MITOGENIC OXYGENASE REGULATORS

10

The U.S. Government has a paid-up license in this invention and the right in limited circumstances to require the patent owner to license others on reasonable terms as provided for by the terms of National Institutes of Health grants HL38206, HL58000, and CA84138.

15

TECHNICAL FIELD

The present invention relates to the field of normal and abnormal cell growth, in particular mitogenic regulation. The present invention provides the following: nucleotide sequences encoding for the production of enzymes that are mitogenic regulators; amino acid sequences of these enzymes; vectors containing these nucleotide sequences; methods for transfecting cells with vectors that produce these enzymes; transfected cells; methods for administering these transfected cells to animals to induce tumor formation; antibodies to these enzymes that are useful for detecting and measuring levels of these enzymes, and for binding to cells possessing extracellular epitopes of these enzymes; and assays for screening for effectors of these enzymes.

20

25

BACKGROUND OF THE INVENTION

Reactive oxygen intermediates (ROI) are cytotoxic and mutagenic. ROIs modify and damage critical biomolecules including DNA and lipids. They are partial reduction products of oxygen: 1 electron reduces O_2 to form superoxide (O_2^-), and 2 electrons reduce O_2 to form hydrogen peroxide (H_2O_2). The cytotoxic property of ROI is exploited by phagocytes, which generate large amounts of superoxide and hydrogen peroxide as part of their armory of bactericidal mechanisms. ROI have been considered an accidental byproduct of metabolism, particularly mitochondrial respiration. Recent studies give evidence for regulated enzymatic generation of O_2^- and its conversion to H_2O_2 in a variety of cells. The conversion of O_2^- to H_2O_2 can also occur spontaneously, but is markedly accelerated by superoxide dismutase (SOD). Exposure of cells to platelet derived growth factor and epidermal growth factor induces the production of H_2O_2 , which activates components of signaling pathways including p42/p44 MAPK and tyrosine phosphorylation.

Several biological systems generate reactive oxygen. Exposure of neutrophils to bacteria or to various soluble mediators such as formyl-Met-Leu-Phe or phorbol esters activates a massive consumption of oxygen, termed the respiratory burst, to initially generate superoxide, with secondary generation of H_2O_2 , HOCl and hydroxyl radical. The enzyme responsible for this oxygen consumption is the respiratory burst oxidase (nicotinamide adenine dinucleotide phosphate-reduced form (NADPH) oxidase).

There is also growing evidence for the generation of ROI by non-phagocytic cells, particularly in situations related to cell proliferation. Significant generation of H_2O_2 , O_2^- , or both have been noted in some cell types. Fibroblasts and human endothelial cells show increased release of superoxide in response to cytokines such as interleukin-1 or tumor necrosis factor (TNF) (Meier et al. (1989) *Biochem J.* 263, 539-545.; Matsubara et al. (1986) *J. Immun.* 137, 3295-3298). Ras-transformed fibroblasts show increased superoxide release compared with control fibroblasts (Irani, et al. (1997) *Science* 275, 1649-1652). Rat vascular smooth muscle cells show

increased H_2O_2 release in response to PDGF (Sundaresan et al. (1995) *Science* 270, 296-299) and angiotensin II (Griendling et al. (1994) *Circ. Res.* 74, 1141-1148; Fukui et al. (1997) *Circ. Res.* 80, 45-51; Ushio-Fukai et al. (1996) *J. Biol. Chem.* 271, 23317-23321), and H_2O_2 in these cells is associated with increased proliferation rate. H_2O_2 in the transformed fibroblasts and in vascular smooth muscle cells is associated with an increased proliferation rate. The occurrence of ROI in a variety of cell types is summarized in Table 1 (adapted from Burdon, R. (1995) *Free Radical Biol. Med.* 18, 775-794).

TABLE 1

ROI generated by neutrophils have a cytotoxic function. While ROI are normally directed at the invading microbe, ROI can also induce tissue damage (e.g., in inflammatory conditions such as arthritis, shock, lung disease, and inflammatory bowel disease) or may be involved in tumor initiation or promotion, due to damaging effects on DNA. Nathan (Szatrowski et al. (1991) *Canc. Res.* 51, 794-798) proposed that the generation of ROI in tumor cells may contribute to the hypermutability seen in tumors, and may therefore contribute to tumor heterogeneity, invasion and metastasis.

In addition to cytotoxic and mutagenic roles, ROI have ideal properties as signal molecules: 1) they are generated in a controlled manner in response to upstream signals; 2) the signal can be terminated by rapid metabolism of O_2^- and H_2O_2 by SOD and catalase/peroxidases; 3) they elicit downstream effects on target molecules, e.g., redox-sensitive regulatory proteins such as

NFκ-B and AP-1 (Schreck et al. (1991) *EMBO J.* 10, 2247-2258; Schmidt et al. (1995) *Chemistry & Biology* 2, 13-22). Oxidants such as O_2^- and H_2O_2 have a relatively well defined signaling role in bacteria, operating via the SoxI/II regulon to regulate transcription.

5 ROI appear to have a direct role in regulating cell division, and may function as mitogenic signals in pathological conditions related to growth. These conditions include cancer and cardiovascular disease. O_2^- is generated in endothelial cells in response to cytokines, and might play a role in angiogenesis (Matsubara et al. (1986) *J. Immun.* 137, 3295-3298). O_2^- and
10 H_2O_2 are also proposed to function as "life-signals", preventing cells from undergoing apoptosis (Matsubara et al. (1986) *J. Immun.* 137, 3295-3298). As discussed above, many cells respond to growth factors (e.g., platelet derived growth factor (PDGF), epidermal derived growth factor (EGF), angiotensin II, and various cytokines) with both increased production of O_2^- / H_2O_2 and
15 increased proliferation. Inhibition of ROI generation prevents the mitogenic response. Exposure to exogenously generated O_2^- and H_2O_2 results in an increase in cell proliferation. A partial list of responsive cell types is shown below in Table 2 (adapted from Burdon, R. (1995) *Free Radical Biol. Med.* 18, 775-794).

30 While non-transformed cells can respond to growth factors and cytokines with the production of ROI, tumor cells appear to produce ROI in an

uncontrolled manner. A series of human tumor cells produced large amounts of hydrogen peroxide compared with non-tumor cells (Szatrowski et al. (1991) *Canc. Res.* 51, 794-798). Ras-transformed NIH 3T3 cells generated elevated amounts of superoxide, and inhibition of superoxide generation by several mechanisms resulted in a reversion to a "normal" growth phenotype.

O_2^- has been implicated in maintenance of the transformed phenotype in cancer cells including melanoma, breast carcinoma, fibrosarcoma, and virally transformed tumor cells. Decreased levels of the manganese form of SOD (MnSOD) have been measured in cancer cells and *in vitro*-transformed cell lines, predicting increased O_2^- levels (Burdon, R. (1995) *Free Radical Biol. Med.* 18, 775-794). MnSOD is encoded on chromosome 6q25 which is very often lost in melanoma. Overexpression of MnSOD in melanoma and other cancer cells (Church et al. (1993) *Proc. of Natl. Acad. Sci.* 90, 3113-3117; Fernandez-Pol et al. (1982) *Canc. Res.* 42, 609-617; Yan et al. (1996) *Canc. Res.* 56, 2864-2871) resulted in suppression of the transformed phenotype.

ROI are implicated in the growth of vascular smooth muscle associated with hypertension, atherosclerosis, and restenosis after angioplasty. O_2^- generation is seen in rabbit aortic adventitia (Pagano et al. (1997) *Proc. Natl. Acad. Sci.* 94, 14483-14488). Vascular endothelial cells release O_2^- in response to cytokines (Matsubara et al. (1986) *J. Immun.* 137, 3295-3298). O_2^- is generated by aortic smooth muscle cells in culture, and increased O_2^- generation is stimulated by angiotensin II which also induces cell hypertrophy. In a rat model system, infusion of angiotensin II leads to hypertension as well as increased O_2^- generation in subsequently isolated aortic tissue (Ushio-Fukai et al. (1996) *J. Biol. Chem.* 271, 23317-23321.; Yu et al. (1997) *J. Biol. Chem.* 272, 27288-27294). Intravenous infusion of a form of SOD that localizes to the vasculature or an infusion of an O_2^- scavenger prevented angiotensin II induced hypertension and inhibited ROI generation (Fukui et al. (1997) *Circ. Res.* 80, 45-51).

The neutrophil NADPH oxidase, also known as phagocyte respiratory burst oxidase, provides a paradigm for the study of the specialized enzymatic

ROI-generating system. This extensively studied enzyme oxidizes NADPH and reduces oxygen to form O_2^- . NADPH oxidase consists of multiple proteins and is regulated by assembly of cytosolic and membrane components. The catalytic moiety consists of flavocytochrome b_{558} , an integral plasma
5 membrane enzyme comprised of two components: gp91phox (gp refers to glycoprotein; phox is an abbreviation of the words phagocyte and oxidase) and p22phox (p refers to protein). gp91phox contains 1 flavin adenine dinucleotide (FAD) and 2 hemes as well as the NADPH binding site. p22phox has a C-terminal proline-rich sequence which serves as a binding site for
10 cytosolic regulatory proteins. The two cytochrome subunits, gp91phox and p22phox appear to stabilize one another, since the genetic absence of either subunit, as in the inherited disorder chronic granulomatous disease (CGD), results in the absence of the partner subunit (Yu et al. (1997) *J. Biol. Chem.* 272, 27288-27294). Essential cytosolic proteins include p47phox, p67phox
15 and the small GTPase Rac, of which there are two isoforms. p47phox and p67phox both contain SH₃ regions and proline-rich regions which participate in protein interactions governing assembly of the oxidase components during activation. The neutrophil enzyme is regulated in response to bacterial phagocytosis or chemotactic signals by phosphorylation of p47phox, and
20 perhaps other components, as well as by guanine nucleotide exchange to activate the GTP-binding protein Rac.

The origin of ROI in non-phagocytic tissues is unproven, but the occurrence of phagocyte oxidase components has been evaluated in several systems by immunochemical methods, Northern blots and reverse
25 transcriptase-polymerase chain reaction (RT-PCR). The message for p22phox is expressed widely, as is that for Rac1. Several cell types that are capable of O_2^- generation have been demonstrated to contain all of the phox components including gp91phox, as summarized below in Table 3. These cell types include endothelial cells, aortic adventitia and lymphocytes.

30

TABLE 3

	<u>Tissue</u>	<u>gp91phox</u>	<u>p22phox</u>	<u>p47phox</u>	<u>p67phox</u>
	neutrophil	+ ^{1,2}	+ ^{1,2}	+ ^{1,2}	+ ^{1,2}

1= protein expression shown. 2= mRNA expression shown.

However, a distinctly different pattern is seen in several other cell types shown in Table 3 including glomerular mesangial cells, rat aortic smooth muscle and fibroblasts. In these cells, expression of gp91phox is absent while p22phox and in some cases cytosolic phox components have been demonstrated to be present. Since gp91phox and p22phox stabilize one another in the neutrophil, there has been much speculation that some molecule, possibly related to gp91phox, accounts for ROI generation in glomerular mesangial cells, rat aortic smooth muscle and fibroblasts (Ushio-Fukai et al. (1996) *J. Biol. Chem.* 271, 23317-23321). Investigation of fibroblasts from a patient with a genetic absence of gp91phox provides proof that the gp91phox subunit is not involved in ROI generation in these cells (Emmendorffer et al. (1993) *Eur. J. Haematol.* 51, 223-227). Depletion of p22phox from vascular smooth muscle using an antisense approach indicated that this subunit participates in ROI generation in these cells, despite the absence of detectable gp91phox (Ushio-Fukai et al. (1996) *J. Biol. Chem.* 271, 23317-23321). At this time the molecular candidates possibly related to gp91phox and involved in ROI generation in these cells are unknown.

Accordingly, what is needed is the identity of the proteins involved in ROI generation, particularly in non-phagocytic tissues and cells. What is also needed are the nucleotide sequences encoding for these proteins, and the primary sequences of the proteins themselves. Also needed are vectors
5 designed to include nucleotides encoding for these proteins. Probes and PCR primers derived from the nucleotide sequence are needed to detect, localize and measure nucleotide sequences, including mRNA, involved in the synthesis of these proteins. In addition, what is needed is a means to transfect cells with these vectors. What is also needed are expression systems for production of
10 these molecules. Also needed are antibodies directed against these molecules for a variety of uses including localization, detection, measurement and passive immunization.

