated into the ALIGN program (version 2.0),
which is part of the GCG Wisconsin Genetics Software Package, Version 10 
(available from Accelrys, Inc., 9685 Scranton Rd., San Diego, CA, USA). When 
utilizing the ALIGN program for comparing amino acid sequences, a PAM120 weight 
residue table, a gap length penalty of 12, and a gap penalty of 4 can be used.

Unless otherwise stated, GAP Version 10, which uses the algorithm of 
Needleman and Wunsch (1970) J. Mol. Biol 48(3):443-453, will be used to determine 
sequence identity or similarity using the following parameters: % identity and % 
similarity for a nucleotide sequence using GAP Weight of 50 and Length Weight of 3, 
and the nwsgapdna.cmp scoring matrix; % identity or % similarity for an amino acid 
sequence using GAP weight of 8 and length weight of 2, and the BLOSUM62 scoring 
program. Equivalent programs may also be used. By "equivalent program" is 
intended any sequence comparison program that, for any two sequences in question, 
generates an alignment having identical nucleotide residue matches and an identical 
percent sequence identity when compared to the corresponding alignment generated 
by GAP Version 10. The invention also encompasses variant nucleic acid molecules. 
"Variants" of the pesticidal protein encoding nucleotide sequences include those 
sequences that encode the pesticidal proteins disclosed herein but that differ 
conservatively because of the degeneracy of the genetic code as well as those that are 
sufficiently identical as discussed above. Naturally occurring allelic variants can be 
identified with the use of well-known molecular biology techniques, such as 
polymerase chain reaction (PCR) and hybridization techniques as outlined below. 
Variant nucleotide sequences also include synthetically derived nucleotide sequences 
that have been generated, for example, by using site-directed mutagenesis but which 
still encode the pesticidal proteins disclosed in the present invention as discussed 
below. Variant proteins encompassed by the present invention are biologically active, 
that is they continue to possess the desired biological activity of the native protein, 
that is, retaining pesticidal activity. In various embodiments, the activity is improved 
relative to Axmi205. By "retains activity" is intended that the variant will have at 
least about 30%, at least about 50%, at least about 70%, or at least about 80% of the 
pesticidal activity of the native protein. Methods for measuring pesticidal activity are 
well known in the art. See, for example, Czapla and Lang (1990) J. Econ. Entomol 
J. of Economic Entomology 78:290-293; and U.S. Patent No. 5,743,477, all of which 
are herein incorporated by reference in their entirety.
The skilled artisan will further appreciate that changes can be introduced by mutation of the nucleotide sequences of the invention thereby leading to changes in the amino acid sequence of the encoded pesticidal proteins, without altering the biological activity of the proteins. Thus, variant isolated nucleic acid molecules can be created by introducing one or more nucleotide substitutions, additions, or deletions into the corresponding nucleotide sequence disclosed herein, such that one or more amino acid substitutions, additions or deletions are introduced into the encoded protein. Mutations can be introduced by standard techniques, such as site-directed mutagenesis and PCR-mediated mutagenesis. Such variant nucleotide sequences are also encompassed by the present invention.

For example, conservative amino acid substitutions may be made at one or more, predicted, nonessential amino acid residues. A "nonessential" amino acid residue is a residue that can be altered from the wild-type sequence of a pesticidal protein without altering the biological activity, whereas an "essential" amino acid residue is required for biological activity. A "conservative amino acid substitution" is one in which the amino acid residue is replaced with an amino acid residue having a similar side chain. Families of amino acid residues having similar side chains have been defined in the art. These families include amino acids with basic side chains (e.g., lysine, arginine, histidine), acidic side chains (e.g., aspartic acid, glutamic acid), uncharged polar side chains (e.g., glycine, asparagine, glutamine, serine, threonine, tyrosine, cysteine), nonpolar side chains (e.g., alanine, valine, leucine, isoleucine, proline, phenylalanine, methionine, tryptophan), beta-branched side chains (e.g., threonine, valine, isoleucine) and aromatic side chains (e.g., tyrosine, phenylalanine, tryptophan, histidine).

Amino acid substitutions may be made in nonconserved regions that retain function. In general, such substitutions would not be made for conserved amino acid residues, or for amino acid residues residing within a conserved motif, where such residues are essential for protein activity. Examples of residues that are conserved and that may be essential for protein activity include, for example, residues that are identical between all proteins contained in an alignment of similar or related toxins to the sequences of the invention (e.g., residues that are identical in an alignment of homologous proteins). Examples of residues that are conserved but that may allow conservative amino acid substitutions and still retain activity include, for example, residues that have only conservative substitutions between all proteins contained in an
alignment of similar or related toxins to the sequences of the invention (e.g., residues that have only conservative substitutions between all proteins contained in the alignment homologous proteins). However, one of skill in the art would understand that functional variants may have minor conserved or nonconserved alterations in the conserved residues.

Alternatively, variant nucleotide sequences can be made by introducing mutations randomly along all or part of the coding sequence, such as by saturation mutagenesis, and the resultant mutants can be screened for ability to confer pesticidal activity to identify mutants that retain activity. Following mutagenesis, the encoded protein can be expressed recombinantly, and the activity of the protein can be determined using standard assay techniques.

In a hybridization method, all or part of the pesticidal nucleotide sequence can be used to screen cDNA or genomic libraries. Methods for construction of such cDNA and genomic libraries are generally known in the art and are disclosed in Sambrook and Russell, 2001, *supra*. The so-called hybridization probes may be genomic DNA fragments, cDNA fragments, RNA fragments, or other oligonucleotides, and may be labeled with a detectable group such as $^{32}$P, or any other detectable marker, such as other radioisotopes, a fluorescent compound, an enzyme, or an enzyme co-factor. Probes for hybridization can be made by labeling synthetic oligonucleotides based on the known pesticidal protein-encoding nucleotide sequence disclosed herein. Degenerate primers designed on the basis of conserved nucleotides or amino acid residues in the nucleotide sequence or encoded amino acid sequence can additionally be used. The probe typically comprises a region of nucleotide sequence that hybridizes under stringent conditions to at least about 12, at least about 25, at least about 50, 75, 100, 125, 150, 175, or 200 consecutive nucleotides of nucleotide sequence encoding a pesticidal protein of the invention or a fragment or variant thereof. Methods for the preparation of probes for hybridization are generally
known in the art and are disclosed in Sambrook and Russell, 2001, supra herein incorporated by reference.

For example, an entire pesticidal protein sequence disclosed herein, or one or more portions thereof, may be used as a probe capable of specifically hybridizing to corresponding pesticidal protein-like sequences and messenger RNAs. To achieve specific hybridization under a variety of conditions, such probes include sequences that are unique and are preferably at least about 10 nucleotides in length, or at least about 20 nucleotides in length. Such probes may be used to amplify corresponding pesticidal sequences from a chosen organism by PCR. This technique may be used to isolate additional coding sequences from a desired organism or as a diagnostic assay to determine the presence of coding sequences in an organism. Hybridization techniques include hybridization screening of plated DNA libraries (either plaques or colonies; see, for example, Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual (2d ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York).

Hybridization of such sequences may be carried out under stringent conditions. By "stringent conditions" or "stringent hybridization conditions" is intended conditions under which a probe will hybridize to its target sequence to a detectably greater degree than to other sequences (e.g., at least 2-fold over background). Stringent conditions are sequence-dependent and will be different in different circumstances. By controlling the stringency of the hybridization and/or washing conditions, target sequences that are 100% complementary to the probe can be identified (homologous probing). Alternatively, stringency conditions can be adjusted to allow some mismatching in sequences so that lower degrees of similarity are detected (heterologous probing). Generally, a probe is less than about 1000 nucleotides in length, preferably less than 500 nucleotides in length.

Typically, stringent conditions will be those in which the salt concentration is less than about 1.5 M Na ion, typically about 0.01 to 1.0 M Na ion concentration (or other salts) at pH 7.0 to 8.3 and the temperature is at least about 30°C for short probes (e.g., 10 to 50 nucleotides) and at least about 60°C for long probes (e.g., greater than 50 nucleotides). Stringent conditions may also be achieved with the addition of destabilizing agents such as formamide. Exemplary low stringency conditions include hybridization with a buffer solution of 30 to 35% formamide, 1 M NaCl, 1% SDS (sodium dodecyl sulphate) at 37°C, and a wash in 1X to 2X SSC (20X SSC = 3.0
M NaCl/0.3 M trisodium citrate) at 50 to 55°C. Exemplary moderate stringency conditions include hybridization in 40 to 45% formamide, 1.0 M NaCl, 1% SDS at 37°C, and a wash in 0.5X to 1X SSC at 55 to 60°C. Exemplary high stringency conditions include hybridization in 50% formamide, 1 M NaCl, 1% SDS at 37°C, and a wash in 0.1X SSC at 60 to 65°C. Optionally, wash buffers may comprise about 0.1% to about 1% SDS. Duration of hybridization is generally less than about 24 hours, usually about 4 to about 12 hours.

