(57) **ABSTRACT**
A wearable display system includes a light projection system having one or more emissive microdisplays, e.g., micro-LED displays. The light projection system projects time-multiplexed left-eye and right-eye images, which pass through an optical router having a polarizer and a switchable polarization rotator. The optical router is synchronized with
(Continued)

the generation of images by the light projection system to impart a first polarization to left-eye images and a second different polarization to right-eye images. Light of the first polarization is incoupled into an eyepiece having one or more waveguides for outputting light to one of the left and right eyes, while light of the second polarization may be incoupled into another eyepiece having one or more waveguides for outputting light to the other of the left and right eyes. Each eyepiece may output incoupled light with variable amounts of wavefront divergence, to elicit different accommodation responses from the user's eyes.

**AUGMENTED AND VIRTUAL REALITY
DISPLAY SYSTEMS WITH SHARED
DISPLAY FOR LEFT AND RIGHT EYES**

PRIORITY CLAIM

This application claims priority from: U.S. Provisional Application No. 62/858,927 filed on Jun. 7, 2019 and titled “AUGMENTED AND VIRTUAL REALITY DISPLAY SYSTEMS WITH SHARED DISPLAY FOR LEFT AND RIGHT EYES”; U.S. Provisional Application No. 62/800,363 filed on Feb. 1, 2019 and titled “VIRTUAL AND AUGMENTED REALITY DISPLAY SYSTEMS WITH EMISSIVE MICRO-DISPLAYS”; U.S. Provisional Application No. 62/911,018 filed on Oct. 4, 2019 and titled “AUGMENTED AND VIRTUAL REALITY DISPLAY SYSTEMS WITH SHARED DISPLAY FOR LEFT AND RIGHT EYES”; and U.S. Provisional Application No. 62/786,199 filed on Dec. 28, 2018 and titled “LOW MOTION-TO-PHOTON LATENCY ARCHITECTURE FOR AUGMENTED AND VIRTUAL REALITY DISPLAY SYSTEMS”. The above-noted applications are hereby incorporated by reference herein in their entireties.

INCORPORATION BY REFERENCE

This application incorporates by reference the entireties of each of the following: U.S. application Ser. No. 14/555,585 filed on Nov. 27, 2014, published on Jul. 23, 2015 as U.S. Publication No. 2015/0205126; U.S. application Ser. No. 14/690,401 filed on Apr. 18, 2015, published on Oct. 22, 2015 as U.S. Publication No. 2015/0302652; U.S. application Ser. No. 14/212,961 filed on Mar. 14, 2014, now U.S. Pat. No. 9,417,452 issued on Aug. 16, 2016; U.S. application Ser. No. 14/331,218 filed on Jul. 14, 2014, published on Oct. 29, 2015 as U.S. Publication No. 2015/0309263; U.S. Patent App. Pub. No. 2018/0061121, published Mar. 1, 2018; U.S. patent application Ser. No. 16/221,065, filed Dec. 14, 2018; U.S. Patent App. Pub. No. 2018/0275410, published Sep. 27, 2018; U.S. Provisional Application No. 62/786,199, filed Dec. 28, 2018; and U.S. application Ser. No. 16/221,359, filed on Dec. 14, 2018; U.S. Provisional Application No. 62/702,707, filed on Jul. 24, 2018; and U.S. application Ser. No. 15/481,255, filed Apr. 6, 2017.

BACKGROUND

Field

The present disclosure relates to display systems and, more particularly, to augmented and virtual reality display systems.

Description of the Related Art

Modern computing and display technologies have facilitated the development of systems for so called “virtual reality” or “augmented reality” experiences, in which digitally reproduced images or portions thereof are presented to a user in a manner wherein they seem to be, or may be perceived as, real. A virtual reality, or “VR”, scenario typically involves the presentation of digital or virtual image information without transparency to other actual real-world visual input; an augmented reality, or “AR”, scenario typically involves presentation of digital or virtual image information as an augmentation to visualization of the actual world around the user. A mixed reality, or “MR”, scenario is

a type of AR scenario and typically involves virtual objects that are integrated into, and responsive to, the natural world. For example, an MR scenario may include AR image content that appears to be blocked by or is otherwise perceived to interact with objects in the real world.

Referring to FIG. 1, an augmented reality scene 10 is depicted. The user of an AR technology sees a real-world park-like setting 20 featuring people, trees, buildings in the background, and a concrete platform 30. The user also perceives that he/she “sees” “virtual content” such as a robot statue 40 standing upon the real-world platform 30, and a flying cartoon-like avatar character 50 which seems to be a personification of a bumble bee. These elements 50, 40 are “virtual” in that they do not exist in the real world. Because the human visual perception system is complex, it is challenging to produce AR technology that facilitates a comfortable, natural-feeling, rich presentation of virtual image elements amongst other virtual or real-world imagery elements.