SUMMARY OF THE INVENTION

15 The present invention solves the problems described above by providing a novel family of nucleotide sequences and proteins, termed Nox proteins, encoded by these nucleotide sequences. In particular the present invention provides compositions comprising the nucleotide sequences SEQ ID NO:1, SEQ ID NO:3, or SEQ ID NO:5, and conservative substitutions and
20 fragments thereof, wherein SEQ ID NO:1 and fragments thereof code for the expression of the protein comprising SEQ ID NO:2 and fragments thereof; and SEQ ID NO:3 and fragments thereof code for the expression of the protein comprising SEQ ID NO:4 and fragments thereof. SEQ ID NO:5 is the promoter sequence for Nox 1. While not wanting to be bound by the following
25 statement, it is believed that these Nox proteins, SEQ ID NOs: 2 and 4, and fragments thereof, are involved in ROI production. The present invention also provides vectors containing these nucleotide sequences, cells transfected with these vectors which produce the proteins comprising SEQ ID NO:2 and SEQ ID NO:4, or fragments thereof, and antibodies to these proteins and fragments
30 thereof. The present invention also provides methods for stimulating cellular proliferation by administering vectors encoded for production of the proteins

comprising SEQ ID NO:2 or SEQ ID NO:4, and fragments thereof. The present invention further provides methods for stimulating cellular proliferation by administering the proteins comprising SEQ ID NO:2 or SEQ ID NO:4, and fragments thereof. The nucleotides and antibodies of the present invention are useful for the detection, localization and measurement of the nucleic acids encoding for the production of the proteins of the present invention, and also for the detection, localization and measurement of the proteins of the present invention. These nucleotides and antibodies can be combined with other reagents in kits for the purposes of detection, localization and measurement.

Most particularly, the present invention involves a method for regulation of cell division or cell proliferation by modifying the activity or expression of the proteins described as SEQ ID NO:2 or SEQ ID NO:4, or fragments thereof. These proteins, in their naturally occurring or expressed forms, are expected to be useful in drug development, for example for screening of chemical and drug libraries by observing inhibition of the activity of these enzymes. Such chemicals and drugs would likely be useful as treatments for cancer, prostatic hypertrophy, benign prostatic hypertrophy, hypertension, atherosclerosis and many other disorders involving abnormal cell growth or proliferation as described below. The entire expressed protein may be useful in these assays. Portions of the molecule which may be targets for inhibition or modification include, but are not limited to, the binding site for pyridine nucleotides (NADPH or NADH), the flavoprotein domain (approximately the C-terminal 265 amino acids), and/or the binding or catalytic site for flavin adenine dinucleotide (FAD).

The present invention further comprises the creation of reporter-promoter constructs for use in assays to measure the activity of compounds. The method of the present invention may additionally be used for the development of drugs or other therapies for the treatment of conditions associated with abnormal growth including, but not limited to, cancer, psoriasis, prostatic hypertrophy, benign prostatic hypertrophy, cardiovascular

disease, proliferation of vessels, including but not limited to blood vessels and lymphatic vessels, arteriovenous malformation, vascular problems associated with the eye, atherosclerosis, hypertension, and restenosis following angioplasty. The enzymes of the present invention are excellent targets for the
5 development of drugs and other agents which may modulate the activity of these enzymes. It is to be understood that modulation of activity may result in enhanced, diminished or absence of enzymatic activity. Modulation of the activity of these enzymes may be useful in treatment of conditions associated with abnormal growth.

10 Drugs which affect the activity of the enzymes represented in SEQ ID NO:2, SEQ ID NO:4, or fragments thereof, may also be combined with other therapeutics in the treatment of specific conditions. For example, these drugs may be combined with angiogenesis inhibitors in the treatment of cancer, with antihypertensives for the treatment of hypertension, and with cholesterol
15 lowering drugs for the treatment of atherosclerosis.

Accordingly, an object of the present invention is to provide nucleotide sequences, or fragments thereof, encoding for the production of proteins, or fragments thereof, that are involved in ROI production.

20 Another object of the present invention is to provide vectors containing these nucleotide sequences, or fragments thereof.

Yet another object of the present invention is to provide cells transfected with these vectors.

Still another object of the present invention is to administer cells transfected with these vectors to animals and humans.

25 Another object of the present invention is to provide proteins, or fragments thereof, that are involved in ROI production.

Still another object of the present invention is to provide antibodies, including monoclonal and polyclonal antibodies, or fragments thereof, raised against proteins, or fragments thereof, that are involved in ROI production.

30 Another object of the present invention is to administer genes containing nucleotide sequences, or fragments thereof, encoding for the

production of proteins, or fragments thereof, that are involved in ROI production, to animals and humans, and also to cells obtained from animals and humans.

Another object of the present invention is to administer antisense
5 complimentary sequences of genes containing nucleotide sequences, or fragments thereof, encoding for the production of proteins, or fragments thereof, that are involved in ROI production, to animals and humans and also to cells obtained from animals and humans.

Yet another object of the present invention is to provide a method for
10 stimulating or inhibiting cellular proliferation by administering vectors containing nucleotide sequences, or fragments thereof, encoding for the production of proteins, or fragments thereof, that are involved in ROI production, to animals and humans. It is also an object of the present invention to provide a method for stimulating or inhibiting cellular proliferation by
15 administering vectors containing antisense complimentary sequences of nucleotide sequences, or fragments thereof, encoding for the production of proteins, or fragments thereof, that are involved in ROI production, to animals and humans. These methods of stimulating cellular proliferation are useful for a variety of purposes, including but not limited to, developing animal models
20 of tumor formation, stimulating cellular proliferation of blood marrow cells following chemotherapy or radiation, or in cases of anemia.

Still another object of the present invention is to provide antibodies useful in immunotherapy against cancers expressing the proteins represented in SEQ ID NO:2, SEQ ID NO:4, or fragments thereof.

25 Yet another object of the present invention is to provide nucleotide probes useful for the detection, localization and measurement of nucleotide sequences, or fragments thereof, encoding for the production of proteins, or fragments thereof, that are involved in ROI production.

Another object of the present invention is to provide antibodies useful
30 for the detection, localization and measurement of nucleotide sequences, or

fragments thereof, encoding for the production of proteins, or fragments thereof, that are involved in ROI production.

Another object of the present invention is to provide kits useful for detection of nucleic acids including the nucleic acids including the nucleic acids represented in SEQ ID NO:1, SEQ ID NO:3, or fragments thereof, that
5 encode for proteins, or fragments thereof, that are involved in ROI production.

A further object of the present invention is to provide kits useful for detection of nucleic acids including nucleic acids represented in SEQ ID NO:5, or fragments thereof, representing the promoter region of Nox 1.

10 Still another object of the present invention is to provide kits useful for the localization of nucleic acids including the nucleic acids represented in SEQ ID NO:1, SEQ ID NO:3, or fragments thereof, that encode for proteins, or fragments thereof that are involved in ROI production.

Yet another object of the present invention is to provide kits useful for
15 the localization of nucleic acids including the nucleic acids represented in SEQ ID NO:5 or fragments thereof, representing the promoter region of Nox 1.

Another object of the present invention is to provide kits useful for detection of proteins, including the proteins represented in SEQ ID NO:2 and SEQ ID NO:4, or fragments thereof, that are involved in ROI production.

20 Yet another object of the present invention is to provide kits useful for detection and measurement of proteins, including the proteins represented in SEQ ID NO:2 and SEQ ID NO:4, or fragments thereof, that are involved in ROI production.

Still another object of the present invention is to provide kits useful for
25 localization of proteins, including the proteins represented in SEQ ID NO:2 and SEQ ID NO:4, or fragments thereof, that are involved in ROI production.

Yet another object of the present invention is to provide kits useful for the detection, measurement or localization of nucleic acids, or fragments thereof, encoding for proteins, or fragments thereof, that are involved in ROI
30 production, for use in diagnosis and prognosis of abnormal cellular proliferation related to ROI production.

Another object of the present invention is to provide kits useful for the detection, measurement or localization of proteins, or fragments thereof, that are involved in ROI production, for use in diagnosis and prognosis of abnormal cellular proliferation related to ROI production.

5 A further object of the present invention is to use the proteins represented in SEQ ID NO:2 and SEQ ID NO:4, or fragments thereof, to screen for drugs that regulate the cellular levels or activity of proteins in the Nox family.

10 These and other objects, features and advantages of the present invention will become apparent after a review of the following detailed description of the disclosed embodiments and the appended drawings.

BRIEF DESCRIPTION OF THE FIGURES

15 Fig. 1 is a dendrogram indicating the degree of similarity among this family of proteins, and also includes the related plant enzymes.

Fig. 2(a-b) depicts the alignment of the predicted protein sequences of *gp91phox*, Nox 1, Nox 3, Nox 4 and Nox 5.

Fig. 3 is a model consistent with the known features of *gp91phox*.

20 Fig. 4(a-b) depicts tissue expression of Nox 3, Nox 4, and Nox 5 measured by Northern Blot analysis.

Fig. 5 shows RT-PCR measurement of tissue expression of the Nox family of proteins. RT-PCR was carried out using Nox-specific PCR primers as described herein. The number of cycles was 35, except where indicated (number of cycles in parentheses).

25 Fig. 6 (a-b) depicts expression of Nox isoforms in tumor or transformed cell lines; Fig. 6c shows the ratio of expression of *gp91phox*, Nox 4, and Nox 5 compared with glyceraldehyde-3-phosphate dehydrogenase (G3PDH), obtained from real time PCR results.

30 Fig. 7 depicts the creation of a promoter-reporter construct for Nox 1.

DETAILED DESCRIPTION OF THE INVENTION

The present invention solves the problems described above by providing a novel family of nucleotide sequences, and proteins termed Nox proteins, encoded by these nucleotide sequences. The term "Nox" refers to
5 "NADPH-oxidase." These novel proteins are part of a larger related family of proteins that generate ROI, including mox proteins (mox is an abbreviation for mitogenic NADPH oxidase), and Duox proteins, (duox is an abbreviation for dual oxidase). In particular, the present invention provides novel compositions comprising the nucleotide sequences SEQ ID NO:1, SEQ ID NO:3, or SEQ ID
10 NO:5, and fragments thereof. SEQ ID NO:1, or fragments thereof, encode for proteins comprising SEQ ID NO:2 or fragments thereof. SEQ ID NO:3, or fragments thereof, encode for proteins comprising SEQ ID NO:4 or fragments thereof. SEQ ID NO:5 is the promoter region for Nox 1.

The Nox proteins described herein have homology to the gp91phox
15 protein involved in ROI generation, however, the Nox proteins comprise a novel and distinct family of proteins. The Nox proteins included in the present invention have a molecular weight of approximately 65 kDa as determined by reducing gel electrophoresis and are capable of inducing ROI generation in cells. As described in detail below, the Nox proteins of the present invention
20 also function in the regulation of cell growth, and are therefore implicated in diseases involving abnormal cell growth such as cancer. The present invention describes Nox proteins found in humans, however, it is likely that the Nox family of genes/proteins is widely distributed among multicellular organisms.

In addition to the nucleotide sequences described above, the present
25 invention also provides vectors containing these nucleotide sequences and fragments thereof, cells transfected with these vectors which produce the proteins comprising SEQ ID NO:2, SEQ ID NO:4, and fragments thereof, and antibodies to these proteins and fragments thereof. The present invention also provides methods for stimulating cellular proliferation by administering
30 vectors, or cells containing vectors, encoded for production of the proteins comprising SEQ ID NO:2, SEQ ID NO:4, and fragments thereof. The

nucleotides and antibodies of the present invention are useful for the detection, localization and measurement of the nucleic acids encoding for the production of the proteins of the present invention, and also for the detection, localization and measurement of the proteins of the present invention. These nucleotides and antibodies can be combined with other reagents in kits for the purposes of detection, localization and measurement. These kits are useful for diagnosis and prognosis of conditions involving cellular proliferation associated with production of reactive oxygen intermediates.

The present invention solves the problems described above by providing a composition comprising the nucleotide sequence SEQ ID NO:1 and fragments thereof. The present invention also provides a composition comprising the nucleotide sequence SEQ ID NO:3 and fragments thereof. The present invention additionally provides a composition comprising the nucleotide sequence SEQ ID NO: 5 and fragments thereof.