Specificity is typically the function of post-hybridization washes, the critical factors being the ionic strength and temperature of the final wash solution. For DNA-DNA hybrids, the \( T_m \) can be approximated from the equation of Meinkoth and Wahl (1984) *Anal. Biochem.* 138:267-284:

\[
T_m = 81.5^\circ C + 16.6 \log M + 0.41 \%GC - 0.61 \% form - 500/L;
\]

where \( M \) is the molarity of monovalent cations, \%GC is the percentage of guanosine and cytosine nucleotides in the DNA, \% form is the percentage of formamide in the hybridization solution, and \( L \) is the length of the hybrid in base pairs. The \( T_m \) is the temperature (under defined ionic strength and pH) at which 50% of a complementary target sequence hybridizes to a perfectly matched probe. \( T_m \) is reduced by about 1°C for each 1% of mismatching; thus, \( T_m \), hybridization, and/or wash conditions can be adjusted to hybridize to sequences of the desired identity. For example, if sequences with \( \geq 90\% \) identity are sought, the \( T_m \) can be decreased 10°C. Generally, stringent conditions are selected to be about 5°C lower than the thermal melting point (\( T_m \)) for the specific sequence and its complement at a defined ionic strength and pH. However, severely stringent conditions can utilize a hybridization and/or wash at 1, 2, 3, or 4°C lower than the thermal melting point (\( T_m \)); moderately stringent conditions can utilize a hybridization and/or wash at 6, 7, 8, 9, or 10°C lower than the thermal melting point (\( T_m \)); low stringency conditions can utilize a hybridization and/or wash at 11, 12, 13, 14, 15, or 20°C lower than the thermal melting point (\( T_m \)). Using the equation, hybridization and wash compositions, and desired \( T_m \), those of ordinary skill will understand that variations in the stringency of hybridization and/or wash solutions are inherently described. If the desired degree of mismatching results in a \( T_m \) of less than 45°C (aqueous solution) or 32°C (formamide solution), it is preferred to increase the SSC concentration so that a higher temperature can be used. An extensive guide to the hybridization of nucleic acids is found in Tijssen (1993) *Laboratory Techniques in Biochemistry and Molecular Biology—Hybridization with Nucleic Acid Probes*, Part I, Chapter 2 (Elsevier, New York); and
Isolated Proteins and Variants and Fragments Thereof

Pesticidal proteins are also encompassed within the present invention. By "pesticidal protein" is intended a protein having the amino acid sequence set forth in SEQ ID NO:7, 8, 9, 10, 11, or 12. Fragments, biologically active portions, and variants thereof (e.g., SEQ ID NO:5, 6, 7, and 8) are also provided, and may be used to practice the methods of the present invention. An "isolated protein" is used to refer to a protein that is no longer in its natural environment, for example in vitro or in a recombinant bacterial or plant host cell.

"Fragments" or "biologically active portions" include polypeptide fragments comprising amino acid sequences sufficiently identical to the amino acid sequence set forth in SEQ ID NO:7, 8, 9, 10, 11, or 12, and that exhibit pesticidal activity. A biologically active portion of a pesticidal protein can be a polypeptide that is, for example, 10, 25, 50, 100, 150, 200, 250 or more amino acids in length. Such biologically active portions can be prepared by recombinant techniques and evaluated for pesticidal activity. Methods for measuring pesticidal activity are well known in the art. See, for example, Czapla and Lang (1990) J. Econ. Entomol. 83:2480-2485; Andrews et al. (1988) Biochem. J. 252:199-206; Marrone et al. (1985) J. of Economic Entomology 78:290-293; and U.S. Patent No. 5,743,477, all of which are herein incorporated by reference in their entirety. As used here, a fragment comprises at least 8 contiguous amino acids of SEQ ID NO:7, 8, 9, 10, 11, or 12. The invention encompasses other fragments, however, such as any fragment in the protein greater than about 10, 20, 30, 50, 100, 150, 200, 250, 300, 350, 400, 450, 500, 550 or more amino acids.

In some embodiments, the fragment is an N-terminal or a C-terminal truncation of at least about 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 25 or more amino acids relative to SEQ ID NO:7, 8, 9, 10, 11, or 12. In some embodiments, the fragments encompassed herein result from the removal of the C-terminal 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 25 or more
amino acids, e.g., by proteolysis or by insertion of a stop codon in the coding sequence.

By "variants" is intended proteins or polypeptides having an amino acid sequence that is at least about 60%, 65%, about 70%, 75%, about 80%, 85%, about 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98% or 99% identical to the amino acid sequence of SEQ ID NO:7, 8, 9, 10, 11, or 12, or an amino acid sequence that has 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, or more amino acid additions, deletions, or substitutions relative to the amino acid sequence of SEQ ID NO:2. Variants also include polypeptides encoded by a nucleic acid molecule that hybridizes to the nucleic acid molecule of SEQ ID NO:4, 5, or 6, or a complement thereof, under stringent conditions. Variants include polypeptides that differ in amino acid sequence due to mutagenesis. Variant proteins encompassed by the present invention are biologically active, that is they continue to possess the desired biological activity of the native protein, that is, retaining pesticidal activity. In some embodiments, the variants have improved activity relative to the native protein (e.g., relative to Axmi205). By "retains activity" is intended that the fragment will have at least about 30%, at least about 50%, at least about 70%, 80%, 90%, 95% or higher of the pesticidal activity of the pesticidal protein. By "improved activity" is intended an increase of at least about 10%, at least about 15%, at least about 20%, at least about 25%, at least about 30%, at least about 35%, at least about 40%, at least about 50%, 60%, 70%, 80%, 90%, or higher, or at least about 1.5-fold, at least about 2-fold, at least about 2.5-fold, at least about 3-fold or higher increase in the pesticidal activity of the variant protein relative to the pesticidal activity of Axmi205. In some embodiments, the improvement consists of a decrease in the LC50 relative to the LC50 of Axmi205, e.g., a decrease of at least about 10%, at least about 20%, at least about 30%, at least about 40%, at least about 50%, at least about 55%, at least about 60%, or greater reduction in the LC50. Methods for measuring pesticidal activity are well known in the art. See, for example, Czapla and Lang (1990) J. Econ. Entomol. 83:2480-2485; Andrews et al. (1988) Biochem. J. 252:199-206; Marrone et al. (1985) J. of Economic Entomology 78:290-293; and U.S. Patent No. 5,743,477, all of which are herein incorporated by reference in their entirety.

Bacterial genes, such as the axmi genes of this invention, quite often possess multiple methionine initiation codons in proximity to the start of the open reading frame. Often, translation initiation at one or more of these start codons will lead to
generation of a functional protein. These start codons can include ATG codons. However, bacteria such as *Bacillus sp.* also recognize the codon GTG as a start codon, and proteins that initiate translation at GTG codons contain a methionine at the first amino acid. On rare occasions, translation in bacterial systems can initiate at a TTG codon, though in this event the TTG encodes a methionine. Furthermore, it is not often determined *a priori* which of these codons are used naturally in the bacterium. Thus, it is understood that use of one of the alternate methionine codons may also lead to generation of pesticidal proteins, these pesticidal proteins are encompassed in the present invention and may be used in the methods of the present invention. It will be understood that, when expressed in plants, it will be necessary to alter the alternate start codon to ATG for proper translation.

Antibodies to the polypeptides of the present invention, or to variants or fragments thereof, are also encompassed. Methods for producing antibodies are well known in the art (see, for example, Harlow and Lane (1988) *Antibodies: A Laboratory Manual*, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY; U.S. Patent No. 4,196,265).

Thus, one aspect of the invention concerns antibodies, single-chain antigen binding molecules, or other proteins that specifically bind to one or more of the protein or peptide molecules of the invention and their homologs, fusions or fragments. In a particularly preferred embodiment, the antibody specifically binds to a protein having the amino acid sequence set forth in SEQ ID NO: 7, 8, 9, 10, 11, or 12 or a fragment thereof. In another embodiment, the antibody specifically binds to a fusion protein comprising an amino acid sequence selected from the amino acid sequence set forth in SEQ ID NO: 7, 8, 9, 10, 11, or 12 or a fragment thereof.

Antibodies of the invention may be used to quantitatively or qualitatively detect the protein or peptide molecules of the invention, or to detect post translational modifications of the proteins. As used herein, an antibody or peptide is said to "specifically bind" to a protein or peptide molecule of the invention if such binding is not competitively inhibited by the presence of non-related molecules.

**Altered or Improved Variants**

It is recognized that DNA sequences of a pesticidal protein may be further altered by various methods, and that these alterations may result in DNA sequences encoding proteins with amino acid sequences different than that encoded by a
pesticidal protein of the present invention. This protein may be altered in various ways including amino acid substitutions, deletions, truncations, and insertions of one or more amino acids of SEQ ID NO:2, including up to about 2, about 3, about 4, about 5, about 6, about 7, about 8, about 9, about 10, about 15, about 20, about 25, about 30, about 35, about 40, about 45, about 50, about 55, about 60, about 65, about 70, about 75, about 80, about 85, about 90, about 100, about 105, about 110, about 115, about 120, about 125, about 130, about 135, about 140, about 145, about 150, about 155, or more amino acid substitutions, deletions or insertions. In some embodiments, the substitutions occur in one or more of amino acid positions 464, 465, 466, or 467 relative to the amino acid sequence of SEQ ID NO:2. In some embodiments, the variant amino acid sequence is set forth in SEQ ID NO:7, 8, 9, 10, 11, or 12. One of skill in the art will recognize that additional amino acid additions, substitutions, or deletions to SEQ ID NO:7, 8, 9, 10, 11, or 12 can be made as described herein.

Methods for such manipulations are generally known in the art. For example, amino acid sequence variants of a pesticidal protein can be prepared by mutations in the DNA. This may also be accomplished by one of several forms of mutagenesis and/or in directed evolution. In some aspects, the changes encoded in the amino acid sequence will not substantially affect the function of the protein. Such variants will possess the desired pesticidal activity. However, it is understood that the ability of a pesticidal protein to confer pesticidal activity may be improved by the use of such techniques upon the compositions of this invention. For example, one may express a pesticidal protein in host cells that exhibit high rates of base misincorporation during DNA replication, such as XL-1 Red (Stratagene, La Jolla, CA). After propagation in such strains, one can isolate the DNA (for example by preparing plasmid DNA, or by amplifying by PCR and cloning the resulting PCR fragment into a vector), culture the pesticidal protein mutations in a non-mutagenic strain, and identify mutated genes with pesticidal activity, for example by performing an assay to test for pesticidal activity. Generally, the protein is mixed and used in feeding assays. See, for example Marrone et al. (1985) J. of Economic Entomology 78:290-293. Such assays can include contacting plants with one or more pests and determining the plant's ability to survive and/or cause the death of the pests.

Alternatively, alterations may be made to the protein sequence of many proteins at the amino or carboxy terminus without substantially affecting activity.
This can include insertions, deletions, or alterations introduced by modern molecular methods, such as PCR, including PCR amplifications that alter or extend the protein coding sequence by virtue of inclusion of amino acid encoding sequences in the oligonucleotides utilized in the PCR amplification. Alternatively, the protein sequences added can include entire protein-coding sequences, such as those used commonly in the art to generate protein fusions. Such fusion proteins are often used to (1) increase expression of a protein of interest (2) introduce a binding domain, enzymatic activity, or epitope to facilitate either protein purification, protein detection, or other experimental uses known in the art (3) target secretion or translation of a protein to a subcellular organelle, such as the periplasmic space of Gram-negative bacteria, or the endoplasmic reticulum of eukaryotic cells, the latter of which often results in glycosylation of the protein.