SUMMARY

In some embodiments, a head-mounted display system comprises a head-mountable frame, a light projection system, a left eyepiece supported by the frame, a right eyepiece supported by the frame, and an optical router. The light projection system comprises an emissive micro-display and is configured to output image light comprising left-eye image light for forming left-eye images time-multiplexed with right-eye image light for forming right-eye images. The optical router is configured to receive the image light from the light projection system, and provide, at different times, the left-eye image light to the left eyepiece and the right-eye image light to the right eyepiece.

Some additional examples of embodiments are provided below.

Example 1. A head-mounted display system comprising: a head-mountable frame; a light projection system comprising an emissive micro-display, wherein the light projection system is configured to output image light comprising left-eye image light for forming left-eye images time-multiplexed with right-eye image light for forming right-eye images; a left eyepiece supported by the frame; a right eyepiece supported by the frame; and an optical router configured to: receive the image light from the light projection system, and provide, at different times, the left-eye image light to the left eyepiece and the right-eye image light to the right eyepiece.

Example 2. The head-mounted display system of Example 1, wherein the optical router comprises: a polarizer configured to receive the image light and to output the image light with a first polarization state; and a switchable polarization rotator configured to receive the image light with the first polarization state and to selectively change a polarization state of the received image light to a second polarization state.

Example 3. The head-mounted display system of Example 2, wherein the electrically-switchable polarization rotator comprises a switchable half-wave plate (HWP).

Example 4. The head-mounted display system of Example 2, further comprising control electronics configured to synchronize:

generation of left-eye image images by the light projection system and routing of the left-eye image light to the left eyepiece by the optical router; and

generation of the right-eye images by the light projection system and routing of the right-eye image light to the right eyepiece by the optical router;

wherein the electrically-switchable polarization rotator is synchronized, by the control electronics, with the light projection system to output left-eye image light with a first polarization state and to output right-eye image light with a second polarization different from the first polarization state.

Example 5. The head-mounted display system of Example 2, wherein the optical router further comprises a polarization-sensitive reflector configured to receive the image light from the switchable polarization rotator,

wherein the polarization-sensitive reflector is configured to reflect image light having the first polarization state and transmit image light having the second polarization state.

Example 6. The head-mounted display system of Example 5, wherein the polarization-sensitive reflector is configured to:

direct left-eye image light having one of the first and second polarization states towards the left eyepiece; and

direct right-eye image light having the other of the first and second polarization states towards the right eyepiece.

Example 7. The head-mounted display system of Example 5, wherein the polarization-sensitive reflector comprises a polarization beam splitter.

Example 8. The head-mounted display system of Example 1, wherein the left eyepiece comprises one or more left-eye waveguides forming a left-eye waveguide assembly, each left-eye waveguide comprising:

a left-eye in-coupling optical element configured to in-couple image light into the left-eye waveguide; and
a left-eye out-coupling optical element configured to out-couple in-coupled image light out of the left-eye waveguide, and

the right eyepiece comprises one or more right-eye waveguides forming a right-eye waveguide assembly, each right-eye waveguide comprising:

a right-eye in-coupling optical element configured to in-couple image light into the right-eye waveguide; and
a right-eye out-coupling optical element configured to out-couple in-coupled image light out of the right-eye waveguide.

Example 9. The head-mounted display system of Example 8, wherein the left-eye waveguide assembly is configured to output the in-coupled light with variable amounts of wavefront divergence corresponding to a plurality of depth planes and wherein the right-eye waveguide assembly is configured to output the out-coupled light with variable amounts of wavefront divergence corresponding to the plurality of depth planes.

Example 10. The head-mounted display system of Example 8, wherein the left-eye waveguide assembly comprises a first stack of waveguides, wherein the right-eye waveguide assembly comprises a second stack of waveguides, wherein the light projection system is configured to output light of a plurality of component colors, wherein each of the left-eye and right-eye waveguide assemblies comprises at least one dedicated waveguide for light of each component color.

Example 11. The head-mounted display system of Example 1, wherein the left eyepiece comprises one or more left-eye waveguides, each left-eye waveguide comprising:

a left-eye polarization-sensitive in-coupling optical element configured to in-couple light having the first polarization state into the left-eye waveguide; and
a left-eye out-coupling optical element configured to out-couple in-coupled light out of the left-eye waveguide.