The present invention provides a composition comprising the protein SEQ ID NO:2 encoded by the nucleotide sequence SEQ ID NO:1. The present invention additionally provides a composition comprising the protein SEQ ID NO:4 encoded by the nucleotide sequence SEQ ID NO:3.

The present invention provides a composition comprising the protein SEQ ID NO:2 or fragments thereof, encoded by the nucleotide sequence SEQ ID NO:1 or fragments thereof. The present invention also provides a composition comprising the protein SEQ ID NO:4 or fragments thereof, encoded by the nucleotide sequence SEQ ID NO:3 or fragments thereof.

The present invention also provides vectors containing the nucleotide sequences SEQ ID NO:1, SEQ ID NO:3, or SEQ ID NO:5, and fragments thereof. The present invention also provides cells transfected with these vectors. In addition, the present invention provides cells stably transfected with the nucleotide sequence SEQ ID NO:1 or fragments thereof. The present invention also provides cells stably transfected with the nucleotide sequence SEQ ID NO:3 or fragments thereof.

The present invention provides cells stably transfected with the nucleotide sequence SEQ ID NO:1 or fragments thereof, which produce the protein SEQ ID NO:2 or fragments thereof. In addition, the present invention provides cells stably transfected with the nucleotide sequence SEQ ID NO:3 or
5 fragments thereof which produce the protein SEQ ID NO:4 or fragments thereof.

The present invention provides a method for stimulating growth by administering cells stably transfected with the nucleotide sequence SEQ ID NO:1 which produce the protein SEQ ID NO:2 or fragments thereof. The
10 present invention also provides a method for stimulating growth by administering cells stably transfected with the nucleotide sequence SEQ ID NO:3 or fragments thereof, which produce the protein SEQ ID NO:4 or fragments thereof.

Specifically, the present invention provides a method for stimulating
15 tumor formation by administering cells stably transfected with the nucleotide sequence SEQ ID NO:1 or fragments thereof, which produce the protein SEQ ID NO:2 or fragments thereof. The present invention also provides a method for stimulating tumor formation by administering cells stably transfected with the nucleotide sequence SEQ ID NO:3 or fragments thereof, which produce the
20 protein SEQ ID NO:4 or fragments thereof.

The present invention may also be used to develop anti-sense nucleotide sequences to SEQ ID NO:1, SEQ ID NO:3, or SEQ ID NO:5, or fragments thereof. These anti-sense molecules may be used to interfere with translation of nucleotide sequences, such as SEQ ID NO:1, or SEQ ID NO:3,
25 or fragments thereof, that encode respectively, for proteins such as SEQ ID NO:2, SEQ ID NO:4, or fragments thereof. Administration of these anti-sense molecules, or vectors encoding for these anti-sense molecules, to humans and animals, would interfere with production of proteins such as SEQ ID NO:2, SEQ ID NO:4, or fragments thereof, thereby decreasing production of ROIs
30 and inhibiting cellular proliferation. These methods are useful in producing animal models for use in study of tumor development and vascular growth, and

for study of the efficacy of treatments for affecting tumor and vascular growth *in vivo*.

The present invention also provides a method for high throughput screening of drugs and chemicals which modulate the proliferative activity of the enzymes of the present invention, thereby affecting cell division. Combinatorial chemical libraries may be screened for chemicals which modulate the proliferative activity of these enzymes. Drugs and chemicals may be evaluated based on their ability to modulate the enzymatic activity of the expressed or endogenous proteins, including those represented by SEQ ID NO:2, SEQ ID NO:4, or fragments thereof. Endogenous proteins may be obtained from many different tissues or cells, such as colon cells. Drugs may also be evaluated based on their ability to bind to the expressed or endogenous proteins represented by SEQ ID NO:2, SEQ ID NO:4, or fragments thereof. Enzymatic activity may be NADPH- or NADH-dependent superoxide generation catalyzed by the holoprotein. Enzymatic activity may also be NADPH- or NADH-dependent diaphorase activity catalyzed by either the holoprotein or the flavoprotein domain.

By flavoprotein domain is meant approximately the C-terminal half of the enzymes shown in SEQ ID NO:2, SEQ ID NO:4, or fragments thereof. These proteins and fragments thereof have NADPH-dependent reductase activity towards cytochrome c, nitrobluetetrazolium and other dyes. Expressed proteins or fragments thereof can be used for robotic screens of existing combinatorial chemical libraries. While not wanting to be bound by the following statement, it is believed that the NADPH or NADH binding site and the FAD binding site are useful for evaluating the ability of drugs and other compositions to bind to the Nox enzymes or to modulate their enzymatic activity. The use of the holoprotein or the C-terminal half or end regions are preferred for developing a high throughput drug screen.

The present invention also provides antibodies directed to the proteins SEQ ID NO:2, SEQ ID NO:4, and fragments thereof. The antibodies of the present invention are useful for a variety of purposes including localization,

detection and measurement of the proteins SEQ ID NO:2, SEQ ID NO:4, and fragments thereof. The antibodies may be employed in kits to accomplish these purposes. These antibodies may also be linked to cytotoxic agents for selected killing of cells. The term antibody is meant to include any class of antibody such as IgG, IgM and other classes. The term antibody also includes a completely intact antibody and also fragments thereof, including but not limited to Fab fragments and Fab + Fc fragments.

The present invention also provides the nucleotide sequences SEQ ID NO:1, SEQ ID NO:3, and fragments thereof. These nucleotide sequences are useful for a variety of purposes including localization, detection, and measurement of messenger RNA involved in synthesis of the proteins represented as SEQ ID NO:2, SEQ ID NO:4, and fragments thereof. The present invention also provides the nucleotide sequence for SEQ ID NO:5 and fragments thereof. This nucleotide sequence is useful for a variety of purposes including localization, detection and measurement of messenger RNA involved in synthesis of the Nox family of proteins. These nucleotides may also be used in the construction of labeled probes for the localization, detection, and measurement of nucleic acids such as messenger RNA or alternatively for the isolation of larger nucleotide sequences containing the nucleotide sequences shown in SEQ ID NO:1, SEQ ID NO:3, SEQ ID NO:5, or fragments thereof. These nucleotide sequences may be used to isolate homologous strands from other species using techniques known to one of ordinary skill in the art. These nucleotide sequences may also be used to make probes and complementary strands.

Most particularly, the present invention involves a method for modulation of growth by modifying the proteins represented as SEQ ID NO:2, SEQ ID NO:4, or fragments thereof.

The term "mitogenic regulators" is used herein to mean any molecule that acts to affect cell division.

The term "animal" is used herein to mean humans and non-human animals of both sexes.

The terms "a", "an" and "the" as used herein are defined to mean one or more and include the plural unless the context is inappropriate.

"Proteins", "peptides", "polypeptides" and "oligopeptides" are chains of amino acids (typically L-amino acids) whose alpha carbons are linked through peptide bonds formed by a condensation reaction between the carboxyl group of the alpha carbon of one amino acid and the amino group of the alpha carbon of another amino acid. The terminal amino acid at one end of the chain (*i.e.*, the amino terminal) has a free amino group, while the terminal amino acid at the other end of the chain (*i.e.*, the carboxy terminal) has a free carboxyl group. As such, the term "amino terminus" (abbreviated N-terminus) refers to the free alpha-amino group on the amino acid at the amino terminal of the protein, or to the alpha-amino group (imino group when participating in a peptide bond) of an amino acid at any other location within the protein. Similarly, the term "carboxy terminus" (abbreviated C-terminus) refers to the free carboxyl group on the amino acid at the carboxy terminus of a protein, or to the carboxyl group of an amino acid at any other location within the protein.

Typically, the amino acids making up a protein are numbered in order, starting at the amino terminal and increasing in the direction toward the carboxy terminal of the protein. Thus, when one amino acid is said to "follow" another, that amino acid is positioned closer to the carboxy terminal of the protein than the preceding amino acid.

The term "residue" is used herein to refer to an amino acid (D or L) or an amino acid mimetic that is incorporated into a protein by an amide bond. As such, the amino acid may be a naturally occurring amino acid or, unless otherwise limited, may encompass known analogs of natural amino acids that function in a manner similar to the naturally occurring amino acids (*i.e.*, amino acid mimetics). Moreover, an amide bond mimetic includes peptide backbone modifications well known to those skilled in the art.

Furthermore, one of skill in the art will recognize that, as mentioned above, individual substitutions, deletions or additions which alter, add or delete a single amino acid or a small percentage of amino acids (less than about 20%,

typically less than about 10%, more typically less than about 1%) in an encoded sequence are conservatively modified variations where the alterations result in the substitution of an amino acid with a chemically similar amino acid. Conservative substitution tables providing functionally similar amino acids are well known in the art. The following six groups each contain amino acids that are conservative substitutions for one another:

- 1) Alanine (A), Serine (S), Threonine (T);
- 2) Aspartic acid (D), Glutamic acid (E);
- 10 3) Asparagine (N), Glutamine (Q);
- 4) Arginine (R), Lysine (K);
- 5) Isoleucine (I), Leucine (L), Methionine (M), Valine (V); and
- 6) Phenylalanine (F), Tyrosine (Y), Tryptophan (W).

15 When the peptides are relatively short in length (*i.e.*, less than about 50 amino acids), they are often synthesized using standard chemical peptide synthesis techniques. Solid phase synthesis in which the C-terminal amino acid of the sequence is attached to an insoluble support followed by sequential addition of the remaining amino acids in the sequence is a preferred method
20 for the chemical synthesis of the antigenic epitopes described herein. Techniques for solid phase synthesis are known to those skilled in the art.

Alternatively, the antigenic epitopes described herein are synthesized using recombinant nucleic acid methodology. Generally, this involves creating a nucleic acid sequence that encodes the peptide or protein, placing the nucleic
25 acid in an expression cassette under the control of a particular promoter, expressing the peptide or protein in a host, isolating the expressed peptide or protein and, if required, renaturing the peptide or protein. Techniques sufficient to guide one of skill through such procedures are found in the literature.

30 When several desired protein fragments or peptides are encoded in the nucleotide sequence incorporated into a vector, one of skill in the art will

appreciate that the protein fragments or peptides may be separated by a spacer molecule such as, for example, a peptide, consisting of one or more amino acids. Generally, the spacer will have no specific biological activity other than to join the desired protein fragments or peptides together, or to preserve some
5 minimum distance or other spatial relationship between them. However, the constituent amino acids of the spacer may be selected to influence some property of the molecule such as the folding, net charge, or hydrophobicity. Nucleotide sequences encoding for the production of residues which may be useful in purification of the expressed recombinant protein may be built into
10 the vector. Such sequences are known in the art. For example, a nucleotide sequence encoding for a poly histidine sequence may be added to a vector to facilitate purification of the expressed recombinant protein on a nickel column.

Once expressed, recombinant peptides, polypeptides and proteins can be purified according to standard procedures known to one of ordinary skill in
15 the art, including ammonium sulfate precipitation, affinity columns, column chromatography, gel electrophoresis and the like. Substantially pure compositions of about 50 to 99% homogeneity are preferred, and 80 to 95% or greater homogeneity are most preferred for use as therapeutic agents.

One of skill in the art will recognize that after chemical synthesis,
20 biological expression or purification, the desired proteins, fragments thereof and peptides may possess a conformation substantially different than the native conformations of the proteins, fragments thereof and peptides. In this case, it is often necessary to denature and reduce protein and then to cause the protein to re-fold into the preferred conformation. Methods of reducing and
25 denaturing proteins and inducing re-folding are well known to those of skill in the art.

The genetic constructs of the present invention include coding sequences for different proteins, fragments thereof, and peptides. The genetic constructs also include epitopes or domains chosen to permit purification or
30 detection of the expressed protein. Such epitopes or domains include DNA sequences encoding the glutathione binding domain from glutathione S-

transferase, hexa-histidine, thioredoxin, hemagglutinin antigen, maltose binding protein, and others commonly known to one of skill in the art. The preferred genetic construct includes the nucleotide sequences of SEQ ID NO:1, SEQ ID NO:3, or SEQ ID NO:5, or fragments thereof. It is to be understood
5 that additional or alternative nucleotide sequences may be included in the genetic constructs in order to encode for the following: a) multiple copies of the desired proteins, fragments thereof, or peptides; b) various combinations of the desired proteins, fragments thereof, or peptides; and c) conservative modifications of the desired proteins, fragments thereof, or peptides, and
10 combinations thereof. Preferred proteins include the human Nox 4 protein and human Nox 5 protein shown as SEQ ID NO:2 and SEQ ID NO:4, respectively, and fragments thereof or conservative substitutions thereof.