Variant nucleotide and amino acid sequences of the present invention also encompass sequences derived from mutagenic and recombinogenic procedures such as DNA shuffling. With such a procedure, one or more different pesticidal protein coding regions can be used to create a new pesticidal protein possessing the desired properties. In this manner, libraries of recombinant polynucleotides are generated from a population of related sequence polynucleotides comprising sequence regions that have substantial sequence identity and can be homologously recombined in vitro or in vivo. For example, using this approach, sequence motifs encoding a domain of interest may be shuffled between a pesticidal gene of the invention and other known pesticidal genes to obtain a new gene coding for a protein with an improved property of interest, such as an increased insecticidal activity. Strategies for such DNA shuffling are known in the art. See, for example, Stemmer (1994) *Proc. Natl. Acad. Sci. USA* 91:10747-10751; Stemmer (1994) *Nature* 370:389-391; Crameri *et al.* (1997) *Nature Biotech.* 15:436-438; Moore *et al.* (1997) *J. Mol. Biol.* 272:336-347; Zhang *et al.* (1997) *Proc. Natl. Acad. Sci. USA* 94:4504-4509; Crameri *et al.* (1998) *Nature* 391:288-291; and U.S. Patent Nos. 5,605,793 and 5,837,458.

Domain swapping or shuffling is another mechanism for generating altered pesticidal proteins. Domains may be swapped between pesticidal proteins, resulting in hybrid or chimeric toxins with improved pesticidal activity or target spectrum. Methods for generating recombinant proteins and testing them for pesticidal activity are well known in the art (see, for example, Naimov *et al.* (2001) *Appl. Environ. Microbiol.* 67:5328-5330; de Maagd *et al.* (1996) *Appl. Environ. Microbiol.* 62:1537-

Vectors

A pesticidal sequence of the invention may be provided in an expression cassette for expression in a plant of interest. By "plant expression cassette" is intended a DNA construct that is capable of resulting in the expression of a protein from an open reading frame in a plant cell. Typically these contain a promoter and a coding sequence. Often, such constructs will also contain a 3’ untranslated region. Such constructs may contain a "signal sequence" or "leader sequence" to facilitate cotranslational or post-translational transport of the peptide to certain intracellular structures such as the chloroplast (or other plastid), endoplasmic reticulum, or Golgi apparatus.

By "signal sequence" is intended a sequence that is known or suspected to result in cotranslational or post-translational peptide transport across the cell membrane. In eukaryotes, this typically involves secretion into the Golgi apparatus, with some resulting glycosylation. Insecticidal toxins of bacteria are often synthesized as protoxins, which are protolytically activated in the gut of the target pest (Chang (1987) Methods Enzymol. 153:507-516). In some embodiments of the present invention, the signal sequence is located in the native sequence, or may be derived from a sequence of the invention. By "leader sequence" is intended any sequence that when translated, results in an amino acid sequence sufficient to trigger cotranslational transport of the peptide chain to a subcellular organelle. Thus, this includes leader sequences targeting transport and/or glycosylation by passage into the endoplasmic reticulum, passage to vacuoles, plastids including chloroplasts, mitochondria, and the like.

By "plant transformation vector" is intended a DNA molecule that is necessary for efficient transformation of a plant cell. Such a molecule may consist of one or more plant expression cassettes, and may be organized into more than one "vector" DNA molecule. For example, binary vectors are plant transformation vectors that utilize two non-contiguous DNA vectors to encode all requisite cis- and trans-acting functions for transformation of plant cells (Hellens and Mullineaux (2000) Trends in Plant Science 5:446-451). "Vector" refers to a nucleic acid
construct designed for transfer between different host cells. "Expression vector" refers to a vector that has the ability to incorporate, integrate and express heterologous DNA sequences or fragments in a foreign cell. The cassette will include 5' and 3' regulatory sequences operably linked to a sequence of the invention. By "operably linked" is intended a functional linkage between a promoter and a second sequence, wherein the promoter sequence initiates and mediates transcription of the DNA sequence corresponding to the second sequence. Generally, operably linked means that the nucleic acid sequences being linked are contiguous and, where necessary to join two protein coding regions, contiguous and in the same reading frame. The cassette may additionally contain at least one additional gene to be cotransformed into the organism. Alternatively, the additional gene(s) can be provided on multiple expression cassettes.

"Promoter" refers to a nucleic acid sequence that functions to direct transcription of a downstream coding sequence. The promoter together with other transcriptional and translational regulatory nucleic acid sequences (also termed "control sequences") are necessary for the expression of a DNA sequence of interest. Such an expression cassette is provided with a plurality of restriction sites for insertion of the pesticidal sequence to be under the transcriptional regulation of the regulatory regions.

The expression cassette will include in the 5'-3' direction of transcription, a transcriptional and translational initiation region (i.e., a promoter), a DNA sequence of the invention, and a translational and transcriptional termination region (i.e., termination region) functional in plants. The promoter may be native or analogous, or foreign or heterologous, to the plant host and/or to the DNA sequence of the invention. Additionally, the promoter may be the natural sequence or alternatively a synthetic sequence. Where the promoter is "native" or "homologous" to the plant host, it is intended that the promoter is found in the native plant into which the promoter is introduced. Where the promoter is "foreign" or "heterologous" to the DNA sequence of the invention, it is intended that the promoter is not the native or naturally occurring promoter for the operably linked DNA sequence of the invention.

The termination region may be native with the transcriptional initiation region, may be native with the operably linked DNA sequence of interest, may be native with the plant host, or may be derived from another source (i.e., foreign or heterologous to the promoter, the DNA sequence of interest, the plant host, or any combination

Where appropriate, the gene(s) may be optimized for increased expression in the transformed host cell. That is, the genes can be synthesized using host cell-preferred codons for improved expression, or may be synthesized using codons at a host-preferred codon usage frequency. Generally, the GC content of the gene will be increased. See, for example, Campbell and Gowri (1990) *Plant Physiol.* 92:1-11 for a discussion of host-preferred codon usage. Methods are available in the art for synthesizing plant-preferred genes. See, for example, U.S. Patent Nos. 5,380,831 and 5,436,391, and Murray *et al.* (1989) *Nucleic Acids Res.* 17:477-498, herein incorporated by reference.

The pesticidal gene to be targeted to the chloroplast may be optimized for expression in the chloroplast to account for differences in codon usage between the plant nucleus and this organelle. In this manner, the nucleic acids of interest may be synthesized using chloroplast-preferred codons. See, for example, U.S. Patent No. 5,380,831, herein incorporated by reference.

**Plant Transformation**

Methods of the invention involve introducing a nucleotide construct into a plant. By "introducing" is intended to present to the plant the nucleotide construct in such a manner that the construct gains access to the interior of a cell of the plant. The
methods of the invention do not require that a particular method for introducing a nucleotide construct to a plant is used, only that the nucleotide construct gains access to the interior of at least one cell of the plant. Methods for introducing nucleotide constructs into plants are known in the art including, but not limited to, stable transformation methods, transient transformation methods, and virus-mediated methods.

By "plant" is intended whole plants, plant organs (e.g., leaves, stems, roots, etc.), seeds, plant cells, propagules, embryos and progeny of the same. Plant cells can be differentiated or undifferentiated (e.g. callus, suspension culture cells, protoplasts, leaf cells, root cells, phloem cells, pollen).

"Transgenic plants" or "transformed plants" or "stably transformed" plants or cells or tissues refers to plants that have incorporated or integrated exogenous nucleic acid sequences or DNA fragments into the plant cell. These nucleic acid sequences include those that are exogenous, or not present in the untransformed plant cell, as well as those that may be endogenous, or present in the untransformed plant cell. "Heterologous" generally refers to the nucleic acid sequences that are not endogenous to the cell or part of the native genome in which they are present, and have been added to the cell by infection, transfection, microinjection, electroporation, microprojection, or the like.

The transgenic plants of the invention express one or more of the pesticidal sequences disclosed herein. In various embodiments, the transgenic plant further comprises one or more additional genes for insect resistance, for example, one or more additional genes for controlling coleopteran, lepidopteran, heteropteran, or nematode pests. It will be understood by one of skill in the art that the transgenic plant may comprise any gene imparting an agronomic trait of interest.

Transformation of plant cells can be accomplished by one of several techniques known in the art. The pesticidal gene of the invention may be modified to obtain or enhance expression in plant cells. Typically a construct that expresses such a protein would contain a promoter to drive transcription of the gene, as well as a 3' untranslated region to allow transcription termination and polyadenylation. The organization of such constructs is well known in the art. In some instances, it may be useful to engineer the gene such that the resulting peptide is secreted, or otherwise targeted within the plant cell. For example, the gene can be engineered to contain a signal peptide to facilitate transfer of the peptide to the endoplasmic reticulum. It
may also be preferable to engineer the plant expression cassette to contain an intron, such that mRNA processing of the intron is required for expression.

Typically this "plant expression cassette" will be inserted into a "plant transformation vector". This plant transformation vector may be comprised of one or more DNA vectors needed for achieving plant transformation. For example, it is a common practice in the art to utilize plant transformation vectors that are comprised of more than one contiguous DNA segment. These vectors are often referred to in the art as "binary vectors". Binary vectors as well as vectors with helper plasmids are most often used for Agrobacterium-mQdialQd transformation, where the size and complexity of DNA segments needed to achieve efficient transformation is quite large, and it is advantageous to separate functions onto separate DNA molecules. Binary vectors typically contain a plasmid vector that contains the cis-acting sequences required for T-DNA transfer (such as left border and right border), a selectable marker that is engineered to be capable of expression in a plant cell, and a "gene of interest" (a gene engineered to be capable of expression in a plant cell for which generation of transgenic plants is desired). Also present on this plasmid vector are sequences required for bacterial replication. The cis-acting sequences are arranged in a fashion to allow efficient transfer into plant cells and expression therein. For example, the selectable marker gene and the pesticidal gene are located between the left and right borders. Often a second plasmid vector contains the trans-acting factors that mediate T-DNA transfer from Agrobacterium to plant cells. This plasmid often contains the virulence functions (Vir genes) that allow infection of plant cells by Agrobacterium, and transfer of DNA by cleavage at border sequences and vir-mediated DNA transfer, as is understood in the art (Hellens and Mullineaux (2000) Trends in Plant Science 5:446-451). Several types of Agrobacterium strains (e.g. LBA4404, GV3101, EHA101, EHA105, etc.) can be used for plant transformation. The second plasmid vector is not necessary for transforming the plants by other methods such as microprojection, microinjection, electroporation, polyethylene glycol, etc.