Example 12. The head-mounted display system of Example 11, wherein the right eyepiece comprises:

one or more right-eye waveguides, each right-eye waveguide comprising:

a right-eye polarization-sensitive in-coupling optical element configured to in-couple light having the second polarization state into the right-eye waveguide; and
a right-eye out-coupling optical element configured to out-couple in-coupled light out of the right-eye waveguide.

Example 13. The head-mounted display of Example 12, wherein the left-eye polarization-sensitive in-coupling optical element and the right-eye polarization-sensitive in-coupling optical element are disposed in a same image light path.

Example 14. The head-mounted display of Example 13, further comprising a cleanup polarizer disposed between the left-eye polarization-sensitive in-coupling optical element and the right-eye polarization-sensitive in-coupling optical element, wherein the cleanup polarizer is configured to:

block light not having a polarization for which the downstream polarization-sensitive in-coupling optical element is configured sensitive.

Example 15. The head-mounted display system of Example 1, wherein the emissive micro-display comprises a micro-LED display.

Example 16. The head-mounted display system of Example 1, further comprising a plurality of emissive micro-displays, wherein each micro-LED display is a monochromatic and configured to emit light of a component color.

Example 17. The head-mounted display system of Example 16, further comprising an X-cube prism, wherein each of the emissive micro-LED displays face a different side of the X-cube prism.

Example 18. The head-mounted display system of Example 17, wherein each micro-LED display comprises an array of light emitters, further comprising a plurality of arrays of light collimators, wherein each micro-display has an associated array of light collimators, and wherein each array of light collimators is configured to capture and reduce an angular emission profile of light from the micro-display.

Example 19. The head-mounted display system of Example 18, wherein the light collimators comprise micro-lenses.

Example 20. The head-mounted display system of Example 18, wherein the light collimators comprise nano-lenses.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates a user's view of augmented reality (AR) through an AR device.

FIG. 2 illustrates a conventional display system for simulating three-dimensional imagery for a user.

FIGS. 3A-3C illustrate relationships between radius of curvature and focal radius.

FIG. 4A illustrates a representation of the accommodation-vergence response of the human visual system.

5

FIG. 4B illustrates examples of different accommodative states and vergence states of a pair of eyes of the user.

FIG. 4C illustrates an example of a representation of a top-down view of a user viewing content via a display system.

FIG. 4D illustrates another example of a representation of a top-down view of a user viewing content via a display system.

FIG. 5 illustrates aspects of an approach for simulating three-dimensional imagery by modifying wavefront divergence.

FIG. 6 illustrates an example of a waveguide stack for outputting image information to a user.

FIG. 7 illustrates an example of exit beams outputted by a waveguide.

FIG. 8 illustrates an example of a stacked eyepiece in which each depth plane includes images formed using multiple different component colors.

FIG. 9A illustrates a cross-sectional side view of an example of a set of stacked waveguides that each includes an in-coupling optical element.

FIG. 9B illustrates a perspective view of an example of the plurality of stacked waveguides of FIG. 9A.

FIG. 9C illustrates a top-down plan view of an example of the plurality of stacked waveguides of FIGS. 9A and 9B.

FIG. 9D illustrates a top-down plan view of another example of a plurality of stacked waveguides.

FIG. 9E illustrates an example of wearable display system.

FIG. 10 illustrates an example of a wearable display system with a light projection system having a spatial light modulator and a separate light source.

FIG. 11A illustrates an example of a wearable display system with a light projection system having multiple emissive micro-displays.

FIG. 11B illustrates an example of an emissive micro-display with an array of light emitters.

FIG. 12 illustrates another example of a wearable display system with a light projection system having multiple emissive micro-displays and associated light redirecting structures.

FIG. 13A illustrates an example of a side-view of a wearable display system with a light projection system having multiple emissive micro-displays and an eyepiece having waveguides with overlapping and laterally-shifted light in-coupling optical elements.

FIG. 13B illustrates another example of a wearable display system with a light projection system having multiple emissive micro-displays configured to direct light to a single light in-coupling area of an eyepiece.

FIG. 14 illustrates an example of a wearable display system with a single emissive micro-display.

FIG. 15 illustrates a side view of an example of an eyepiece having a stack of waveguides with overlapping in-coupling optical elements.

FIG. 16 illustrates a side view of an example of a stack of waveguides with color filters for mitigating ghosting or crosstalk between waveguides.

FIG. 17 illustrates an example of a top-down view of the eyepieces of FIGS. 15 and 16.