The nucleotide sequences of the present invention may also be employed to hybridize to nucleic acids such as DNA or RNA nucleotide
15 sequences under high stringency conditions which permit detection, for example, of alternately spliced messages.

The genetic construct is expressed in an expression system such as in NIH 3T3 cells using recombinant sequences in a pcDNA-3 vector (Invitrogen, Carlsbad, CA) to produce a recombinant protein. Preferred expression systems
20 include but are not limited to Cos-7 cells, insect cells using recombinant baculovirus, and yeast. It is to be understood that other expression systems known to one of skill in the art may be used for expression of the genetic constructs of the present invention. The preferred proteins of the present invention are the sequences referred to herein as human Nox 4 and human Nox
25 5 or fragments thereof which have the amino acid sequences set forth in SEQ ID NO:2 and SEQ ID NO:4, respectively, or an amino acid sequence having amino acid substitutions as defined in the definitions that do not significantly alter the function of the recombinant protein in an adverse manner.

Terminology

It should be understood that some of the terminology used to describe the novel Nox proteins contained herein is different from the terminology in PCT/US99/26592, U.S. non-provisional application serial number 09/437,568 and U.S. provisional application serial nos. 60/251,364, 60/249,305, and 60/289,172. The terms mox and nox are equivalents. As described herein, the term "human Nox 4" refers to a protein comprising an amino acid sequence as set forth in SEQ ID NO:2, or fragments or conservative substitutions thereof, and encoded by the nucleotide sequence as set forth in SEQ ID NO:1, or fragments or conservative substitutions thereof. As described herein, the term "human Nox 5" refers to a protein comprising an amino acid sequence as set forth in SEQ ID NO:4, or fragments or conservative substitutions thereof, and encoded by the nucleotide sequence as set forth in SEQ ID NO:3, or fragments or conservative substitutions thereof. The promoter for "human Nox 1" refers to a nucleic acid sequence as set forth in SEQ ID NO:5 or fragments or conservative substitutions thereof.

Construction of the Recombinant Gene

The desired gene is ligated into a transfer vector, such as pcDNA3, and the recombinants are used to transform host cells such as Cos-7 cells. It is to be understood that different transfer vectors, host cells, and transfection methods may be employed as commonly known to one of ordinary skill in the art. Three desired genes for use in transfection are shown in SEQ ID NO:1, SEQ ID NO:3, and SEQ ID NO:5. For example, lipofectamine-mediated transfection and *in vivo* homologous recombination was used to introduce the Nox 4 gene (SEQ ID NO:1) into NIH 3T3 cells.

The synthetic gene is cloned and the recombinant construct containing a Nox gene is produced and grown in confluent monolayer cultures of a Cos-7 cell line. The expressed recombinant protein is then purified, preferably using affinity chromatography techniques, and its purity and specificity determined by known methods.

A variety of expression systems may be employed for expression of the recombinant protein. Such expression methods include, but are not limited to the following: bacterial expression systems, including those utilizing *E. coli* and *Bacillus subtilis*; virus systems; yeast expression systems; cultured insect and mammalian cells; and other expression systems known to one of ordinary skill in the art.

Transfection of Cells

It is to be understood that the vectors of the present invention may be transfected into any desired cell or cell line. Both *in vivo* and *in vitro* transfection of cells are contemplated as part of the present invention. Preferred cells for transfection include but are not limited to the following: fibroblasts (possibly to enhance wound healing and skin formation), granulocytes (possible benefit to increase function in a compromised immune system as seen in AIDS, and aplastic anemia), muscle cells, neuroblasts, stem cells, bone marrow cells, osteoblasts, B lymphocytes, and T lymphocytes.

Cells may be transfected with a variety of methods known to one of ordinary skill in the art and include but are not limited to the following: electroporation, gene gun, calcium phosphate, lipofectamine, and fugene, as well as adenoviral transfection systems.

Host cells transfected with the nucleic acids represented in SEQ ID NO:1, SEQ ID NO:3, or fragments thereof, are used to express the proteins SEQ ID NO:2, SEQ ID NO:4, respectively, or fragments thereof. Host cells transfected with the nucleic acid represented in SEQ ID NO:1, SEQ ID NO:3, or SEQ ID NO:5 or fragments thereof, are also used as screening assays.

These expressed proteins are used to raise antibodies. These antibodies may be used for a variety of applications including but not limited to immunotherapy against cancers expressing one of the Nox proteins, and for detection, localization and measurement of the proteins shown in SEQ ID NO:2, SEQ ID NO:4, or fragments thereof.

Purification and Characterization of the Expressed Protein

The proteins of the present invention can be expressed as a fusion protein with a poly histidine component, such as a hexa histidine, and purified by binding to a metal affinity column using nickel or cobalt affinity matrices.

- 5 The protein can also be expressed as a fusion protein with glutathione S-transferase and purified by affinity chromatography using a glutathione agarose matrix. The protein can also be purified by immunoaffinity chromatography by expressing it as a fusion protein, for example with hemagglutinin antigen. The expressed or naturally occurring protein can also
- 10 be purified by conventional chromatographic and purification methods which include anion and cation exchange chromatography, gel exclusion chromatography, hydroxylapatite chromatography, dye binding chromatography, ammonium sulfate precipitation, precipitation in organic solvents or other techniques commonly known to one of skill in the art.

15

Methods of Assessing Activity of Expressed Proteins

Different methods are available for assessing the activity of the expressed proteins of the present invention, including but not limited to the proteins represented as SEQ ID NO:2, SEQ ID NO:4, conservative

20 substitutions thereof, and fragments thereof.

1. Assays of the holoprotein and fragments thereof for superoxide generation

A. General considerations.

- These assays are useful in assessing efficacy of drugs designed to
- 25 modulate the activity of the enzymes of the present invention. The holoprotein may be expressed in COS-7 cells, NIH 3T3 cells, insect cells (using baculoviral technology) or other cells using methods known to one of skill in the art. Membrane fractions or purified protein are used for the assay. The assay may require or be augmented by other cellular proteins such as p47phox,
- 30 p67phox, and Rac1, as well as potentially other unidentified factors (e.g., kinases or other regulatory proteins).

B. Cytochrome c reduction.

NADPH or NADH is used as the reducing substrate, in a concentration of about 100 μM . Reduction of cytochrome c is monitored spectrophotometrically by the increase in absorbance at 550 nm, assuming an extinction coefficient of 21 $\text{mM}^{-1}\text{cm}^{-1}$. The assay is performed in the absence and presence of about 10 μg superoxide dismutase. The superoxide-dependent reduction is defined as cytochrome c reduction in the absence of superoxide dismutase minus that in the presence of superoxide dismutase (Uhlinger et al. (1991) *J. Biol. Chem.* 266, 20990-20997). Acetylated cytochrome c may also be used, since the reduction of acetylated cytochrome c is thought to be exclusively via superoxide.

C. Nitroblue tetrazolium reduction.

For nitroblue tetrazolium (NBT) reduction, the same general protocol is used, except that NBT is used in place of cytochrome c. In general, about 1 mL of filtered 0.25 % nitrotetrazolium blue (Sigma, St. Louis, MO) is added in Hanks buffer without or with about 600 Units of superoxide dismutase (Sigma) and samples are incubated at approximately 37°C. The oxidized NBT is clear, while the reduced NBT is blue and insoluble. The insoluble product is collected by centrifugation, and the pellet is re-suspended in about 1 mL of pyridine (Sigma) and heated for about 10 minutes at 100°C to solubilize the reduced NBT. The concentration of reduced NBT is determined by measuring the absorbance at 510 nm, using an extinction coefficient of 11,000 $\text{M}^{-1}\text{cm}^{-1}$. Untreated wells are used to determine cell number.

D. Luminescence.

Superoxide generation may also be monitored with a chemiluminescence detection system utilizing lucigenin (bis-N-methylacridinium nitrate, Sigma, St. Louis, MO). The sample is mixed with about 100 μM NADPH (Sigma, St. Louis, MO) and 10 μM lucigenin (Sigma, St. Louis, MO) in a volume of about 150 μL Hanks solution. Luminescence is

monitored in a 96-well plate using a LumiCounter (Packard, Downers Grove, IL) for 0.5 second per reading at approximately 1 minute intervals for a total of about 5 minutes; the highest stable value in each data set is used for comparisons. As above, superoxide dismutase is added to some samples to
5 prove that the luminescence arises from superoxide. A buffer blank is subtracted from each reading (Ushio-Fukai et al. (1996) *J. Biol. Chem.* 271, 23317-23321).

E. Assays in intact cells.

10 Assays for superoxide generation may be performed using intact cells, for example, the Nox-transfected NIH 3T3 cells. In principle, any of the above assays can be used to evaluate superoxide generation using intact cells, for example, the Nox-transfected NIH 3T3 cells. NBT reduction is a preferred assay method.

15

2. Assays of truncated proteins comprised of approximately the C-terminal 265 amino acid residues

While not wanting to be bound by the following statement, the truncated protein comprised of approximately the C-terminal 265 amino acid
20 residues is not expected to generate superoxide, and therefore, superoxide dismutase is not added in assays of the truncated protein. Basically, a similar assay is established and the superoxide-independent reduction of NBT, cytochrome c, dichlorophenolindophenol, ferricyanide, or another redox-active dye is examined.

25

Nucleotides and Nucleic Acid Probes

The nucleotide sequences SEQ ID NO:1, SEQ ID NO:3, SEQ ID NO:5, as well as fragments thereof and PCR primers therefore, may be used, respectively, for localization, detection and measurement of nucleic acids
30 related to SEQ ID NO:1, SEQ ID NO:3, SEQ ID NO:5, as well as fragments thereof. The nucleotide sequences SEQ ID NO:1 and SEQ ID NO:3 are also

called the human Nox 4 gene and the human Nox 5 gene respectively, in this application. The nucleotide sequence SEQ ID NO:5 is called the Nox 1 promoter sequence in this application.

5 The nucleotide sequences SEQ ID NO:1, SEQ ID NO:3, SEQ ID NO:5, as well as fragments and conservative substitutions thereof, may be used to create probes to isolate larger nucleotide sequences containing the nucleotide sequences SEQ ID NO:1, SEQ ID NO:3, and SEQ ID NO:5, respectively. The nucleotide sequences SEQ ID NO:1, SEQ ID NO:3, and SEQ ID NO:5 as well as fragments thereof and conservative substitutions thereof, may also be used
10 to create probes to identify and isolate Nox proteins in other species.

The nucleic acids described herein include messenger RNA coding for production of SEQ ID NO:2, SEQ ID NO:4, and fragments and conservative substitutions thereof. Such nucleic acids include but are not limited to cDNA probes. These probes may be labeled in a variety of ways known to one of
15 ordinary skill in the art. Such methods include but are not limited to isotopic and non-isotopic labeling. These probes may be used for *in situ* hybridization for localization of nucleic acids such as mRNA encoding for SEQ ID NO:2, SEQ ID NO:4, and fragments and conservative substitutions thereof. Localization may be performed using *in situ* hybridization at both
20 ultrastructural and light microscopic levels of resolution using techniques known to one of ordinary skill in the art.

These probes may also be employed to detect and quantitate nucleic acids and mRNA levels using techniques known to one of ordinary skill in the art including but not limited to solution hybridization.

25

Administration of the Nox Proteins of the Present Invention

The proteins represented by SEQ ID NO:2, or SEQ ID NO:4, or fragments or conservative substitutions thereof, are combined with a pharmaceutically acceptable carrier or vehicle to produce a pharmaceutical
30 composition and are administered to animals. Such administration may occur

for stimulation of growth or cellular proliferation. Administration may also occur for generation of antibodies.

The terms "pharmaceutically acceptable carrier or pharmaceutically acceptable vehicle" are used herein to mean any liquid including but not
5 limited to water or saline, oil, gel, salve, solvent, diluent, fluid ointment base, liposome, micelle, giant micelle, and the like, which is suitable for use in contact with living animal or human tissue without causing adverse physiological responses, and which does not interact with the other components of the composition in a deleterious manner.