In general, plant transformation methods involve transferring heterologous DNA into target plant cells (e.g. immature or mature embryos, suspension cultures, undifferentiated callus, protoplasts, etc.), followed by applying a maximum threshold level of appropriate selection (depending on the selectable marker gene) to recover the transformed plant cells from a group of untransformed cell mass. Explants are
typically transferred to a fresh supply of the same medium and cultured routinely. Subsequently, the transformed cells are differentiated into shoots after placing on regeneration medium supplemented with a maximum threshold level of selecting agent. The shoots are then transferred to a selective rooting medium for recovering rooted shoot or plantlet. The transgenic plantlet then grows into a mature plant and produces fertile seeds (e.g. Hiei et al. (1994) *The Plant Journal* 6:271-282; Ishida et al. (1996) *Nature Biotechnology* 14:745-750). Explants are typically transferred to a fresh supply of the same medium and cultured routinely. A general description of the techniques and methods for generating transgenic plants are found in Ayres and Park (1994) *Critical Reviews in Plant Science* 13:2 19-239 and Bommineni and Jauhar (1997) *Maydica* 42: 107-120. Since the transformed material contains many cells; both transformed and non-transformed cells are present in any piece of subjected target callus or tissue or group of cells. The ability to kill non-transformed cells and allow transformed cells to proliferate results in transformed plant cultures. Often, the ability to remove non-transformed cells is a limitation to rapid recovery of transformed plant cells and successful generation of transgenic plants.

Transformation protocols as well as protocols for introducing nucleotide sequences into plants may vary depending on the type of plant or plant cell, i.e., monocot or dicot, targeted for transformation. Generation of transgenic plants may be performed by one of several methods, including, but not limited to, microinjection, electroporation, direct gene transfer, introduction of heterologous DNA by *Agrobacterium* into plant cells (*Agrobacterium-mQdiatQd* transformation), bombardment of plant cells with heterologous foreign DNA adhered to particles, ballistic particle acceleration, aerosol beam transformation (U.S. Published Application No. 2001026941; U.S. Patent No. 4,945,050; International Publication No. WO 91/00915; U.S. Published Application No. 200201 5066), Lec1 transformation, and various other non-particle direct-mediated methods to transfer DNA.

accomplished by transactivation of a silent plastid-borne transgene by tissue-preferred expression of a nuclear-encoded and plastid-directed RNA polymerase. Such a system has been reported in McBride et al. (1994) Proc. Natl. Acad. Set USA 91:7301-7305.

Following integration of heterologous foreign DNA into plant cells, one then applies a maximum threshold level of appropriate selection in the medium to kill the untransformed cells and separate and proliferate the putatively transformed cells that survive from this selection treatment by transferring regularly to a fresh medium. By continuous passage and challenge with appropriate selection, one identifies and proliferates the cells that are transformed with the plasmid vector. Molecular and biochemical methods can then be used to confirm the presence of the integrated heterologous gene of interest into the genome of the transgenic plant.

The cells that have been transformed may be grown into plants in accordance with conventional ways. See, for example, McCormick et al. (1986) Plant Cell Reports 5:81-84. These plants may then be grown, and either pollinated with the same transformed strain or different strains, and the resulting hybrid having constitutive expression of the desired phenotypic characteristic identified. Two or more generations may be grown to ensure that expression of the desired phenotypic characteristic is stably maintained and inherited and then seeds harvested to ensure expression of the desired phenotypic characteristic has been achieved. In this manner, the present invention provides transformed seed (also referred to as "transgenic seed") having a nucleotide construct of the invention, for example, an expression cassette of the invention, stably incorporated into their genome.

Evaluation of Plant Transformation

Following introduction of heterologous foreign DNA into plant cells, the transformation or integration of heterologous gene in the plant genome is confirmed by various methods such as analysis of nucleic acids, proteins and metabolites associated with the integrated gene.

PCR analysis is a rapid method to screen transformed cells, tissue or shoots for the presence of incorporated gene at the earlier stage before transplanting into the soil (Sambrook and Russell (2001) Molecular Cloning: A Laboratory Manual. Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY). PCR is carried out using
oligonucleotide primers specific to the gene of interest or Agrobacterium vector background, etc.

Plant transformation may be confirmed by Southern blot analysis of genomic DNA (Sambrook and Russell, 2001, supra). In general, total DNA is extracted from the transformant, digested with appropriate restriction enzymes, fractionated in an agarose gel and transferred to a nitrocellulose or nylon membrane. The membrane or "blot" is then probed with, for example, radiolabeled $^{32}$P target DNA fragment to confirm the integration of introduced gene into the plant genome according to standard techniques (Sambrook and Russell, 2001, supra).

In Northern blot analysis, RNA is isolated from specific tissues of transformant, fractionated in a formaldehyde agarose gel, and blotted onto a nylon filter according to standard procedures that are routinely used in the art (Sambrook and Russell, 2001, supra). Expression of RNA encoded by the pesticidal gene is then tested by hybridizing the filter to a radioactive probe derived from a pesticidal gene, by methods known in the art (Sambrook and Russell, 2001, supra).

Western blot, biochemical assays and the like may be carried out on the transgenic plants to confirm the presence of protein encoded by the pesticidal gene by standard procedures (Sambrook and Russell, 2001, supra) using antibodies that bind to one or more epitopes present on the pesticidal protein.

Pesticidal Activity in Plants

In another aspect of the invention, one may generate transgenic plants expressing a pesticidal protein that has pesticidal activity. Methods described above by way of example may be utilized to generate transgenic plants, but the manner in which the transgenic plant cells are generated is not critical to this invention. Methods known or described in the art such as Agrobacterium-mediated transformation, biolistic transformation, and non-particle-mediated methods may be used at the discretion of the experimenter. Plants expressing a pesticidal protein may be isolated by common methods described in the art, for example by transformation of callus, selection of transformed callus, and regeneration of fertile plants from such transgenic callus. In such process, one may use any gene as a selectable marker so long as its expression in plant cells confers ability to identify or select for transformed cells.
A number of markers have been developed for use with plant cells, such as resistance to chloramphenicol, the aminoglycoside G418, hygromycin, or the like. Other genes that encode a product involved in chloroplast metabolism may also be used as selectable markers. For example, genes that provide resistance to plant herbicides such as glyphosate, bromoxynil, or imidazolinone may find particular use. Such genes have been reported (Stalker et al. (1985) J. Biol. Chem. 263:63 10-63 14 (bromoxynil resistance nitrilase gene); and Sathasivan et al. (1990) Nucl. Acids Res. 18:2188 (AHAS imidazolinone resistance gene). Additionally, the genes disclosed herein are useful as markers to assess transformation of bacterial or plant cells.

Methods for detecting the presence of a transgene in a plant, plant organ (e.g., leaves, stems, roots, etc.), seed, plant cell, propagule, embryo or progeny of the same are well known in the art. In one embodiment, the presence of the transgene is detected by testing for pesticidal activity.

Fertile plants expressing a pesticidal protein may be tested for pesticidal activity, and the plants showing optimal activity selected for further breeding. Methods are available in the art to assay for pest activity. Generally, the protein is mixed and used in feeding assays. See, for example Marrone et al. (1985) J. of Economic Entomology 78:290-293.

The present invention may be used for transformation of any plant species, including, but not limited to, monocots and dicots. Examples of plants of interest include, but are not limited to, corn (maize), sorghum, wheat, sunflower, tomato, crucifers, peppers, potato, cotton, rice, soybean, sugarbeet, sugarcane, tobacco, barley, and oilseed rape, Brassica sp., alfalfa, rye, millet, safflower, peanuts, sweet potato, cassava, coffee, coconut, pineapple, citrus trees, cocoa, tea, banana, avocado, fig, guava, mango, olive, papaya, cashew, macadamia, almond, oats, vegetables, ornamentals, and conifers.

Vegetables include, but are not limited to, tomatoes, lettuce, green beans, lima beans, peas, and members of the genus Curcumin such as cucumber, cantaloupe, and musk melon. Ornamentals include, but are not limited to, azalea, hydrangea, hibiscus, roses, tulips, daffodils, petunias, carnation, poinsettia, and chrysanthemum. Preferably, plants of the present invention are crop plants (for example, maize, sorghum, wheat, sunflower, tomato, crucifers, peppers, potato, cotton, rice, soybean, sugarbeet, sugarcane, tobacco, barley, oilseed rape., etc.).
Use in Pesticidal Control

General methods for employing strains comprising a nucleotide sequence of the present invention, or a variant thereof, in pesticide control or in engineering other organisms as pesticidal agents are known in the art. See, for example U.S. Patent No. 5,039,523 and EP 0480762A2.

The Bacillus strains containing a nucleotide sequence of the present invention, or a variant thereof, or the microorganisms that have been genetically altered to contain a pesticidal gene and protein may be used for protecting agricultural crops and products from pests. In one aspect of the invention, whole, i.e., unlysed, cells of a toxin (pesticide)-producing organism are treated with reagents that prolong the activity of the toxin produced in the cell when the cell is applied to the environment of target pest(s).

Alternatively, the pesticide is produced by introducing a pesticidal gene into a cellular host. Expression of the pesticidal gene results, directly or indirectly, in the intracellular production and maintenance of the pesticide. In one aspect of this invention, these cells are then treated under conditions that prolong the activity of the toxin produced in the cell when the cell is applied to the environment of target pest(s). The resulting product retains the toxicity of the toxin. These naturally encapsulated pesticides may then be formulated in accordance with conventional techniques for application to the environment hosting a target pest, e.g., soil, water, and foliage of plants. See, for example EPA 0192319, and the references cited therein. Alternatively, one may formulate the cells expressing a gene of this invention such as to allow application of the resulting material as a pesticide.