FIG. 18 illustrates another example of a top-down view of the eyepieces of FIGS. 15 and 16.

FIG. 19A illustrates a side view of an example of an eyepiece having a stack of waveguides with overlapping and laterally-shifted in-coupling optical elements.

6

FIG. 19B illustrates a side view of an example of the eyepiece of FIG. 19A with color filters for mitigating ghosting or crosstalk between waveguides.

FIG. 20A illustrates an example of a top-down view of the eyepieces of FIGS. 19A and 19B.

FIG. 20B illustrates another example of a top-down view of the eyepieces of FIGS. 19A and 19B.

FIG. 21 illustrates a side view of an example of re-bounce in a waveguide.

FIGS. 22A-22C illustrate examples of top-down views of an eyepiece having in-coupling optical elements configured to reduce re-bounce.

FIGS. 23A-23C illustrate additional examples of top-down views of an eyepiece having in-coupling optical elements configured to reduce re-bounce.

FIG. 24A illustrates an example of angular emission profiles of light emitted by individual light emitters of an emissive micro-display, and light captured by projection optics.

FIG. 24B illustrates an example of the narrowing of angular emission profiles using an array of light collimators.

FIG. 25A illustrates an example of a side view of an array of tapered reflective wells for directing light to projection optics.

FIG. 25B illustrates an example of a side view of an asymmetric tapered reflective well.

FIGS. 26A-26C illustrate examples of differences in light paths for light emitters at different positions relative to center lines of overlying lens.

FIG. 27 illustrates an example of a side view of individual light emitters of an emissive micro-display with an overlying nano-lens array.

FIG. 28 is a perspective view of an example of the emissive micro-display of FIG. 27.

FIG. 29 illustrates an example of a wearable display system with the full-color emissive micro-display of FIG. 28.

FIG. 30A illustrates an example of a wearable display system with an emissive micro-display and an associated array of light collimators.

FIG. 30B illustrates an example of a light projection system with multiple emissive micro-displays, each with an associated array of light collimators.

FIG. 30C illustrates an example of a wearable display system with multiple emissive micro-displays, each with an associated array of light collimators.

FIGS. 31A and 31B illustrate examples of waveguide assemblies having variable focus elements for varying the wavefront divergence of light to a viewer.

FIG. 32 illustrates an example of a wearable display system with a light projection system having one or more emissive micro-displays, and an optical router for selectively directing light to left and right eyepieces.

FIG. 33 illustrates an example of a wearable display system having an optical router that includes a polarization-sensitive reflective structure for selectively directing images to left and right eyepieces.

FIG. 34 illustrates an example of a wearable display system with an optical router that switches polarization states of incident image light, and left and right eyepieces having in-coupling optical elements that selectively in-couple light of different polarization states.

DETAILED DESCRIPTION

As described herein, AR and/or VR systems may display virtual content to a user, or viewer. This content may be

displayed on a head-mounted display, e.g., as part of eye-wear, that projects image information to the user's eyes. In addition, where the system is an AR system, the display may also transmit light from a surrounding environment to the user's eyes, to allow a view of the surrounding environment. As used herein, it will be appreciated that a "head-mounted" or "head mountable" display is a display that may be mounted on the head of the user or viewer.

Many head-mounted display systems utilize transmissive or reflective spatial light modulators to form images that are presented to the user. A light source emits light, which is directed to the spatial light modulator, which then modulates the light, which is then directed to the user. Lens structures may be provided between the light source and the spatial light modulator to focus light from the light source onto the spatial light modulator. Undesirably, the light source and related optics may add bulkiness and weight to the display system. This bulkiness or weight may be compounded since different images may be presented to the left and right eyes of the user and, as such, each eye may have a dedicated associated light source and spatial light modulator. The bulk and weight of the associate light sources and associated spatial light modulators may adversely impact the comfort of the display system and the ability to wear the system for long durations.

In addition, it has been found that the frame rate limitations of some display systems may cause viewing discomfort. Some display systems use spatial light modulators to form images. Many spatial light modulators utilize movement of optical elements to modulate the intensity of light outputted by the spatial light modulator, to thereby form the images. For example, MEMS-based spatial light modulators may utilize moving mirrors to modulate incident light, while LCoS-based displays may utilize the movement of liquid crystal molecules to modulate light. Other AR or VR systems may utilize scanning-fiber displays, in which the end of an optical fiber physically moves across an area while outputting light. The light outputted by the optical fiber is timed with the position of the end of the fiber, thereby effectively mimicking pixels at different locations, and thereby forming images. The requirement that the optical fibers, mirrors, and liquid crystal molecules physically move limits the speed at which individual pixels may change states and also constrains the frame rate of displays using these optical elements.