10 The pharmaceutical compositions may conveniently be presented in unit dosage form and may be prepared by conventional pharmaceutical techniques. Such techniques include the step of bringing into association the active ingredient and the pharmaceutical carrier(s) or excipient(s). In general, the formulations are prepared by uniformly and intimately bringing into
15 association the active ingredient with liquid carriers.

Formulations suitable for parenteral administration include aqueous and non-aqueous sterile injection solutions which may contain anti-oxidants, buffers, bacteriostats and solutes which render the formulation isotonic with the blood of the intended recipient; and aqueous and non-aqueous sterile
20 suspensions which may include suspending agents and thickening agents. The formulations may be presented in unit-dose or multi-dose containers, for example, sealed ampules and vials, and may be stored in a freeze-dried (lyophilized) condition requiring only the addition of the sterile liquid carrier, for example, water for injections, immediately prior to use. Extemporaneous
25 injection solutions and suspensions may be prepared from sterile powders, granules and tablets commonly used by one of ordinary skill in the art.

Preferred unit dosage formulations are those containing a dose or unit, or an appropriate fraction thereof, of the administered ingredient. It should be understood that in addition to the ingredients, particularly mentioned above,
30 the formulations of the present invention may include other agents commonly used by one of ordinary skill in the art.

The pharmaceutical composition may be administered through different routes, such as oral, including buccal and sublingual, rectal, parenteral, aerosol, nasal, intramuscular, subcutaneous, intradermal, and topical. The pharmaceutical composition of the present invention may be administered in
5 different forms, including but not limited to solutions, emulsions and suspensions, microspheres, particles, microparticles, nanoparticles, and liposomes.

The pharmaceutical composition may be stored at temperatures of from about 4°C to -100°C. The pharmaceutical composition may also be stored in a
10 lyophilized state at different temperatures including room temperature. The pharmaceutical composition may be sterilized through conventional means known to one of ordinary skill in the art. Such means include, but are not limited to filtration, radiation and heat. The pharmaceutical composition of the present invention may also be combined with bacteriostatic agents, such as
15 thimerosal, to inhibit bacterial growth.

Administration may also occur for the production of polyclonal antibodies using methods known to one of ordinary skill in the art. The preferred animals for antibody production are rabbits and mice. Other animals may be employed for immunization with these proteins or fragments thereof.
20 Such animals include, but are not limited to the following; sheep, horses, pigs, donkeys, cows, monkeys and rodents such as guinea pigs and rats. It is expected that from about 1 to 7 dosages may be required per immunization regimen. Initial injections may range from about 0.1 µg to 1 mg, with a preferred range of about 1 µg to 800 µg, and a more preferred range of from
25 approximately 25 µg to 500 µg. Booster injections may range from 0.1 µg to 1 mg, with a preferred range of approximately 1 µg to 800 µg, and a more preferred range of about 10 µg to 500 µg.

The volume of administration will vary depending on the route of administration and the size of the recipient. For example, intramuscular
30 injections may range from about 0.1 ml to 1.0 ml.

Adjuvants

A variety of adjuvants known to one of ordinary skill in the art may be administered in conjunction with the protein in the pharmaceutical composition for generation of antibodies. Such adjuvants include, but are not
5 limited to the following: polymers, co-polymers such as polyoxyethylene-polyoxypropylene copolymers, including block co-polymers; polymer P1005; Freund's complete adjuvant (for animals); Freund's incomplete adjuvant; sorbitan monooleate; squalene; CRL-8300 adjuvant; alum; QS 21, muramyl dipeptide; trehalose; bacterial extracts, including mycobacterial extracts;
10 detoxified endotoxins; membrane lipids; or combinations thereof.

Monoclonal antibodies can be produced using hybridoma technology in accordance with methods well known to those skilled in the art. The antibodies are useful as research or diagnostic reagents or can be used for passive immunization. The composition may optionally contain an adjuvant.

15 The polyclonal and monoclonal antibodies useful as research or diagnostic reagents may be employed for detection and measurement of SEQ ID NO:2, SEQ ID NO:4, and fragments or conservative substitutions thereof. Such antibodies may be used to detect these proteins in a biological sample, including but not limited to samples such as cells, cellular extracts, tissues,
20 tissue extracts, biopsies, tumors, and biological fluids. Such detection capability is useful for detection of disease related to these proteins to facilitate diagnosis and prognosis and to suggest possible treatment alternatives.

Detection may be achieved through the use of immunocytochemistry, ELISA, radioimmunoassay or other assays as commonly known to one of
25 ordinary skill in the art. The Nox 4 and Nox 5 proteins, or fragments or conservative substitutions thereof, may be labeled through commonly known approaches, including but not limited to the following: radiolabeling, dyes, magnetic particles, biotin-avidin, fluorescent molecules, chemiluminescent molecules and systems, ferritin, colloidal gold, and other methods known to
30 one of skill in the art of labeling proteins.

Administration of Antibodies

The antibodies directed to the proteins shown as SEQ ID NO:2, SEQ ID NO:4, or directed to fragments or conservative substitutions thereof, may also be administered directly to humans and animals in a passive immunization paradigm. Antibodies directed to extracellular portions of SEQ ID NO:2, SEQ ID NO:4, or fragments thereof bind to these extracellular epitopes. Attachment of labels to these antibodies facilitates localization and visualization of sites of binding. Attachment of molecules such as ricin or other cytotoxins to these antibodies helps to selectively damage or kill cells expressing SEQ ID NO:2, SEQ ID NO:4, or fragments thereof.

Kits

The present invention includes kits useful with the antibodies, nucleic acid probes, labeled antibodies, labeled proteins or fragments thereof for detection, localization and measurement of SEQ ID NO:1, SEQ ID NO:2, SEQ ID NO:3, SEQ ID NO:4, SEQ ID NO:5 or combinations thereof and fragments or conservative substitutions thereof. The diagnostic kits may also measure or detect the relative expression of the Nox proteins described herein (i.e. human Nox 4 and/or human Nox 5)

Kits may be used for immunocytochemistry, *in situ* hybridization, solution hybridization, radioimmunoassay, ELISA, Western blots, quantitative PCR, and other assays for the detection, localization and measurement of these nucleic acids, proteins or fragments thereof using techniques known to one of skill in the art.

The nucleotide sequences shown in SEQ ID NO:1, SEQ ID NO:3, SEQ ID NO:5, or fragments thereof, may also be used under high stringency conditions to detect alternately spliced messages related to SEQ ID NO:1, SEQ ID NO:3, SEQ ID NO:5, or fragments thereof, respectively.

Fragments of SEQ ID NO:1, SEQ ID NO:3, SEQ ID NO:5, containing the relevant hybridizing sequence can be synthesized onto the surface of a chip array. RNA samples, e.g., from tumors, are then fluorescently tagged and

hybridized onto the chip for detection. This approach may be used
diagnostically to characterize tumor types and to tailor treatments and/or
provide prognostic information. Such prognostic information may have
predictive value concerning disease progression and life span, and may also
5 affect choice of therapy.

The other present invention is further illustrated by the following
examples, which are not to be construed in any way as imposing limitations
upon the scope thereof. On the contrary, it is to be clearly understood that
resort may be had to various other embodiments, modifications, and
10 equivalents thereof, which, after reading the description herein, may suggest
themselves to those skilled in the art without departing from the spirit of the
present invention.

EXAMPLE 1

15 *Sequence Analysis and Cloning of the Human Nox 4 cDNA (SEQ ID NO:1)*
Encoding for Production of the Human Nox 4 Protein (SEQ ID NO:2)

Using Nox 3 (SEQ ID NO:6) as a query sequence, a 789 base pair
sequenced portion of expressed sequence tag (EST) GenBank Accession
number AI742260) and a 408 base EST clone (GenBank No. AI885681, a
20 clone exhibiting a 26% identity to the cDNA sequence corresponding to amino
acid residues 433-560 of Nox 3, and a second clone showing 36% identity to
the cDNA sequence corresponding to amino acid residues 5-48 of Nox 3 were
discovered. This homologue was cloned using two PCR primers based on the
two EST sequences: (SEQ ID NO:7, 5'-
25 CAACGAAGGGGTAAACACCTCTGC-3'; and SEQ ID NO:8, 5'-
CACAGCTGATTGATTCCGCTGAG-3'). PCR was carried out using human
fetal kidney marathon-ready cDNA (Clontech, Palo Alto, CA), and the 0.85 kb
product was sequenced. Based on the sequencing results, 5'- and 3'- RACE
using the same library using the following primers: 5'-RACE: SEQ ID NO:9,
30 5'-TAAGCCAAGAGTGTTTCGGCACATG-3'; SEQ ID NO:10, 5'-
TACTCTGGCCCTTGGTTATACAGCA-3'(for nested PCR); 3'-RACE: SEQ

ID NO:11, 5'-TCCATTACCTCACAATGTGT-3'; SEQ ID NO:12, 5'-CTCAGCGGAATCAATCAGCTGTG-3'(for nested PCR) was then carried out. PCR parameters were 95°C for 30s, 62°C or 65°C for 20s, 72°C for 45s, 25-35 cycles as indicated after denaturing for 1 min 30s at 95°C. PCR products were purified with a QIAquick PCR purification kit or a gel purification kit (QIAGEN, Valencia, CA). The positive PCR bands were sequenced by ABI 377 automatic sequencing. Primers were designed to subclone the full-length cDNA and the correct sequence was confirmed by automated sequencing.

10 Secretion signal sequences were predicted according to web-based SMART program (version 3.1) at EMBL (<http://www.smart.embl-heidelberg.de/smart/>). Prediction of open reading frames (ORF) was carried out using the EditSeq program (DNASTAR), and phylogenetic analyses and multiple sequence alignment were carried out using the clustal method using 15 the Megalign program (DNASTAR). Transmembrane alpha helices were predicted using the TMHMM algorithms through the Center for Biological Sequence Analysis (<http://genome.cbs.dtu.dk/services/TMHMM/>).

Total RNA was extracted from cell lines with Trizol (Life Technologies, Gaithersburg, MD) based on the manufacturer's protocol or 20 according to (Ishii et al., 1999) for glioma cell lines. RNAs were reverse transcribed into first-strand cDNA with Superscript II (Life Technologies, Gaithersburg, MD) using oligo-dT according on the method provided by the manufacturer.

Table 4 shows the basic features of the cDNA and the predicted 25 proteins. Like the proteins encoded by *gp91phox* (a.k.a., Nox 2 SEQ ID NO:13) and Nox 1 (SEQ ID NO:14), the new sequences encode predicted proteins of around 65 kDa, and message sizes are similar in length (2.0 - 2.2 kb). Nox 4 also has 59 amino acids which are strongly basic, 45 amino acids which are strongly acidic, 212 hydrophobic amino acids, 171 polar amino 30 acids, an isoelectric point of 8.695 and a charge of 16.549 at a pH of 7.0. Nox 4 also shows 21 - 59% identity with *gp91phox* and with Nox 1. Nox 1,

gp91*phox*, Nox 3 and Nox 4 cluster within a sub-family that is similar to gp91*phox*. The alignment of the predicted protein sequence of Nox 4 is shown in Fig. 2. The molecules are roughly divided into two large domains: an N-terminal cluster of hydrophobic membrane-spanning sequences, and a C-terminal flavoprotein domain. The latter shows weak homology with a number of FAD binding proteins including cytochrome P-450 reductase and ferredoxin-NADP oxidoreductase (Rotrosen et al., 1992; Segal et al., 1992). Within the flavoprotein domain are two segments (indicated in Fig. 2(a-b)) that show homology with known FAD binding sites in other flavoproteins, and four segments closer to the C-terminus that are homologous to documented pyridine nucleotide binding sites in other proteins. The first of these includes the G-X-G-X-X-P canonical sequence that characterizes pyridine nucleotide binding sites. In all Nox forms, this sequence is followed by an F, which is typical of NADPH- rather than NADH-specific enzymes.