Pesticidal compositions

The active ingredients of the present invention are normally applied in the form of compositions and can be applied to the crop area or plant to be treated, simultaneously or in succession, with other compounds. These compounds can be fertilizers, weed killers, cryoprotectants, surfactants, detergents, pesticidal soaps, dormant oils, polymers, and/or time-release or biodegradable carrier formulations that permit long-term dosing of a target area following a single application of the formulation. They can also be selective herbicides, chemical insecticides, virucides, microbicides, amoebicides, pesticides, fungicides, bacteriocides, nematocides, molluscsicides or mixtures of several of these preparations, if desired, together with
further agriculturally acceptable carriers, surfactants or application-promoting
adjuvants customarily employed in the art of formulation. Suitable carriers and
adjuvants can be solid or liquid and correspond to the substances ordinarily employed
in formulation technology, e.g. natural or regenerated mineral substances, solvents,
dispersants, wetting agents, tackifiers, binders or fertilizers. Likewise the formulations
may be prepared into edible "baits" or fashioned into pest "traps" to permit feeding or
ingestion by a target pest of the pesticidal formulation.

Methods of applying an active ingredient of the present invention or an
agrochemical composition of the present invention that contains at least one of the
pesticidal proteins produced by the bacterial strains of the present invention include
leaf application, seed coating and soil application. The number of applications and
the rate of application depend on the intensity of infestation by the corresponding
pest.

The composition may be formulated as a powder, dust, pellet, granule, spray,
emulsion, colloid, solution, or such like, and may be prepared by such conventional
means as desiccation, lyophilization, homogenation, extraction, filtration,
centrifugation, sedimentation, or concentration of a culture of cells comprising the
polypeptide. In all such compositions that contain at least one such pesticidal
polypeptide, the polypeptide may be present in a concentration of from about 1% to
about 99% by weight.

Lepidopteran, dipteran, heteropteran, nematode, or coleopteran pests may be
killed or reduced in numbers in a given area by the methods of the invention, or may
be prophylactically applied to an environmental area to prevent infestation by a
susceptible pest. Preferably the pest ingests, or is contacted with, a pesticidally-
effective amount of the polypeptide. By "pesticidally-effective amount" is intended
an amount of the pesticide that is able to bring about death to at least one pest, or to
noticeably reduce pest growth, feeding, or normal physiological development. This
amount will vary depending on such factors as, for example, the specific target pests
to be controlled, the specific environment, location, plant, crop, or agricultural site to
be treated, the environmental conditions, and the method, rate, concentration,
stability, and quantity of application of the pesticidally-effective polypeptide
composition. The formulations may also vary with respect to climatic conditions,
environmental considerations, and/or frequency of application and/or severity of pest
infestation.
The pesticide compositions described may be made by formulating either the bacterial cell, crystal and/or spore suspension, or isolated protein component with the desired agriculturally-acceptable carrier. The compositions may be formulated prior to administration in an appropriate means such as lyophilized, freeze-dried, desiccated, or in an aqueous carrier, medium or suitable diluent, such as saline or other buffer. The formulated compositions may be in the form of a dust or granular material, or a suspension in oil (vegetable or mineral), or water or oil/water emulsions, or as a wettable powder, or in combination with any other carrier material suitable for agricultural application. Suitable agricultural carriers can be solid or liquid and are well known in the art. The term "agriculturally-acceptable carrier" covers all adjuvants, inert components, dispersants, surfactants, tackifiers, binders, etc. that are ordinarily used in pesticide formulation technology; these are well known to those skilled in pesticide formulation. The formulations may be mixed with one or more solid or liquid adjuvants and prepared by various means, e.g., by homogeneous mixing, blending and/or grinding the pesticidal composition with suitable adjuvants using conventional formulation techniques. Suitable formulations and application methods are described in U.S. Patent No. 6,468,523, herein incorporated by reference.

The plants can also be treated with one or more chemical compositions, including one or more herbicide, insecticides, or fungicides. Exemplary chemical compositions include: Fruits/Vegetables Herbicides: Atrazine, Bromacil, Diuron, Glyphosate, Linuron, Metribuzin, Simazine, Trifluralin, Fluazifop, Glufosinate, Halosulfuron Gowan, Paraquat, Propyzamide, Sethoxydim, Butafenacil, Halosulfuron, Indaziflam; Fruits/Vegetables Insecticides: Aldicarb, Bacillus thuriengiensis, Carbaryl, Carbofuran, Chlorpyrifos, Cypermethrin, Deltamethrin, Diazinon, Malathion, Abamectin, Cyfluthrin/beta-cyfluthrin, Esfenvalerate, Lambda-cyhalothrin, Acequinocyl, Bifenazate, Methoxyfenozide, Novaluron, Chromafenozide, Thiacloprid, Dinotefuran, Fluacrypyrim, Tolfenpyrad, Clothianidin, Spirodiclofen, Gamma-cyhalothrin, Spiromesifen, Spinosad, Rynaxypyr, Cyazypyr, Spinetoram, Triflumuron, Sprirotetramat, Imidacloprid, Flubendiamide, Thiodicarb, Metaflumizone, Sufloxaflor, Cyflumetofen, Cyanopyrafen, Imidacloprid, Clothianidin, Thiamethoxam, Spinotoram, Thiodicarb, Flonicamid, Methiocarb, Emamectin-benzoate, Indoxacarb, Fozthiazate, Fenamiphos, Cadusaphos,
Pyriproxifen, Fenbutatin-oxid, Hexthiazox, Methomyl, 4-[[6-Chlorpyridin-3-yl]methyl][2,2-difluoroethyl]amino]furan-2(5H)-on; Fruits/Vegetables Fungicides:
Penoxsulam, Bispyribac, Oxadiargyl, Ethoxysulfuron, Pretilachlor, Mesotrione, Tefuryltrione, Oxadiazone, Fenoxaprop, Pyrimisulfan; **Rice Insecticides:** Diazinon, Fenitrothion, Fenobucarb, Monocrotophos, Benfuracarb, Buprofezin, Dinofuran, Fipronil, Imidacloprid, Isoprotocarb, Thiacloprid, Chromafenozide, Thiacloprid,

Dinofuran, Clothianidin, Ethoprop, Flubendiamide, Rynaxypyr, Deltamethrin, Acetamiprid, Thiamethoxam, Cyazypyr, Spinosad, Spinotram, Emamectin-Benzoate, Cypermethrin, Chlorpyrifos, Cartap, Methamidophos, Etofenprox, Triazophos, 4-[[6-Chlorpyridin-3-yl)methyl][2,2-difluorethyl]amino]furan-2(5H)-on, Carbofuran, Benfuracarb; **Rice Fungicides:** Thiophanate-methyl, Azoxystrinobin, Carpropanid, Edifenphos, Ferimzone, Iprobenfos, Isoprothiolane, Pencycuron, Probenazole, Pyroquilon, Tricyclazole, Triflueistrobin, Diclocymet, Fenoxanil, Simeconazole, Tiadiniil; **Cotton Herbicides:** Diuron, Fluometuron, MSMA, Oxyfluorfen, Prometryn, Trifuralin, Carfentrazione, Clethodiol, Fluazifop-butil, Glyphosate, Norflurazon, Pendimethalin, Pyrithiobac-sodium, Triflusulfuron,

Tepraloxydim, Glufosinate, Flumioxazin, Thidiazuron; **Cotton Insecticides:** Acephate, Aldicarb, Chlorpyrifos, Cypermethrin, Deltamethrin, Malathion, Monocrotophos, Abamectin, Acetamiprid, Emamectin Benzoate, Imidacloprid, Indoxacarb, Lambda-Cyhalothrin, Spinosod, Thiodicarb, Gamma-Cyhalothrin, Spiromesifen, Pyridalyl, Flonicamid, Flubendiamide, Triflumuron, Rynaxypyr, Beta-Cyfluthrin, Spirotetramat,

Clothianidin, Thiamethoxam, Thiacloprid, Dinofuran, Flubendiamide, Cyazypyr, Spinosad, Spinotram, gamma Cyhalothrin, 4-[[6-Chlorpyridin-3-yl)methyl][2,2-difluorethyl]amino]furan-2(5H)-on, Thiodicarb, Avermectin, Flonicamid, Pyridalyl, Spiromesifen, Sulfoxaflor, Profenphos, Thiazophos, Endosulfan; **Cotton Fungicides:** Etridiazole, Metalaxyl, Quinozene; **Soybean Herbicides:** Alachlor, Bentazon, Trifluralin, Chlorimuron-Ethyl, Cloransulam-Methyl, Fenoxaprop, Fomesafen, Fluazipof, Glyphosate, Imazamox, Imazaquin, Imazethapyr, (S-)Metolachlor, Methobenzin, Pendimethalin, Tepraloxydim, Glufosinate; **Soybean Insecticides:** Lambda-cyhalothrin. Methomyl, Parathion, Thiocarb, Imidacloprid, Clothianidin, Thiamethoxam, Thiacloprid, Acetamiprid, Dinofuran, Flubendiamide,

Rynaxypyr, Cyazypyr, Spinosad, Spinotram, Emamectin-Benzoate, Fipronil, Ethoprop, Deltamethrin, β-Cyfluthrin, gamma and lambda Cyhalothrin, 4-[[6-Chlorpyridin-3-yl)methyl][2,2-difluorethyl]amino]furan-2(5H)-on, Spirotetramat, Spinodiclofen, Triflumuron, Flonicamid, Thiodicarb, beta-Cyfluthrin; **Soybean Fungicides:** Azoxystrinobin. Cyproconazole, Epoxiconazole, Flutriafolel, Pyraclostrobin,
Tebuconazole, Trifloxystrobin, Prothioconazole, Tetraconazole; Sugarbeet Herbicides: Chloridazon, Desmedipham, Ethofumesate, Phenmedipham, Triallate, Clopyralid, Fluazifop, Lenacil, Metamitron, Quinmerac, Cycloxydim, Triflusulfuron, Tepraloxydim, Quinalofop; Sugarbeet Insecticides: Imidacloprid, Clothianidin, Thiamethoxam, Thiacloprid, Acetamiprid, Dinetofuran, Deltamethrin, β-Cyfluthrin, γ/λ-Cyhalothrin, τ-Fluvalinate, Ethiprole, Spinosad, Spinotoram, Flubendiamide, Rynaxypyr, Cyazypyr, 4-[[6-Chlorpyridin-3-yl)methyl(2,2-difluorethyl)amino]furan-2(5H)-on.