Such limitations may cause viewing discomfort due to, e.g., motion blur and/or mismatches between the orientation of the user's head and the displayed image. For example, there may be latency in the detection of the orientation of the user's head and the presentation of images consistent with that orientation. In the timespan between detecting the orientation and presenting an image to the user, the user's head may have moved. The presented image, however, may correspond to a view of an object from a different orientation. Such a mismatch between the orientation of the user's head and the presented image may cause discomfort in the user (e.g., nausea).

In addition, scanning-fiber displays may present other undesirable optical artifacts due to, e.g., the small cross-section of the fibers, which requires the use of a high-intensity light source to form images of desirable apparent brightness. Suitable high-intensity light sources include lasers, which output coherent light. Undesirably, the use of coherent light may cause optical artifacts.

Advantageously, display systems utilizing emissive micro-displays as described herein may allow for a low-weight and compact form factor, and may also provide a

high frame rate and low motion blur. Preferably, the micro-displays are emissive micro-displays, which provide advantages for high brightness and high pixel density. In some embodiments, the emissive micro-displays are micro-LED displays. In some other embodiments, the emissive micro-displays are micro-OLED displays. In some embodiments, the emissive micro-displays comprise arrays of light emitters having a pitch of, e.g., less than 10 μm , less than 8 μm , less than 6 μm , less than 5 μm , or less than 2 μm , including 1-5 μm , and an emitter size of 2 μm or less, 1.7 μm or less, or 1.3 μm or less. In some embodiments, the emitter size is within a range having an upper limit of the above-noted sizes and a lower limit of 1 μm . In some embodiments, the ratio of emitter size to pitch is 1:1 to 1:5, 1:2 to 1:4, or 1:2 to 1:3, which may have advantages for individual control of emitters and efficient utilization of emitted light by eyepieces, as discussed further herein.

In some embodiments, a plurality of emissive micro-displays may be utilized to form images for a head-mounted display system. The light containing the image information for forming these images may be referred to as image light. It will be appreciated that image light may vary in, e.g., wavelength, intensity, polarization, etc. The emissive micro-displays output image light to an eyepiece, which then relays the light to an eye of the user.

In some embodiments, a head mounted display system may include left and right eyepieces for relaying image light to the user's left and right eyes, respectively. The head mounted display system may also include a light projection system and an optical router for routing image light to an appropriate one of the left and right eyepieces. The light projection system may be configured to generate distinct images (e.g., image frames) for both left and right eyepieces of the display system, and the optical router may be configured to direct the left-eye and right-eye image frames to the corresponding one of the left and right eyepieces. In some embodiments, the light projection system utilizes an emissive micro-display, which has advantages for high frame rates, which facilitate the use of a common light projection system for both the left and right eyepieces.

In some embodiments, the light projection system may be configured to time-multiplex left and right eyepiece image frames and the optical router may be configured to route the left image frames to the left eyepiece and the right image frames to the right eyepiece. In some embodiments, the light projection system may utilize one or more emissive micro-displays with a frame rate of 120 Hz or more, which advantageously may provide left-eye image frames at frame rates of 60 Hz or more to a left eyepiece, while also providing right-eye image frames at frame rates of 60 Hz or more to a right eyepiece. The micro-displays may interleave in time (e.g., time-multiplex) the left-eye and right-eye image frames, which may also be referred to as left-eye and right-eye images. For example, the micro-displays may alternate between generating a left-eye image frame (that is, an image frame of content intended for the left-eye) that is routed to a left eyepiece and a right-eye image frame (that is, an image frame of content intended for the right-eye) that is routed to a right eyepiece. The optical router may demultiplex the left-eye and right-eye image frames by routing left-eye image frames to the left eyepiece, and right-eye image frames to the right eyepiece.

In some embodiments, the optical router may be an electrically switchable device which provides selectable switching of the path of the light being outputted by the router and/or which provides selectable switching of a property of the light to change a way that the light interacts

with (e.g. propagates through) subsequent downstream structures. In some embodiments, routing light via the optical router to one of the left or right eyepieces may include changing a polarization state of the light.

In some embodiments, the optical router may be a mechanically switchable device, such as a moveable mirror that switches between: a first orientation that reflects light to one of the right or left eyepieces, and a second orientation that reflects light to the other of the right or left eyepieces. For example, the optical router may comprise a MEMS mirror or a scanning mirror.