Nox 4 contains the predicted transmembrane alpha helix near the extreme N-terminus (light hashed box in Fig. 2). However, this region is also strongly predicted to be a signal peptide sequence in these forms. Predicted proteolytic cleavage sites for each isoform are indicated by the arrows, and cleavage at these positions would lead to a loss of the first putative transmembrane sequence. Five additional transmembrane regions are also predicted in this protein. The most C-terminal of these is weakly predicted in Nox 1, gp91*phox*, Nox 3 and Nox 4 and is entirely missed by some prediction algorithms. It is necessary to include this transmembrane region in order to generate a model (Fig. 3) which is consistent with known features of gp91*phox*, particularly a cytosolic facing location of the flavoprotein domain. In this model, known N-linked glycosylation sites in gp91*phox* are correctly localized to extracellular loops (although these sites are not conserved in other isoforms). In addition, a polybasic loop of gp91*phox* that binds to the cytosolic regulatory protein p47*phox* (Biberstine-Kinkade et al., 1999) is localized on the cytosolic face. In general, extracellular loops tend to be highly

variable in length and sequence, whereas the transmembrane helices and intracellular loops tend to be more conserved in sequence and length (Fig. 2).

Within the N-terminus are five absolutely conserved histidines (Fig. 2), that are also conserved in all other members of the Nox family of enzymes.

5 gp91phox contains two heme groups, the irons of which are each ligated by two histidyl nitrogens (Isogai et al., 1993), and these are thought to reside within the N-terminus (Yu et al., 1998). An additional conserved histidine lies within the FAD-binding region and is therefore not a candidate for heme ligation. Thus, four of the five histidines within the N-terminus probably
10 participate in heme ligation, providing part of the binding sites for two heme groups, as indicated in Fig. 3.

TABLE 4

Molecular Features of Nox 3, Nox 4, and Nox 5 cDNA

	Nox 3	Nox 4	Nox 5
cDNA length (bp)	2044	2232	2199
Predicted number of amino acids	568	578	565
Predicted protein Mw (kDa)	64.9	66.9	64.7
pI of protein	8	8.7	9.7
Kozek sequence	ATCATGA or ATGATGG	GGCATGG	GTCATGG
Identity to gp91phox	58%	37%	27%
Identity to NoxI	55%	35%	29%
GenBank accession No.	AF190122	AF254621	AF317889

15

EXAMPLE 2

Tissue Expression of Nox 4 mRNA

The predominant Nox 4 2.4 kb message, which corresponds to the size expected for the full-length Nox 4 transcript, is highly expressed in adult as
20 well as fetal kidney (Fig. 4A). An additional weak Nox 4 band was also

detected at 4.5 kilobases (kb) in fetal and adult kidney (Fig. 4A). It is particularly expressed at the site of erythropoietin production in the kidney. RT-PCR confirmed kidney expression and also revealed expression of Nox 4 in all fetal tissues tested as well as in several adult tissues including pancreas, placenta, ovary, testis and skeletal muscle.

EXAMPLE 3

Sequence Analysis and Cloning of the cDNA for Human Nox 5

The Blast search using Nox 3 (SEQ ID NO:6) as a query sequence also identified homology with two unfinished genomic clones, GenBank No. AC027088 and AC026512, respectively. These clones exhibit 46 to 50% identity to Nox 3 within three exons. 5'- and 3'- RACE were carried out using human fetal kidney marathon-ready cDNA (Clontech, Palo Alto, CA), using the following four primers which were designed based on the genomic sequence: SEQ ID NO:15, 5'-CTCATTGTCACACTCCTCGACAGC-3'; SEQ ID NO:16, 5'-TGGGTCTGATGCCTTGAAGGACTC-3' (for nested PCR); 3'-RACE: SEQ ID NO:17, 5'-ATCAAGCGGCCCCCTTTTTCAC-3'; SEQ ID NO:18, 5'-CTGAACATCCCCACCATGCTCGC-3' (for nested PCR). PCR parameters were 95°C for 30s, 62°C or 65°C for 20s, 72°C for 45s, 25-35 cycles as indicated after denaturing for 1.5 minutes at 95°C. PCR products were purified with a QIAquick PCR purification kit or a gel purification kit (QIAGEN, Valencia, CA). Primers were designed to subclone the full-length cDNA and the correct sequence was confirmed by ABI 3777 automated sequencing.

Secretion signal sequences were predicted according to web-based SMART program (version 3.1) at EMBL (<http://www.smart.embl-heidelberg.de/smart/>). Prediction of open reading frames (ORF) was carried out using the EditSeq program (DNASTAR), and phylogenetic analyses and multiple sequence alignment were carried out using the clustal method using the Megalign program (DNASTAR). Transmembrane alpha helices were

predicted using the TMHMM algorithms through the Center for Biological Sequence Analysis (<http://genome.cbs.dtu.dk/services/TMHMM/>).

Total RNA was extracted from cell lines with Trizol (Life Technologies, Gaithersburg, MD) based on the manufacturer's protocol or according to Ishii *et al.*, (1999) for glioma cell lines. RNAs were reverse transcribed into first-strand cDNA with Superscript II (Life Technologies, Gaithersburg, MD) using oligo-dT according on the method provided by the manufacturer.

Table 4 shows the basic features of the cDNA and the predicted proteins. Like the proteins encoded by *gp91phox* (SEQ ID NO:13) and Nox 1 (SEQ ID NO:14), the new sequences for Nox 4 and Nox 5 encode predicted proteins of around 65 kDa, and message sizes are similar in length (2.0 - 2.2 kb). Nox 3, Nox 4 and Nox 5 show 21 - 59% identity with *gp91phox*. Nox 5 forms a unique group, of which it is the only member identified to date, and which is highly divergent from other members of the family. Based on its position in the family tree, Nox 5 may represent the gene which is closest to the primordial Nox.

The alignment of the predicted protein sequences of *gp91phox*, Nox 1, Nox 3, Nox 4 and Nox 5 is shown in Fig. 2. The molecules are roughly divided into two large domains: an N-terminal cluster of hydrophobic membrane-spanning sequences, and a C-terminal flavoprotein domain. The latter shows weak homology with a number of FAD binding proteins including cytochrome P-450 reductase and ferredoxin-NADP oxidoreductase (Rotrosen *et al.*, 1992; Segal *et al.*, 1992). Within the flavoprotein domain are two segments (indicated in Fig. 2) that show homology with known FAD binding sites in other flavoproteins, and four segments nearer the C-terminus that are homologous to documented pyridine nucleotide binding sites in other proteins. The first of these includes the G-X-G-X-X-P canonical sequence that characterizes pyridine nucleotide binding sites. In all Nox forms, this sequence is followed by an F, which is typical of NADPH- rather than NADH-specific enzymes.

While the N-terminal half of Nox 1, Nox 3, Nox 4, and Nox 5 are all hydrophobic, Nox 5 differs from the others somewhat in the details of predicted transmembrane alpha helices, as illustrated in Fig. 2. Nox 5 does not contain an N-terminal predicted signal peptide, but does contain a predicted transmembrane alpha helix (first hashed box, Nox 5 sequence in Fig. 2). According to the prediction algorithm, the extreme N-terminus of Nox 5 is located on the inside of the membrane, on the same side as the flavoprotein domain. Five additional transmembrane regions are also predicted in these proteins. The most C-terminal of these is strongly predicted in Nox 5. It is necessary to include this transmembrane region in order to generate a model (Fig. 3) which is consistent with known features of *gp91phox*, particularly a cytosolic facing location of the flavoprotein domain. In this model, known N-linked glycosylation sites in *gp91phox* are correctly localized to extracellular loops (although these sites are not conserved in other isoforms). In addition, a polybasic loop of *gp91phox* that binds to the cytosolic regulatory protein *p47phox* (Biberstine-Kinkade et al., 1999) is localized on the cytosolic face. In general, extracellular loops tend to be highly variable in length and sequence, whereas the transmembrane helices and intracellular loops tend to be more conserved in sequence and length (Fig. 2).

Within the N-terminus are five absolutely conserved histidines (Fig. 2), that are also conserved in all other members of the Nox family of enzymes (data not shown). *gp91phox* contains two heme groups, the irons of which are each ligated by two histidyl nitrogens (Isogai et al., 1993), and these are thought to reside within the N-terminus (Yu et al., 1998). An additional conserved histidine lies within the FAD-binding region and is therefore not a candidate for heme ligation. Thus, four of the five histidines within the N-terminus probably participate in heme ligation, providing part of the binding sites for two heme groups, as indicated in Fig. 3.

Additionally, located at the extreme N-terminus on the cytosolic side of the membrane of Nox 5 is a highly cationic proline-rich sequence (the Pro-Arg-Rich sequence indicated in Fig. 2 and Fig. 3). This region is thought to

serve as a binding sequence for Src-Homology 3 (SH3) domains in another protein. SH3 domains are known to recognize inter- or intra-molecular proline-rich sequences. This is similar to p22*phox*, a membrane-associated subunit that associates with gp91*phox*, and contains a C-terminal, proline-rich
5 sequence (Parkos et al., 1988) that serves as a binding site for a SH3 domain in p47*phox*, one of the cytosolic subunits that regulates the activity of gp91*phox*. Although not wanting to be bound by the following statement, it is possible that the proline-rich sequence in Nox 5 serves as an internal p22*phox*, allowing interaction with cytosolic regulatory proteins.

10

EXAMPLE 4

Tissue Expression of Nox 5 mRNA

Northern blots probed for Nox 5 using a 3'-portion of the coding region (Fig. 4A) revealed the presence of a 2.2 kb band corresponding in size to the
15 full-length Nox 5 transcript in all fetal tissues tested. This species was also seen in low amounts in adult spleen and testis, along with larger transcripts at 2.6 kb and 6 kb. A probe using a portion of the 3' untranslated region also revealed the presence of the same 2.6 kb and 6 kb bands (Fig. 4B). Thus, these larger bands are larger transcripts derived from the same gene. RT-PCR
20 confirmed expression of Nox 5 in testis and spleen, and also revealed weak expression in ovary, placenta, and pancreas (Fig. 5).

EXAMPLE 5

Real Time RT-PCR of Nox 4 and Nox 5.

25 G3PDH was used as a control. The G3PDH PCR product was purified using a QIAquick PCR purification kit (QIAGEN, Valencia, CA) and quantified using absorbance at 260 nm using a BECKMAN DU640B spectrophotometer. The standard curve for G3PDH was constructed using 10-fold serial dilutions of a known concentration of G3PDH PCR product in
30 distilled water. Real time PCR amplification was carried out using a LightCycler (Roche Molecular Biochemicals, Indianapolis, IN) in a PCR

reaction containing 0.2 μ M of each primer, 1: 84,000 SYBR Green I (Molecular Probes, Eugene, OR) and Advantage 2 Polymerase Mix (Clontech, Palo Alto, CA). Amplification was carried out for 36 cycles of denaturation (95°C, 0s, ramp rate 20°/s), annealing (65°C, 5s, ramp rate 20/s) and extension (72°C, 30s ramp rate 20°C/s). Fluorescence was monitored at the end of each extension phase. Quantitation and melting curve were analyzed with the LightCycler software. RT-PCR confirmed kidney expression and also revealed expression of Nox 4 in all fetal tissues tested as well as in several adult tissues including pancreas, placenta, ovary, testis and skeletal muscle. (See Fig. 5) The ratio of copies of unknown to standard G3PDH was then calculated and is reported in Fig. 6C. RT-PCR also confirmed expression of Nox 5 in testis and spleen, and revealed weak expression in ovary, placenta, and pancreas (Fig. 5). The data indicate that expression patterns of Nox family members are tissue specific, and do not correspond to the expression of gp91phox.

EXAMPLE 6

Northern Blotting of Nox 4 and Nox 5

The Human Fetal and Adult Multiple Tissue Northern Blot (Clontech, Palo Alto, CA) was hybridized with ³²P- random primer-labeled Nox 4, or Nox 5 probe according to the manufacturer's instructions. The probes were prepared by PCR with primers for Nox 4: SEQ ID NO:7 and SEQ ID NO:8; and primers for Nox 5: SEQ ID NO:19, 5'-CTGAACATCCCCACCATTTGCTCGC-3' and SEQ ID NO: 20, 5'-GAAGCCGAACTTCTCACAATGGCC-3'. The PCR products represent coding sequences corresponding to amino acids 11 - 294 (Nox 4), or 278 - 557 (Nox 5). Because the Nox 5 transcript sizes differ between fetal and adult northern blots, a 420bp PCR product of the Nox 5 3'-untranslated region amplified by primers (SEQ ID NO: 21 5'-CCTCACCTCTCCAAGCTCTGCCCC-3' and SEQ ID NO: 22 5'-

TTGAACAATTTTATAAGATGCCGG-3') was also used to hybridize Northern Blots.