"Pest" includes but is not limited to, insects, fungi, bacteria, nematodes, mites, ticks, and the like. Insect pests include insects selected from the orders Coleoptera, Diptera, Hymenoptera, Lepidoptera, Mallophaga, Homoptera, Hemiptera, Orthoptera, Thysanoptera, Dermaptera, Isoptera, Anoplura, Siphonaptera, Trichoptera, etc., particularly Coleoptera, Lepidoptera, and Diptera.

The order Coleoptera includes the suborders Adephaga and Polyphaga. Suborder Adephaga includes the superfamilies Caraboidea and Gyrinoidea, while suborder Polyphaga includes the superfamilies Hydrophiloidea, Staphylinoidae, Cantharoidea, Cleroidea, Elateroidea, Dascilloidea, Dryopoidea, Byrrhoidea, Cuculoidea, Meloidea, Mordelloidea, Tenebrionoidea, Bostrichoidea, Scarabaeoidea, Cerambycoidea, Chrysomeloidea, and Curculionoidea. Superfamily Caraboidea includes the families Cicindelidae, Carabidae, and Dytiscidae. Superfamily Gyrinoidea includes the family Gyrinidae. Superfamily Hydrophiloidea includes the family Hydrophilidae. Superfamily Staphylinoidae includes the families Silphidae and Staphylinidae. Superfamily Cantharoidea includes the families Cantharidae and Lampyridae. Superfamily Cleroidea includes the families Cleridae and Dermestidae. Superfamily Elateroidea includes the families Elateridae and Buprestidae. Superfamily Cuculoidea includes the family Coccinellidae. Superfamily Meloidea
includes the family *Meloidae*. Superfamily *Tenebrionoidea* includes the family
*Tenebrionidae*. Superfamily *Scarabaeoidea* includes the families *Passalidae* and *Scarabaeidae*. Superfamily *Cerambycoidea* includes the family *Cerambycidae*. Superfamily *Chrysomeloidea* includes the family *Chrysomelidae*. Superfamily *Curculionoidea* includes the families *Curculionidae* and *Scolytidae*.

The order *Diptera* includes the Suborders *Nematocera*, *Brachycera*, and *Cyclorrhapha*. Suborder *Nematocera* includes the families *Tipulidae*, *Psychodidae*, *Culicidae*, *Ceratopogonidae*, *Chironomidae*, *Simulidae*, *Bibionidae*, and *Cecidomyiidae*. Suborder *Brachycera* includes the families *Stratiomyidae*, *Tabanidae*, *Therevidae*, *Asilidae*, *Mydidae*, *Bombyliidae*, and *Dolichopodidae*. Suborder *Cyclorrhapha* includes the Divisions *Aschiza* and *Aschiza*. Division *Aschiza* includes the families *Phoridae*, *Syrphidae*, and *Conopidae*. Division *Aschiza* includes the Sections *Acalyptratae* and *Calyptratae*. Section *Acalyptratae* includes the families *Otitidae*, *Tephritidae*, *Agromyzidae*, and *Drosophilidae*. Section *Calyptratae* includes the families *Hippoboscidae*, *Oestridae*, *Tachinidae*, *Anthomyiidae*, *Sarcophagidae*, *Muscidae*, *Calliphoridae*, *Trypetidae*, *Sesiidae*, *Noctuidae*, *Lymantriidae*, *Sesiidae*, *Tineidae*, *Scoliidae*, *Tortricidae*, *Lycaenidae*, *Satyrinae*, *Tortricidae*, *Lycaenidae*, *Satyrinae*, *Sesiidae*, *Noctuidae*, *Lymantriidae*, *Sesiidae*, *Tineidae*, *Tortricidae*, *Lycaenidae*, *Satyrinae*, *Sesiidae*, *Noctuidae*, *Lymantriidae*, *Sesiidae*, *Tineidae*, *Tortricidae*, *Lycaenidae*, *Satyrinae*, *Sesiidae*, *Noctuidae*, *Lymantriidae*, *Sesiidae*, *Tineidae*, *Tortricidae*, *Lycaenidae*, *Satyrinae*, *Sesiidae*, *Noctuidae*, *Lymantriidae*, *Sesiidae*, *Tineidae*. Insect pests of the invention for the major crops include: *Maize*: *Ostrinia nubilalis*, European corn borer; *Agrotis ipsilon*, black cutworm; *Helicoverpa zea*, corn earworm; *Spodoptera frugiperda*, fall armyworm; *Diatraea grandiosella*, southwestern corn borer; *Elasmopalpus lignosellus*, lesser cornstalk borer; *Diabrotica saccharalis*, sugarcane borer; *Diabrotica virgifera*, western corn rootworm; *Diabrotica longicornis barberi*, northern corn rootworm; *Diabrotica undecimpunctata howardi*, southern corn rootworm; *Melanotus spp.*, wireworms; *Cyclocephala borealis*, northern masked chafer (white grub); *Cyclocephala immaculata*, southern masked chafer (white grub); *Popillia japonica*, Japanese beetle; *Chaetocnema pulicaria*, corn flea beetle; *Sphenophorus maidis*, maize billbug; *Rhopalosiphum maidis*, corn leaf aphid; *Anuraphis maidiradicis*, corn root aphid; *Blissus leucopterus leucopterus*, chinch bug; *Melanoplus femurrubrum*, redlegged grasshopper; *Melanoplus sanguinipes*, migratory grasshopper; *Hylemya platura*, seedcorn maggot; *Agromyza parvicornis*, corn blot leafminer; *Anaphothrips obscurus*, grass thrips;
Solenopsis milesta, thief ant; Tetranychus urticae, twospotted spider mite; Sorghum: Chilo partellus, sorghum borer; Spodoptera frugiperda, fall armyworm; Heterocoverpa zea, corn earworm; Elasmopalpus lignosellus, lesser cornstalk borer; Feltia subterranea, granulate cutworm; Phyllophaga crinita, white grub; Eleodes, Conoderus, and Aeolus spp., wireworms; Oulema melanopus, cereal leaf beetle; Chaetocnema pulicaria, corn flea beetle; Sphenophorus maidis, maize billbug; Rhopalosiphum maidis; corn leaf aphid; Sipha flava, yellow sugarcane aphid; Blissus leucopterus leucopterus, chinch bug; Contarinia sorghicola, sorghum midge; Tetanychus cinnabarinus, carmine spider mite; Tetanychus urticae, twospotted spider mite; Wheat: Pseudaletia unipunctata, army worm; Spodoptera frugiperda, fall armyworm; Elasmopalpus lignosellus, lesser cornstalk borer; Agrotis orthogonia, western cutworm; Elasmopalpus lignosellus, lesser cornstalk borer; Oulema melanopus, cereal leaf beetle; Hypera punctata, clover leaf weevil; Diabrotica undecimpunctata howardi, southern corn rootworm; Russian wheat aphid; Schizaphis graminum, greenbug; Macrosiphum avenae, English grain aphid; Melanoplus femur-rubrum, redlegged grasshopper; Melanoplus differentialis, differential grasshopper; Melanoplus sanguinipes, migratory grasshopper; Mayetiola destructor, Hessian fly; Sitodiplosis mosellana, wheat midge; Meromyza americana, wheat stem maggot; Hylemya coarctata, wheat bulb fly; Franklinkiella fusca, tobacco thrips; Cephus cinctus, wheat stem sawfly; Aceria tulipae, wheat curl mite; Sunflower: Suleima helianthana, sunflower bud moth; Homoeosoma electellum, sunflower moth; zygrogramma exclamationis, sunflower beetle; Bothyrus gibbosus, carrot beetle; Neolasioptera murtfeldtiana, sunflower seed midge; Cotton: Heliothis virescens, cotton budworm; Helicoverpa zea, cotton bollworm; Spodoptera exigua, beet armyworm; Pectinophora gossypiella, pink bollworm; Anthonomus grandis, boll weevil; Aphis gossypii, cotton aphid; Pseudatomoscelis seriatus, cotton fleahopper; Trialeurodes abutilonea, bandedwinged whitefly; Lygus lineolaris, tarnished plant bug; Melanoplus femur-rubrum, redlegged grasshopper; Melanoplus differentialis, differential grasshopper; Thrips tabaci, onion thrips; Franklinkiella fusca, tobacco thrips; Tetanychus cinnabarinus, carmine spider mite; Tetanychus urticae, twospotted spider mite; Rice: Diatraea saccharalis, sugarcane borer; Spodoptera frugiperda, fall armyworm; Helicoverpa zea, corn earworm; Colaspis brunnea, grape colaspis; Lissorhoptrus oryzophilus, rice water weevil; Sitophilus oryzae, rice weevil; Nephotettix nigropictus, rice leafhopper; Blissus leucopterus leucopterus, chinch bug;
Acrosternum hilare, green stink bug; Soybean: Pseudoplusia includens, soybean looper; Anticarsia gemmatalis, velvetbean caterpillar; Plathypena scabra, green cloverworm; Ostrinia nubilalis, European corn borer; Agrotis ipsilon, black cutworm; Spodoptera exigua, beet armyworm; Heliothis virescens, cotton budworm; Ostrinia nubilalis, European corn borer; Agrotis ipsilon, black cutworm; Plathypena scabra, green cloverworm; Myzus persicae, green peach aphid; Empoasca fabae, potato leafhopper; Acrosternum hilare, green stink bug; Melanoplus femurrubrum, redlegged grasshopper; Melanoplus differentialis, differential grasshopper; Hylemya platura, seedcorn maggot; Sericothrips variabilis, soybean thrips; Thrips tabaci, onion thrips; Tetranychus turkestani, strawberry spider mite; Tetranynchus urticae, twospotted spider mite; Barley: Ostrinia nubilalis, European corn borer; Agrotis ipsilon, black cutworm; Schizaphis graminum, greenbug; Blissus leucopterus leucopterus, chinch bug; Acrosternum hilare, green stink bug; Euschistus servus, brown stink bug; Delia platura, seedcorn maggot; Mayetiola destructor, Hessian fly; Petrobia latens, brown wheat mite; Oil Seed Rape: Brevicoryne brassicae, cabbage aphid; Phyllotreta cruciferae, Flea beetle; Mamestra configurata, Bertha armyworm; Plutella xylostella, Diamond-back moth; Delia ssp., Root maggots.