For example, a first reflector that selectively reflects light of a particular polarization state may be utilized to reflect light of a first polarization state towards a corresponding eyepiece, while transmitting light of a second polarization state to a second reflector, which then reflects the remaining light to the other eyepiece. In some embodiments, the second reflector may selectively reflect light of the second polarization state to the other eyepiece.

In some embodiments, the left and right eyepieces may have in-coupling optical elements that overlap (e.g., are both in a common path of light from the light projection system). The optical router routes light to the appropriate eyepiece by changing a polarization state of the output image light so that, for example, left eyepiece image frames are formed by light with the appropriate polarization state to be in-coupled by the in-coupling optical elements of the left eyepiece, and right eyepiece image frames are formed by light with the appropriate polarization state to be in-coupled by the in-coupling optical elements of the right eyepiece.

Thus, in some embodiments, the left and right eyepieces share a common light projection system, which may reduce bulkiness and weight relative to using dedicated light projection systems for each of the left and right eyepieces. In addition, the light projection system preferably utilizes one or more emissive micro-displays, which further provides advantages (e.g., for reducing bulkiness and weight), as discussed herein.

In some embodiments, a plurality of emissive micro-displays may be utilized and positioned at different sides of an optical combiner, e.g., an X-cube prism or dichroic X-cube. The X-cube prism receives light rays from different micro-displays on different faces of the cube and outputs the light rays from the same face of the cube. The outputted light may be directed towards projection optics, which is configured to converge or focus the image light onto the eyepiece.

In some embodiments, the plurality of emissive micro-displays comprises monochrome micro-displays, which are configured to output light of a single component color. Combining various component colors forms a full color image. In some other embodiments, one or more of the emissive micro-displays may have sub-pixels configured to emit light of two or more, but not all, component colors utilized by the display system. For example, a single emissive micro-display may have sub-pixels which emit light of the colors blue and green, while a separate emissive micro-display on a different face of the X-cube may have pixels configured to emit red light. In some embodiments, the plurality of micro-displays are each full-color displays comprising, e.g., pixels formed of multiple sub-pixels configured to emit light of different component colors. Advantageously, combining the light of multiple full-color micro-displays may increase display brightness and dynamic range.

It will be appreciated that the emissive micro-displays may comprise arrays of light emitters. The light emitters may emit light with a Lambertian angular emission profile. Undesirably, such an angular remission profile may “waste”

light, since only a small portion of the emitted light may ultimately be incident on the eyepiece. In some embodiments, light collimators may be utilized to narrow the angular emission profile of light emitted by the light emitters. As used herein, a light collimator is an optical structure which narrows the angular emission profile of incident light; that is, the light collimator receives light from an associated light emitter with a relatively wide initial angular emission profile and outputs that light with a narrower angular emission profile than the wide initial angular emission profile. In some embodiments, the rays of light exiting the light collimator are more parallel than the rays of light received by the light collimator, before being transmitted through and exiting the collimator. Examples of light collimators include micro-lenses, nano-lenses, reflective wells, metasurfaces, and liquid crystal gratings. In some embodiments, the light collimators may be configured to steer light to ultimately converge on different laterally-shifted light-coupling optical elements. In some embodiments, each light emitter has a dedicated light collimator. The light collimators are preferably positioned directly adjacent or contacting the light emitters, to capture a large proportion of the light emitted by the associated light emitters.

In some embodiments, a single emissive micro-display may be utilized to direct light to the eyepiece. For example, the single emissive micro-display may be a full-color display comprising light emitters that emit light of different component colors. In some embodiments, the light emitters may form groups, which are localized in a common area, with each group comprising light emitters which emit light of each component color. In such embodiments, each group of light emitters may share a common micro-lens. Advantageously, light of different colors from different light emitters take a different path through the micro-lens, which may be manifested in light of different component colors being incident on different in-coupling optical elements of an eyepiece, as discussed herein.

In some embodiments, the full-color micro-display may comprise repeating groups of light emitters of the same component color. For instance, the micro-display may include rows of light emitters, with the light emitters of each individual row configured to emit light of the same color. Thus, different rows may emit light of different component colors. In addition, the micro-display may have an associated array of light collimators configured to direct light to a desired location on an eyepiece, e.g., to an associated in-coupling optical element. Advantageously, while the individual light emitters of such a full-color micro-display may not be positioned to form a high-quality full-color image, as viewed directly on the micro-display, the lens array appropriately steers the light from the light emitters to the eyepiece, which combines monochrome images formed by light emitters of different colors, thereby forming a high-quality full-color image.