The predominant Nox 4 2.4 kb message, which corresponds to the size expected for the full-length Nox 4 transcript, is highly expressed in adult as well as fetal kidney (Fig. 4A), confirming recent reports (Kikuchi et al., 2000; Geiszt et al., 2000; Shiose et al., 2000). An additional weak Nox 4 band was also detected at 4.5 kilobases (kb) in fetal and adult kidney (Fig. 4A). Northern blots probed for Nox 5 (Fig. 4A) revealed the presence of a 2.2 kb band corresponding in size to the full-length Nox 5 transcript in all fetal tissues tested. This species was also seen in low amounts in adult spleen and testis, along with larger transcripts at 2.6 kb and 6 kb. A probe using a portion of the 3' untranslated region also revealed the presence of the same 2.6 kb and 6 kb bands (Fig. 4B). Thus, these larger bands are larger transcripts derived from the same gene.

15

EXAMPLE 7

Transfection of NIH3T3 Cells with SEQ ID NO:1 or SEQ ID NO:3

The nucleotide sequence SEQ ID NO:1 or SEQ ID NO:3 encoding for production of the Nox 4 protein (SEQ ID NO:2) or the Nox 5 protein (SEQ ID NO:4), respectively, is subcloned into the *NotI* site of the pEF-PAC vector (obtained from Mary Dinauer, Indiana University Medical School, Indianapolis, IN) which has a puromycin resistance gene. Transfection is carried out as described in Sambrook et al., Molecular Cloning, A Laboratory Manual, Volumes 1-3, 2nd edition, Cold Spring Harbor Laboratory Press, N.Y., 1989. The SEQ ID NO:1 in pEF-PAC and the empty vector are separately transfected into NIH 3T3 cells using Fugene 6 (Boehringer Mannheim).

10^5 to 10^3 cells stably transfected separately with human Nox 4 gene SEQ ID NO:1, with human Nox 5 gene SEQ ID NO:3, and with empty vector are prepared in 0.3% warm (40°C) agar solution containing DMEM and 10% calf serum. Cells are distributed onto a hardened 0.6% agar plate prepared

30

with DMEM and 10% calf serum. After three weeks in culture (37°C, 5% CO₂) colony formation is observed by microscopy.

About 2 x 10⁶ cells maintained in DMEM containing 10% calf serum are transfected with 10 µg of DNA. After 2 days, cells are split and
5 selected in the same medium containing 1mg/ml puromycin. Colonies that survive in selection media for 10 to 14 days are subcultured continuously in the presence of puromycin.

Cells which are stably transfected with the empty vector and cultured in soft agar for 3 weeks as above do not display anchorage independent
10 growth. In contrast, NIH 3T3 cells which are stably transfected with the Nox 4 (SEQ ID NO:1) or with the Nox 5 gene (SEQ ID NO:3) cultured for 3 weeks in soft agar demonstrate anchorage independent growth of colonies. Transfected cells exhibit a transformed-like morphology, similar to that seen with (V12)Ras-transfected cells, characterized by long spindle-like cells.

15

EXAMPLE 8

Expression of Nox 4 (SEQ ID NO:1) or Nox 5 (SEQ ID NO:3) in Transfected NIH3T3 Cells

To verify the expression of Nox 4 mRNA or Nox 5 mRNA after
20 transfection, RT-PCR and Northern blotting are performed. Total RNAs are prepared from 10⁶ cells using the High Pure RNA Isolation Kit (Boeringer Mannheim) or Rneasy kit (Qiagen). cDNAs for each colony are prepared from 1-2 µg of total RNA using Advantage RT-PCR Kit (ClonTech). PCR amplification is performed using primers, SEQ ID NO: 23 and SEQ ID NO:24.
25 For Northern blotting, 10-20 µg of total RNA is separated on a 1% agarose formaldehyde gel and transferred to a nylon filter. After ultraviolet (UV) cross-linking, filters are used for Northern blotting assay as described in Example 6. Colonies expressing large amounts of Nox 4 mRNA or Nox 5 mRNA are chosen for further analysis.

30

EXAMPLE 9

NADPH-Dependent Superoxide Generation Assay

In one embodiment of the present invention, NIH 3T3 cells stably transfected with the human Nox 4 gene (SEQ ID NO:1) or human Nox 5 gene (SEQ ID NO:3) are analyzed for superoxide generation using the lucigenin (Bis-N-methylacridinium luminescence assay (Sigma, St. Louis, MO, Li et al. (1998) J. Biol. Chem. 273, 2015-2023). Cells are washed with cold HANKS' solution and homogenized on ice in HANKS' buffer containing 15% sucrose using a Dounce homogenizer. Cell lysates are frozen immediately in a dry ice/ethanol bath. For the assay, 30 µg of cell lysate is mixed with 200 µM NADPH and 500 µM lucigenin. Luminescence is monitored using a LumiCounter (Packard) at three successive one minute intervals and the highest value was used for comparison. Protein concentration is determined by the Bradford method.

Superoxide generation is monitored in lysates from some of the stably transfected cell lines and is compared with superoxide generation by the untransfected NIH 3T3 cell lysates. The luminescent signal is inhibited by superoxide dismutase and the general flavoprotein inhibitor diphenylene iodonium, but is unaffected by added recombinant human p47phox, p67phox and Rac1(GTP-γS), which are essential cytosolic factors for the phagocyte respiratory-burst oxidase.

In an alternate and preferred embodiment of the present invention, cells that are stably transfected with Nox 4 (YA28), Nox 5 (YA28) or with empty vector (NEF2) are grown in 10 cm tissue culture plates in medium containing DMEM, 10% calf serum, 100 units/ml penicillin, 100 µg/ml streptomycin, and 1 µg/ml puromycin to approximately 80% confluency. Cells (five tissue culture plates of each cell type) are washed briefly with 5 ml phosphate buffered saline (PBS) then dissociated from the plates with PBS containing 5 mM EDTA. Cells are pelleted by centrifuging briefly at 1000 x g.

To permeabilize the cells, freeze thaw lysis is carried out and this is followed by passage of the cell material through a small bore needle. The supernatant is removed and the cells are frozen on dry ice for 15 minutes.

After cells are thawed, 200 μ l lysis buffer (HANKS' Buffered Salt Solution - HBBS) containing a mixture of protease inhibitors from Sigma (Catalog no. P2714) is added. Cells on ice are passed through an 18 gauge needle 10 times and 200 μ l of HBSS buffer containing 34% sucrose was added to yield a final
5 concentration of 17% sucrose. Sucrose appeared to enhance stability upon storage. The combination of freeze-thawing and passage through a needle results in lysis of essentially all of the cells, and this material is referred to as the cell lysate.

The cell lysates are assayed for protein concentration using the BioRad
10 protein assay system. Cell lysates are assayed for NADPH-dependent chemiluminescence by combining HBSS buffer, arachidonic acid, and 0.01 – 1 μ g protein in assay plates (96 well plastic plates). The reaction is initiated by adding 1.5 mM NADPH and 75 μ M lucigenin to the assay mix to give a final concentration of 200 μ M NADPH and 10 μ M lucigenin, and the
15 chemiluminescence is monitored immediately. The final assay volume as 150 μ l. The optimal arachidonic acid concentration is between 50-100 μ M. A Packard Lumicount luminometer is used to measure chemiluminescence of the reaction between lucigenin and superoxide at 37°C. The plate is monitored continuously for 60 minutes and the maximal relative luminescence unit
20 (RLU) value for each sample is used for the graph.

The presence of NaCl or KCl within a concentration range of 50-150 μ M is important for optimal activity. $MgCl_2$ (1-5 mM) further enhanced activity by about 2-fold. This cell-free assay for Nox 4 NADPH-oxidase activity and the cell-free assay for Nox 5 NADPH-oxidase are useful for
25 screening modulators (inhibitors or stimulators) of the Nox 4 enzyme and Nox 5 enzyme. The assay may also be used to detect Nox NADPH-oxidase activity in general and to screen for modulators (inhibitors or stimulators) of the Nox family of enzymes.

EXAMPLE 10

Nitro Blue Tetrazolium Reduction by Superoxide Generated by NIH 3T3 cells Transfected with the Nox 4 cDNA (SEQ ID NO:1) or the Nox 5 cDNA (SEQ ID NO:3)

- 5 Superoxide generation by intact cells is monitored by using superoxide dismutase-sensitive reduction of nitroblue tetrazolium. NEF2 (vector alone control), YA26 (Nox 4 (SEQ ID NO:1)-transfected), YA26 (Nox 5 (SEQ ID NO:3)-transfected), YA28 (Nox 4 (SEQ ID NO:1)-transfected) and YA28 (Nox 5 (SEQ ID NO:3)-transfected) cells are plated in six well plates at
10 500,000 cells per well. About 24 hours later, medium is removed from cells and the cells are washed once with 1 mL Hanks solution (Sigma, St. Louis, MO). About 1 mL of filtered 0.25% Nitro blue tetrazolium (NBT, Sigma) is added in Hanks without or with 600 units of superoxide dismutase (Sigma) and cells are incubated at 37°C in the presence of 5% CO₂. After 8 minutes the
15 cells are scraped and pelleted at more than 10,000g. The pellet is re-suspended in 1 mL of pyridine (Sigma) and heated for 10 minutes at 100°C to solubilize the reduced NBT. The concentration of reduced NBT is determined by measuring the absorbance at 510 nm, using an extinction coefficient of 11,000 M⁻¹cm⁻¹. Some wells are untreated and used to determine cell number.
20 Because superoxide dismutase is not likely to penetrate cells, superoxide must be generated extracellularly. The amount of superoxide generated by these cells is about 5-10% of that generated by activated human neutrophils.

EXAMPLE 11

- 25 *Modification of Intracellular Components in Nox 4 and Nox 5 Transfected Cells*

- To test whether superoxide generated by Nox 4 or Nox 5 can affect intracellular targets, aconitase activity in control and Nox-transfected cell lines is monitored using a method as described in Suh et al. (1999) *Nature* 401, 79-
30 82. Aconitase contains a four-iron-sulphur cluster that is highly susceptible to modification by superoxide, resulting in a loss of activity, and has been used as

a reporter of intra-cellular superoxide generation. Acotinase activity is determined as described in Gardner et al. (1995) *J. Biol. Chem.* 270, 13399-13405. Acotinase activity is significantly diminished in the Nox-transfected cell lines designated YA26, and YA28 as compared to the transfected control.

5 Approximately 50% of the aconitase in these cells is mitochondrial, based on differential centrifugation, and the cytosolic and mitochondrial forms were both affected. Control cytosolic and mitochondrial enzymes that do not contain iron-sulfur centers are not affected. Superoxide generated in Nox 4-transfected cells and Nox 5-transfected cells is therefore capable of reacting
10 with and modifying intracellular components.

EXAMPLE 12

Tumor Generation in Nude Mice Receiving Cells Transfected with the Human Nox 4 cDNA (SEQ ID NO:1) or the Human Nox 5 cDNA (SEQ ID NO:3)

15 About 2×10^6 NIH 3T3 cells (either Nox 4-transfected with SEQ ID NO:1, Nox 5-transfected with SEQ ID NO:3, or cells transfected using empty vector) are injected subdermally into the lateral aspect of the neck of 4-5 week old nude mice. Three to six mice are injected for each of three Nox 4-transfected cell lines, each of the Nox 5-transfected cell lines, and 3 mice are
20 injected with the cells transfected with empty vector (control). After 2 to 3 weeks, mice are sacrificed. The tumors are fixed in 10% formalin and characterized by histological analysis.

 In another study, 15 mice are injected with Nox 4-transfected NIH 3T3 cells. Of the 15 mice injected, 14 show large tumors within 17 days of
25 injection, and tumors show expression of Nox 4 mRNA.

 In another study, 15 mice are injected with Nox 5-transfected NIH 3T3 cells. Of the 15 mice injected, 14 show large tumors within 17 days of injection, and tumors show expression of Nox 5 mRNA.

30 EXAMPLE 13

Demonstration of the Role of Nox 4 and Nox 5 in Non-Cancerous Growth

A role for Nox 4 and Nox 5 in normal growth is demonstrated in rat aortic vascular smooth-muscle cells by using antisense to Nox 4 or Nox 5. Transfection with the antisense DNA results in a decrease in both superoxide generation and serum-dependent growth. Nox 4 and Nox 5 are therefore
5 implicated in normal growth in this cell type.