Nematodes include parasitic nematodes such as root-knot, cyst, and lesion nematodes, including Heterodera spp., Meloidogyne spp., and Globodera spp.; particularly members of the cyst nematodes, including, but not limited to, Heterodera glycines (soybean cyst nematode); Heterodera schachtii (beet cyst nematode); Heterodera avenae (cereal cyst nematode); and Globodera rostochiensis and Globodera pallida (potato cyst nematodes). Lesion nematodes include Pratylenchus spp.

Methods for increasing plant yield

Methods for increasing plant yield are provided. The methods comprise providing a plant or plant cell expressing a polynucleotide encoding the pesticidal polypeptide sequence disclosed herein and growing the plant or a seed thereof in a field infested with a pest against which said polypeptide has pesticidal activity. In some embodiments, the polypeptide has pesticidal activity against a lepidopteran, coleopteran, dipteran, hemipteran, or nematode pest, and said field is infested with a lepidopteran, hemipteran, coleopteran, dipteran, or nematode pest.
As defined herein, the "yield" of the plant refers to the quality and/or quantity of biomass produced by the plant. By "biomass" is intended any measured plant product. An increase in biomass production is any improvement in the yield of the measured plant product. Increasing plant yield has several commercial applications. For example, increasing plant leaf biomass may increase the yield of leafy vegetables for human or animal consumption. Additionally, increasing leaf biomass can be used to increase production of plant-derived pharmaceutical or industrial products. An increase in yield can comprise any statistically significant increase including, but not limited to, at least a 1% increase, at least a 3% increase, at least a 5% increase, at least a 10% increase, at least a 20% increase, at least a 30%, at least a 50%, at least a 70%, at least a 100% or a greater increase in yield compared to a plant not expressing the pesticidal sequence.

In specific methods, plant yield is increased as a result of improved pest resistance of a plant expressing a pesticidal protein disclosed herein. Expression of the pesticidal protein results in a reduced ability of a pest to infest or feed on the plant, thus improving plant yield.

The following examples are offered by way of illustration and not by way of limitation.

Example 1. Mutagenesis of the N-terminal portion of Axmi205

Axmi205 is a toxin active on western corn rootworm (WCRW) larvae (see U.S. Patent Publication No. 20110023184, which is herein incorporated by reference in its entirety). The nucleotide sequence for Axmi205 is set forth in SEQ ID NO: 1. The amino acid sequence for Axmi205 is set forth in SEQ ID NO: 2.

Three dimensional modeling and sequence alignments indicate that the N-terminal half of Axmi205 is homologous to pore-forming domains of perforins. The C-terminal half of Axmi205 shows no homologies, and its function is unknown. Other protein endotoxins that are active on insects contain a pore-forming domain and a receptor binding domain. It is conceivable that the C-terminal half of Axmi205 is involved in targeting Axmi205 to locations in WCRW where pore formation occurs.

A point mutant library targeting 30 positions in the C-terminal portion of Axmi205 was generated using the QUIKCHANGE® lightening mutagenesis kit
(Stratagene). Plasmid pAX701 encoding native Axmi205 in pRSFlb was mutagenized. The library had a total complexity of 506.

The pooled mutants, as well as pAX701, were transformed into BL21*DE3 cells and plated on LB+ Kanamycin (100µg/ml). Fresh colonies were picked into 8 ml LB + Kanamycin (100µg/ml) liquid medium and were grown in 24 deep well blocks at 37 degrees C and 300 rpm until an OD600 nm of 0.3 was reached. IPTG was added to a final concentration of 0.5 mM and the cultures were incubated for an additional 18 hours at 20 degrees C. The OD600 nm was determined and the cells were collected by centrifugation (10 minutes at 4000 rpm, 4 degrees C). The cell pellets were resuspended in 20 mM Tris/HCl pH 7.4, 150 mM NaCl, 1 mM DTT at a density of 20 OD600/ml. The cells were disrupted by bead beating and soluble extracts were obtained after centrifugation at 4500 rpm for 15 minutes at 4 degrees C.

The extracts were assayed for activity against WCRW at four replicates per variant. After 5 and 6 days, rootworm toxicity scores were determined by averaging the scores from four replicates. Eleven hundred and thirty-nine variants were screened in this primary screen, providing a 2.2x coverage of the library. Variants scoring higher than the wildtype Axmi205 were sequenced and re-assayed. Scale-up assays were then performed to rank mutants relative to wildtype Axmi205 and Axmi205(evo25) (U.S. Patent Publication No. 201 10023 184 and set forth herein as SEQ ID NO:3). Scale-up assay data is shown in Tables 1 and 2 for the top variants that scored above wildtype Axmi205 in the primary assay, re-assay and both scale-ups.

</table>
Variant Axmi205(evo30) showed improved activity compared to Axmi205(evo25). It carries the mutation V467L. The nucleotide sequence encoding Axmi205(evo30) is set forth in SEQ ID NO:4. The amino acid sequence is set forth in SEQ ID NO:7. The next most active variants are Axmi205 PMlibl PoolIG2_p2alpha (mutation S468L; SEQ ID NO: 10), Axmi205 PMlibl PoolIG2_plcl (mutation V467T; SEQ ID NO: 11) and Axmi205 PMlibl PoolIG2_pla4 (mutation R464N; SEQ ID NO: 12). Out of the 30 positions mutagenized, the improved variants carry mutations that cluster with Axmi205(evo25) (mutation V467A). These results suggest that positions 467 and 468 are linked to improved activity in Axmi205.

Example 2. Random mutagenesis of Axmi205

Whole gene:
Random PCR mutagenesis of the entire Axmi205 protein was carried out. Eleven hundred and sixty-six variants were assayed at the four-replicate level, reassayed and scaled up to identify variant Axmi205(evo35) as having improved properties (Table 2). The nucleotide sequence encoding Axmi205(evo35) is set forth in SEQ ID NO:6. The amino acid sequence is set forth in SEQ ID NO:9.

Example 3. Mutagenesis of the C-terminal portion of Axmi205

In the N-terminal pore-forming domain of perforin-type toxins, several alpha-helices are known to interact with the membrane of target organisms. These helices re-arrange to form the transmembrane channel of perforin-type toxins. These helices were targeted for mutagenesis. Thirty-nine positions were mutagenized for a total diversity of 648. One thousand fifty-five variants were screened, 116 hits were reassayed and 34 hits scaled up. Of these variants, Axmi205(evo34) was the most active variant (Table 2), and showed improved expression relative to the expression of Axmi205wt. The nucleotide sequence encoding Axmi205(evo34) is set forth in SEQ ID NO:5. The amino acid sequence is set forth in SEQ ID NO:8.

Example 4. Additional assays for Pesticidal Activity

The nucleotide sequences of the invention can be tested for their ability to produce pesticidal proteins. The ability of a pesticidal protein to act as a pesticide upon a pest is often assessed in a number of ways. One way well known in the art is to perform a feeding assay. In such a feeding assay, one exposes the pest to a sample containing either compounds to be tested or control samples. Often this is performed by placing the material to be tested, or a suitable dilution of such material, onto a material that the pest will ingest, such as an artificial diet. The material to be tested may be composed of a liquid, solid, or slurry. The material to be tested may be placed upon the surface and then allowed to dry. Alternatively, the material to be tested may be mixed with a molten artificial diet, then dispensed into the assay chamber. The assay chamber may be, for example, a cup, a dish, or a well of a microtiter plate.

Assays for sucking pests (for example aphids) may involve separating the test material from the insect by a partition, ideally a portion that can be pierced by the sucking mouth parts of the sucking insect, to allow ingestion of the test material. Often the test material is mixed with a feeding stimulant, such as sucrose, to promote ingestion of the test compound.

Other types of assays can include microinjection of the test material into the mouth, or gut of the pest, as well as development of transgenic plants, followed by test of the ability of the pest to feed upon the transgenic plant. Plant testing may involve isolation of the plant parts normally consumed, for example, small cages attached to a leaf, or isolation of entire plants in cages containing insects.
Other methods and approaches to assay pests are known in the art, and can be found, for example in Robertson and Preisler, eds. (1992) *Pesticide bioassays with arthropods*, CRC, Boca Raton, FL. Alternatively, assays are commonly described in the journals *Arthropod Management Tests* and *Journal of Economic Entomology* or by discussion with members of the Entomological Society of America (ESA).

Example 5. Vectoring of Genes for Plant Expression

The coding regions of the invention are connected with appropriate promoter and terminator sequences for expression in plants. Such sequences are well known in the art and may include the rice actin promoter or maize ubiquitin promoter for expression in monocots, the *Arabidopsis* UBQ3 promoter or CaMV 35S promoter for expression in dicots, and the nos or Pin II terminators. Techniques for producing and confirming promoter - gene - terminator constructs also are well known in the art.

In one aspect of the invention, synthetic DNA sequences are designed and generated. These synthetic sequences have altered nucleotide sequence relative to the parent sequence, but encode proteins that are essentially identical to the parent protein (e.g., SEQ ID NO:7-12).

In another aspect of the invention, modified versions of the synthetic genes are designed such that the resulting peptide is targeted to a plant organelle, such as the endoplasmic reticulum or the apoplast. Peptide sequences known to result in targeting of fusion proteins to plant organelles are known in the art. For example, the N-terminal region of the acid phosphatase gene from the White Lupin *Lupinus albus* (GENBANK® ID GL14276838, Miller *et al.* (2001) *Plant Physiology* 127: 594-606) is known in the art to result in endoplasmic reticulum targeting of heterologous proteins. If the resulting fusion protein also contains an endoplasmic reticulum retention sequence comprising the peptide N-terminus-lysine-aspartic acid-glutamic acid-leucine (i.e., the "KDEL" motif, SEQ ID NO: 13) at the C-terminus, the fusion protein will be targeted to the endoplasmic reticulum. If the fusion protein lacks an endoplasmic reticulum targeting sequence at the C-terminus, the protein will be targeted to the endoplasmic reticulum, but will ultimately be sequestered in the apoplast.