In some embodiments, the eyepiece receiving image light from the micro-displays may comprise a waveguide assembly. The area of a waveguide of the waveguide assembly on which the image light is incident may include in-coupling optical elements which in-couple incident image light, such that the light propagates through the waveguide by total internal reflection (TIR). In some embodiments, the waveguide assembly may include a stack of waveguides, each of which has an associated in-coupling optical element. Different in-coupling optical elements may be configured to in-couple light of different colors, such that different waveguides may be configured to propagate light of different colors therein. The waveguides may include out-coupling

optical elements, which out-couple light propagating therein, such that the out-coupled light propagates towards the eye of the user. In some other embodiments, the waveguide assembly may include a single waveguide having an associated in-coupling optical element configured to in-couple light of different component colors.

In some embodiments, the in-coupling optical elements are laterally shifted, as seen from the projection optics. Different in-coupling optical elements may be configured to in-couple light of different colors. Preferably, image light of different colors take different paths to the eyepiece and, thus, impinge upon different corresponding in-coupling optical elements.

In some other embodiments, other types of eyepieces or optics for relaying image light to the eyes of the user may be utilized. For example, as discussed herein, the eyepiece may include one or more waveguides which propagates image light therein by TIR. As another example, the eyepiece may include a birdbath combiner comprising a semitransparent mirror that both directs image light to a viewer and allows a view of the ambient environment.

In some embodiments, the eyepiece may be configured to selectively output light with different amounts of wavefront divergence, to provide virtual content at a plurality of virtual depth planes (also referred to simply as “depth planes” herein) perceived to be at different distances away from the user. For example, the eyepiece may comprise a plurality of waveguides each having out-coupling optical elements with different optical power to output light with different amounts of wavefront divergence. In some other embodiments, a variable focus element may be provided between the eyepiece and the user’s eye. The variable focus element may be configured to dynamically change optical power to provide the desired wavefront divergence for particular virtual content. In some embodiments, as an alternative to, or in addition to waveguide optical structures for providing optical power, the display systems may also include a plurality of lenses that provide or additionally provide optical powers.

In addition to the compact form factor and high frame rates discussed above, emissive micro-displays according to some embodiments may provide one of more of the following advantages. For example, the micro-displays may provide exceptionally small pixel pitches and high pixel density. The micro-displays may also provide high luminance and efficiency. For example, the light emitters of the emissive micro-displays may only consume power to emit light when the light emitters are needed provide content with luminance. This is in contrast to other display technologies in which the light source may illuminate an entire panel of pixels, whether or not some of those pixels are dark. Further, it will be appreciated that the human visual system integrates received light over time and the light emitters of emissive micro-displays, such as micro-LEDs, have advantageously high duty cycles (e.g., including a short activation period for a light emitter in a micro-display to rise from an “off” to a full “on” state, and a correspondingly short time to fall from an “on” state to “off” state allow the light emitters to emit light at the on level for a large percentage of each cycle). As a result, the power used to generate an image with a given perceived brightness may be less as compared to conventional display technologies with lower duty cycles. In some embodiments, the duty cycle may be 70% or more, 80% or more, or 90% or more. In some embodiments, the duty cycle may be about 99%. In addition, as noted herein, micro-displays may facilitate exceptionally high frame rates, which

may provide advantages including reducing mismatches between the position of a user’s head and the displayed content.

Reference will now be made to the drawings, in which like reference numerals refer to like parts throughout. Unless indicated otherwise, the drawings are schematic and not necessarily drawn to scale.

FIG. 2 illustrates a conventional display system for simulating three-dimensional imagery for a user. It will be appreciated that a user’s eyes are spaced apart and that, when looking at a real object in space, each eye will have a slightly different view of the object and may form an image of the object at different locations on the retina of each eye. This may be referred to as binocular disparity and may be utilized by the human visual system to provide a perception of depth. Conventional display systems simulate binocular disparity by presenting two distinct images **190, 200** with slightly different views of the same virtual object—one for each eye **210, 220**—corresponding to the views of the virtual object that would be seen by each eye were the virtual object a real object at a desired depth. These images provide binocular cues that the user’s visual system may interpret to derive a perception of depth.

With continued reference to FIG. 2, the images **190, 200** are spaced from the eyes **210, 220** by a distance **230** on a z-axis. The z-axis is parallel to the optical axis of the viewer with their eyes fixated on an object at optical infinity directly ahead of the viewer. The images **190, 200** are flat and at a fixed distance from the eyes **210, 220**. Based on the slightly different views of a virtual object in the images presented to the eyes **210, 220**, respectively, the eyes may naturally rotate such that an image of the object falls on corresponding points on the retinas of each of the eyes, to maintain single binocular vision. This rotation may cause the lines of sight of each of the eyes **210, 220** to converge onto a point in space at which the virtual object is perceived to be present. As a result, providing three-dimensional imagery conventionally involves providing binocular cues that may manipulate the vergence of the user’s eyes **210, 220**, and that the human visual system interprets to provide a perception of depth.