EXAMPLE 14

Expression of Human Nox 4 Protein (SEQ ID NO:2) and Human Nox 5 Protein (SEQ ID NO:4) in a Baculovirus Expression System

10 SEQ ID NO:2 and SEQ ID NO:4 are also expressed in insect cells using recombinant baculovirus. To establish the Nox 4 and Nox 5 expressing virus systems, the Nox 4 gene (SEQ ID NO:1) or the Nox 5 gene (SEQ ID NO:5) is initially cloned separately into the pBacPAK8 vector (Clontech, Palo Alto, CA) and recombinant baculovirus is constructed using standard methods
15 according to manufacturer's protocols. Briefly, PCR amplified Nox 4 DNA or Nox 5 DNA is cloned into the KpnI and EcoRI site of the vector. Primers used for PCR amplification are SEQ ID NOs:21, 22, 23 and 24. Sf9 insect cells (2×10^6 cells) are infected with 0.5 mg of linearized baculovirus DNA sold under the trademark BACULOGOLD® (PharMingen, San Diego, CA) and 5 mg
20 pBacPAC8 Nox 4 using Transfection Buffers A and B (PharMingen, San Diego, CA). After 5 days, the supernatants containing recombinant viruses are harvested and amplified by infecting fresh sf9 cells for 7 days. Amplification is carried out three times and the presence of the recombinant viruses containing Nox 4 DNA or Nox 5 DNA is confirmed by PCR using the same
25 primers. After three times amplification of viruses, plaque purification are carried out to obtain the high titer viruses. Approximately 2×10^8 sf9 cells in agar plates are infected for 5 days with serial dilutions of virus and are dyed with neutral red for easy detection of virus plaques. Selected virus plaques are extracted and the presence of the human Nox 4 DNA or human Nox 5 DNA is
30 confirmed again by PCR.

EXAMPLE 15

Antibodies to Human Nox 4 (SEQ ID NO:2) and Human Nox 5 (SEQ ID NO:4)

Polyclonal antibodies are raised separately in rabbits against human Nox 4 (SEQ ID NO:2) or human Nox 5 (SEQ ID NO: 4). Proteins are
5 separately conjugated to keyhole limpet hemocyanin (KLH) using glutaraldehyde.

Antigens are injected into different rabbits initially in complete Freund's adjuvant, and are boosted 4 times with antigen in incomplete Freund's adjuvant at intervals of every three weeks. Approximately 0.5 mg to 1 mg of
10 peptide is administered at each injection. Blood is drawn 1 week after each boost and a terminal bleed is carried out 2 weeks after the final boost. Anti Nox 4 and anti Nox 5 antibodies are purified on affinity columns to which are bound Nox 4 or Nox 5 using techniques known to one of ordinary skill in the art. Unbound protein is washed away with 20 ml of buffer. Elution of the
15 antibodies from the gel was performed with 6 ml of elution buffer (100 mM glycine/HCl, pH 2.5, 200 mM NaCl, and 0.5% Triton X-100). The eluate is then neutralized by adding 0.9 ml of 1 M Tris/HCl, pH 8.0.

The detection of antigens is performed using an enhanced chemiluminescence kit (Amersham, Buckinghamshire, UK). The affinity
20 purified antibodies to Nox 4 or to Nox 5 are used at a dilution of 1:1000 in a Western blot in which a total of 10 µg of protein is added to each lane.

EXAMPLE 16

Construction of a Reporter Construct for Nox-1

25 pGL3-basic (Promega, Madison, WI) was used as the parent vector. The pGL3-basic vector lacks eukaryotic promoter and enhancer sequences, allowing for maximum flexibility in cloning putative regulatory sequences. Expression of luciferase activity in cells transfected with this plasmid depends on insertion and proper orientation of a functional promoter upstream from
30 luc+. Potential enhancer elements can also be inserted upstream of the promoter or in the BamH I or Sal I sites downstream of the luc+ gene. Primers

SEQ ID NO: 25, 5'-GCTACTCGAGTGTGCCAATTTTCACCTGGCAT-3' and
SEQ ID NO:26, 5'-AACTCTCGAGTGTCAAGAGGTGGTTTGGAGC-3'
were used along with genomic DNA to obtain the promoter region of Nox 1
(SEQ ID NO:5) flanked by Xho restriction sites. The restriction sites were
5 then used to insert the Nox 1 promoter region into the pGL3 plasmid. (See Fig.
7). Successful transfection was determined by the activity of luciferase which
was measured using a luminometer.

EXAMPLE 17

10 *Use of the Reporter Construct as an Assay*

The construct from Example 16 is stably transfected into human
Caco-2 or HT-29 cells. Transfection is carried out as described in Sambrook et
al., Molecular Cloning, A Laboratory Manual, Volumes 1-3, 2nd edition, Cold
Spring Harbor Laboratory Press, N.Y., 1989. The SEQ ID NO:5 in pEF-PAC
15 and the empty vector are separately transfected into Caco-2 cells using Fugene
6 (Boeringer Mannheim). 10^5 to 10^3 cells stably transfected with human Nox
1 promoter gene SEQ ID NO:5 and with empty vector are prepared in 0.3%
warm (40°C) agar solution containing DMEM and 10% calf serum. Cells are
distributed onto a hardened 0.6% agar plate prepared with DMEM and 10%
20 calf serum. After three weeks in culture (37°C, 5% CO₂) colony formation is
observed by microscopy. About 2×10^6 cells maintained in DMEM
containing 10% calf serum are transfected with 10 µg of DNA. After 2 days,
cells are split and selected in the same medium containing 1mg/ml puromycin.
Colonies that survive in selection media for 10 to 14 days are subcultured
25 continuously in the presence of puromycin.

The colonies are used as a screening assay by adding compounds to
the media suspected of effecting the expression of ROI. Measurement of the
luciferase output indicates whether a compound enhanced or inhibited the
induction of the Nox 1 gene and facilitates the development of drugs based on
30 a compound's cellular effects.

EXAMPLE 18

Expression of Nox 3, Nox 4, and Nox 5 mRNA in Cancer Cells

Many cancer cells overproduce reactive oxygen species (Szatrowski and Nathan, 1991), and this may be causative in the transformed phenotype (Suh et al., 1999). The expression of Nox 1-5 was investigated in a variety of human tumor and other cell lines, to determine if these enzymes might account for reactive oxygen generation seen in some tumors. Expression of Nox family members in human cancers. RT-PCR was carried out as in Fig. 5. Fig. 6A shows Nox expression in the following cell lines: ES-2 (ovarian clear cell carcinoma), PA-1 (ovarian teratocarcinoma), Ovar-3 (ovarian adenocarcinoma), MDA-MB-231 (mammary adenocarcinoma), SKO-007 (plasmacytoma), Caco-2 (colon carcinoma), T84 (colon carcinoma), HEK293 (embryonic kidney transformed with adenovirus), and Hela (cervical adenocarcinoma). Fig. 6B show Nox expression in five cell lines derived from human glioblastomas, as well as from human astrocyte primary cultures. Fig. 6C shows the ratio of expression of gp91*phox*, Nox 4 and Nox 5 compared with G3PDH, obtained from real time PCR results.

As shown in Fig. 6A and 6B, Nox isoforms were expressed in 12 out of the 14 tumor or transformed cell lines examined. Nox 1 is expressed in two colon cancer lines, Caco-2 and T-84, as well as in the transformed cell line HEK293, and to a lesser extent in Hela cells. Nox 4 was seen in 11 of these cell lines, while Nox 5 was seen in 7. gp91*phox* was also expressed in more than half of the cell lines. The identity of the mRNAs was confirmed by sequencing as indicated in Figs. 5, 6A and B.

In live brain tumor cell lines derived from human glioblastomas, Nox 4 was always expressed, along with variable expression of Nox 5 and gp91*phox* (Fig. 6B). Real time PCR revealed that the ratio of expression of Nox to G3PDH varied significantly in the various tumor cell lines compared with primary human astrocytes (Fig. 6C). Although the cellular origin of glioblastomas has not been definitively established, this cancer type is thought by many workers to have arisen from the astrocytic lineage.

The expression of Nox forms in cancer and transformed cell lines did not correlate strictly with the expression in normal tissue, indicating that expression of Nox isoforms is sometimes altered in cancer cells. Thus, aberrant expression or regulation of Nox isoforms could account for the increased reactive oxygen generation seen in some cancer cells.

All patents, publications and abstracts cited above are incorporated herein by reference in their entirety. U.S. provisional patent applications serial nos. 60/249,305, 60/251,364, 60/289,172, 60/289,537 are hereby incorporated
5 by reference in their entirety. It should be understood that the foregoing relates only to preferred embodiments of the present invention and that numerous modifications or alterations may be made therein without departing from the spirit and the scope of the present invention as defined in the following claims.

CLAIMS

We claim:

- 5 1. A protein capable of stimulating superoxide production, wherein
the protein comprises the amino acid sequence of SEQ ID NO:2 or SEQ
ID NO:4, a fragment thereof, or a conservative substitution thereof.
- 10 2. An protein capable of stimulating superoxide production,
wherein the protein comprises the amino acid sequence of SEQ ID
NO:2 or SEQ ID NO:4, a deletion thereof or an addition thereto of no
more than about 20% of the amino acid sequence, or a conservative
substitution thereof, wherein the conservative substitution comprises
substitution of:
- 15 a) alanine, serine, or threonine for each other;
b) aspartic acid or glutamic acid for each other;
c) asparagine or glutamine for each other;
d) arginine or lysine for each other;
e) isoleucine, leucine, methionine, or valine for each other; or
20 f) phenylalanine, tyrosine, or tryptophan for each other.
3. The nucleotide sequence encoding for the protein, the fragment
thereof or the conservative substitution thereof as recited in Claim 1.
- 25 4. The nucleotide sequence of Claim 4, wherein the nucleotide
sequence comprises SEQ ID NO:1, a fragment thereof, or a
conservative substitution thereof, or SEQ ID NO:3, a fragment thereof,
or a conservative substitution thereof.

5. A vector, wherein the vector comprises a nucleotide sequence encoding for the protein, the fragment thereof or the conservative substitution thereof, as recited in Claim 1.
- 5 6. The vector of Claim 5, wherein the nucleotide sequence comprises SEQ ID NO:1 or SEQ ID NO:3, a fragment thereof, or a conservative substitution thereof.
7. A cell containing the vector of Claim 5 or Claim 6.
- 10 8. An antibody, wherein the antibody is capable of binding to the protein, the fragment thereof, or the conservative substitution thereof, as recited in Claim 1.
- 15 9. A method of stimulating superoxide formation comprising administration, in vitro or in vivo, of a composition comprising the protein, the fragment thereof, or the conservative substitution thereof of Claim 1 in a pharmaceutically acceptable carrier.
- 20 10. A method of stimulating superoxide formation comprising administration, in vitro or in vivo, of a composition comprising the vector of Claim 5 in a pharmaceutically acceptable carrier.
- 25 11. A method for determining the activity of a drug or a chemical comprising measuring the activity of the protein, the fragment thereof or the conservative substitution thereof, as recited in Claim 1, to stimulate superoxide production following administration of the drug or the chemical.
- 30 12. An isolated nucleotide sequence comprising the sequence of SEQ ID NO:5, a conservative substitution thereof or a fragment thereof.

13. A recombinant host cell comprising the sequence of Claim 12 in a reporter construct.
- 5 14. A method for determining the activity of a drug or a chemical comprising measuring the activity of the reporter construct of Claim 13 to generate a protein capable of stimulating superoxide production following administration of the drug or the chemical.
- 10 15. Use of the isolated protein of Claim 1 for preparation of a medicament useful for stimulating superoxide formation in an animal or a human following administration of the medicament to the animal or the human.
- 15 16. Use of the nucleotide sequence of Claim 3 for preparation of a medicament useful for stimulating superoxide formation in an animal or a human following administration of the medicament to the animal or the human.
- 20 17. Use of the isolated protein of Claim 1 for determining the activity of a drug or a chemical comprising measuring the activity of the protein, the fragment thereof or the conservative substitution thereof, as recited in Claim 1, to stimulate superoxide production following administration of the drug or the chemical.