Thus, this gene encodes a fusion protein that contains the N-terminal thirty-one amino acids of the acid phosphatase gene from the White Lupin *Lupinus albus* (GENBANK® ID GI: 14276838 , Miller *et al*, 2001, supra) fused to the N-terminus...
of the amino acid sequence of the invention, as well as the KDEL sequence at the C-terminus. Thus, the resulting protein is predicted to be targeted the plant endoplasmic reticulum upon expression in a plant cell.

The plant expression cassettes described above are combined with an appropriate plant selectable marker to aid in the selection of transformed cells and tissues, and ligated into plant transformation vectors. These may include binary vectors from *Agrobacterium-mQdiatQd* transformation or simple plasmid vectors for aerosol or biolistic transformation.

Example 6. Vectoring genes for Plant Expression

The coding region DNA of the genes of the invention are operably connected with appropriate promoter and terminator sequences for expression in plants. Such sequences are well known in the art and may include the rice actin promoter or maize ubiquitin promoter for expression in monocots, the *Arabidopsis UBQ3* promoter or CaMV 35S promoter for expression in dicots, and the nos or Pinll terminators. Techniques for producing and confirming promoter - gene - terminator constructs also are well known in the art.

The plant expression cassettes described above are combined with an appropriate plant selectable marker to aid in the selections of transformed cells and tissues, and ligated into plant transformation vectors. These may include binary vectors from *Agrobacterium-mQdiatQd* transformation or simple plasmid vectors for aerosol or biolistic transformation.

Example 7. Transformation of Maize Cells with the pesticidal protein genes described herein

Maize ears are best collected 8-12 days after pollination. Embryos are isolated from the ears, and those embryos 0.8-1.5 mm in size are preferred for use in transformation. Embryos are plated scutellum side-up on a suitable incubation media, such as DN62A5S media (3.98 g/L N 6 Salts; 1 mL/L (of 1000x Stock) N 6 Vitamins; 800 mg/L L-Asparagine; 100 mg/L Myo-inositol; 1.4 g/L L-Proline; 100 mg/L Casamino acids; 50 g/L sucrose; 1 mL/L (of 1 mg/mL Stock) 2,4-D). However, media and salts other than DN62A5S are suitable and are known in the art. Embryos
are incubated overnight at 25°C in the dark. However, it is not necessary per se to incubate the embryos overnight.

The resulting explants are transferred to mesh squares (30-40 per plate), transferred onto osmotic media for about 30-45 minutes, then transferred to a beaming plate (see, for example, PCT Publication No. WO/01385 14 and U.S. Patent No. 5,240,842).

DNA constructs designed to the genes of the invention in plant cells are accelerated into plant tissue using an aerosol beam accelerator, using conditions essentially as described in PCT Publication No. WO/01385 14. After beaming, embryos are incubated for about 30 min on osmotic media, and placed onto incubation media overnight at 25°C in the dark. To avoid unduly damaging beamed explants, they are incubated for at least 24 hours prior to transfer to recovery media. Embryos are then spread onto recovery period media, for about 5 days, 25°C in the dark, then transferred to a selection media. Explants are incubated in selection media for up to eight weeks, depending on the nature and characteristics of the particular selection utilized. After the selection period, the resulting callus is transferred to embryo maturation media, until the formation of mature somatic embryos is observed. The resulting mature somatic embryos are then placed under low light, and the process of regeneration is initiated by methods known in the art. The resulting shoots are allowed to root on rooting media, and the resulting plants are transferred to nursery pots and propagated as transgenic plants.

The pH of the solution is adjusted to pH 5.8 with 1N KOH/1N KC1, Gelrite (Sigma) is added at a concentration up to 3g/L, and the media is autoclaved. After cooling to 50°C, 2 ml/L of a 5 mg/ml stock solution of silver nitrate (Phytotechnology Labs) is added.

Example 8. Transformation of genes of the invention in Plant Cells by Agrobacterium-MQdiatQd Transformation

Ears are best collected 8-12 days after pollination. Embryos are isolated from the ears, and those embryos 0.8-1.5 mm in size are preferred for use in transformation. Embryos are plated scutellum side-up on a suitable incubation media, and incubated overnight at 25°C in the dark. However, it is not necessary per se to incubate the embryos overnight. Embryos are contacted with an Agrobacterium strain containing the appropriate vectors for Ti plasmid mediated transfer for about 5-10 min, and then plated onto co-cultivation media for about 3 days (25°C in the dark). After co-cultivation, explants are transferred to recovery period media for about five days (at 25°C in the dark). Explants are incubated in selection media for up to eight weeks, depending on the nature and characteristics of the particular selection utilized. After the selection period, the resulting callus is transferred to embryo maturation media, until the formation of mature somatic embryos is observed. The resulting mature somatic embryos are then placed under low light, and the process of regeneration is initiated as known in the art.

All publications and patent applications mentioned in the specification are indicative of the level of skill of those skilled in the art to which this invention pertains. All publications and patent applications are herein incorporated by reference to the same extent as if each individual publication or patent application was specifically and individually indicated to be incorporated by reference.

Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, it will be obvious that certain changes and modifications may be practiced within the scope of the appended claims.
THAT WHICH IS CLAIMED:

1. A recombinant nucleic acid molecule comprising a nucleotide sequence that encodes a polypeptide that is a variant of SEQ ID NO:2, wherein said polypeptide has improved pesticidal activity relative to SEQ ID NO:2.

2. The recombinant nucleic acid molecule of claim 1, wherein said nucleotide sequence is a synthetic sequence that has been designed for expression in a plant.

3. The recombinant nucleic acid molecule of claim 2, wherein said nucleotide sequence is selected from SEQ ID NO:4, 5, or 6, or a nucleotide sequence encoding an amino acid sequence selected from SEQ ID NO:7, 8, 9, 10, 11, or 12.

4. The recombinant nucleic acid molecule of claim 1, wherein said nucleotide sequence is operably linked to a promoter capable of directing expression of said nucleotide sequence in a plant cell.

5. The recombinant nucleic acid molecule of claim 4, further comprising a nucleotide sequence encoding a heterologous polypeptide.

6. A host cell that contains the recombinant nucleic acid molecule of claim 4.

7. The host cell of claim 6 that is a bacterial host cell.

8. The host cell of claim 6 that is a plant cell.

9. A transgenic plant comprising the host cell of claim 8.

10. The transgenic plant of claim 9, wherein said plant is selected from the group consisting of maize, sorghum, wheat, cabbage, sunflower, tomato, crucifers,
peppers, potato, cotton, rice, soybean, sugarbeet, sugarcane, tobacco, barley, and oilseed rape.

11. A recombinant polypeptide with pesticidal activity, wherein said polypeptide is a variant of SEQ ID NO:2, wherein said polypeptide has improved pesticidal activity relative to SEQ ID NO:2.

12. The polypeptide of claim 11 further comprising heterologous amino acid sequences.

13. An antibody that selectively binds to the polypeptide of claim 11.

15. The composition of claim 14, wherein said composition is selected from the group consisting of a powder, dust, pellet, granule, spray, emulsion, colloid, and solution.

16. The composition of claim 14, wherein said composition is prepared by desiccation, lyophilization, homogenization, extraction, filtration, centrifugation, sedimentation, or concentration of a culture of Bacillus thuringiensis cells.

17. The composition of claim 14, comprising from about 1% to about 99% by weight of said polypeptide.

18. A method for controlling a lepidopteran or coleopteran pest population comprising contacting said population with a pesticidally-effective amount of the polypeptide of claim 11.

19. A method for killing a lepidopteran or coleopteran pest, comprising contacting said pest with, or feeding to said pest, a pesticidally-effective amount of the polypeptide of claim 11.
20. A method for producing a polypeptide with pesticidal activity, comprising culturing the host cell of claim 6 under conditions in which the nucleic acid molecule encoding the polypeptide is expressed.

21. A plant having stably incorporated into its genome a DNA construct comprising a nucleotide sequence that encodes a polypeptide that is a variant of SEQ ID NO:2, wherein said polypeptide has improved pesticidal activity relative to SEQ ID NO:2; wherein said nucleotide sequence is operably linked to a promoter that drives expression of a coding sequence in a plant cell.

22. The plant of claim 21, wherein said plant is a plant cell.

23. A transgenic seed of the plant of claim 21, wherein said seed comprises a nucleotide sequence selected from SEQ ID NO:4, 5, or 6, or a nucleotide sequence encoding an amino acid sequence selected from SEQ ID NO:7, 8, 9, 10, 11, or 12.

24. A method for protecting a plant from an insect pest, comprising expressing in a plant or cell thereof a nucleotide sequence that encodes a polypeptide that is a variant of SEQ ID NO:2, wherein said polypeptide has improved pesticidal activity relative to SEQ ID NO:2.

25. The method of claim 24, wherein said plant produces a pesticidal polypeptide having pesticidal activity against a lepidopteran or coleopteran pest.

26. A method for increasing yield in a plant comprising growing in a field a plant of or a seed thereof having stably incorporated into its genome a DNA construct comprising a nucleotide sequence that encodes a protein having pesticidal activity, wherein said nucleotide sequence encodes a polypeptide that is a variant of SEQ ID NO:2, wherein said polypeptide has improved pesticidal activity relative to SEQ ID NO:2; wherein said field is infested with a pest against which said polypeptide has pesticidal activity.
27. The method of claim 24, wherein said nucleotide sequence is selected from SEQ ID NO:4, 5, or 6, or a nucleotide sequence encoding an amino acid sequence selected from SEQ ID NO:7, 8, 9, 10, 11, or 12.

28. The method of claim 26, wherein said nucleotide sequence is selected from SEQ ID NO:4, 5, or 6, or a nucleotide sequence encoding an amino acid sequence selected from SEQ ID NO:7, 8, 9, 10, 11, or 12.