Generating a realistic and comfortable perception of depth is challenging, however. It will be appreciated that light from objects at different distances from the eyes have wavefronts with different amounts of divergence. FIGS. 3A-3C illustrate relationships between distance and the divergence of light rays. The distance between the object and the eye **210** is represented by, in order of decreasing distance, **R1, R2, and R3**. As shown in FIGS. 3A-3C, the light rays become more divergent as distance to the object decreases. Conversely, as distance increases, the light rays become more collimated. Stated another way, it may be said that the light field produced by a point (the object or a part of the object) has a spherical wavefront curvature, which is a function of how far away the point is from the eye of the user. The curvature increases with decreasing distance between the object and the eye **210**. While only a single eye **210** is illustrated for clarity of illustration in FIGS. 3A-3C and other figures herein, the discussions regarding eye **210** may be applied to both eyes **210** and **220** of a viewer.

With continued reference to FIGS. 3A-3C, light from an object that the viewer’s eyes are fixated on may have different degrees of wavefront divergence. Due to the different amounts of wavefront divergence, the light may be focused differently by the lens of the eye, which in turn may require the lens to assume different shapes to form a focused image on the retina of the eye. Where a focused image is not

formed on the retina, the resulting retinal blur acts as a cue to accommodation that causes a change in the shape of the lens of the eye until a focused image is formed on the retina. For example, the cue to accommodation may trigger the ciliary muscles surrounding the lens of the eye to relax or contract, thereby modulating the force applied to the suspensory ligaments holding the lens, thus causing the shape of the lens of the eye to change until retinal blur of an object of fixation is eliminated or minimized, thereby forming a focused image of the object of fixation on the retina (e.g., fovea) of the eye. The process by which the lens of the eye changes shape may be referred to as accommodation, and the shape of the lens of the eye required to form a focused image of the object of fixation on the retina (e.g., fovea) of the eye may be referred to as an accommodative state.

With reference now to FIG. 4A, a representation of the accommodation-vergence response of the human visual system is illustrated. The movement of the eyes to fixate on an object causes the eyes to receive light from the object, with the light forming an image on each of the retinas of the eyes. The presence of retinal blur in the image formed on the retina may provide a cue to accommodation, and the relative locations of the image on the retinas may provide a cue to vergence. The cue to accommodation causes accommodation to occur, resulting in the lenses of the eyes each assuming a particular accommodative state that forms a focused image of the object on the retina (e.g., fovea) of the eye. On the other hand, the cue to vergence causes vergence movements (rotation of the eyes) to occur such that the images formed on each retina of each eye are at corresponding retinal points that maintain single binocular vision. In these positions, the eyes may be said to have assumed a particular vergence state. With continued reference to FIG. 4A, accommodation may be understood to be the process by which the eye achieves a particular accommodative state, and vergence may be understood to be the process by which the eye achieves a particular vergence state. As indicated in FIG. 4A, the accommodative and vergence states of the eyes may change if the user fixates on another object. For example, the accommodated state may change if the user fixates on a new object at a different depth on the z-axis.

Without being limited by theory, it is believed that viewers of an object may perceive the object as being “three-dimensional” due to a combination of vergence and accommodation. As noted above, vergence movements (e.g., rotation of the eyes so that the pupils move toward or away from each other to converge the lines of sight of the eyes to fixate upon an object) of the two eyes relative to each other are closely associated with accommodation of the lenses of the eyes. Under normal conditions, changing the shapes of the lenses of the eyes to change focus from one object to another object at a different distance will automatically cause a matching change in vergence to the same distance, under a relationship known as the “accommodation-vergence reflex.” Likewise, a change in vergence will trigger a matching change in lens shape under normal conditions.

With reference now to FIG. 4B, examples of different accommodative and vergence states of the eyes are illustrated. The pair of eyes 222a is fixated on an object at optical infinity, while the pair eyes 222b are fixated on an object 221 at less than optical infinity. Notably, the vergence states of each pair of eyes is different, with the pair of eyes 222a directed straight ahead, while the pair of eyes 222 converge on the object 221. The accommodative states of the eyes forming each pair of eyes 222a and 222b are also different, as represented by the different shapes of the lenses 210a, 220a.

Undesirably, many users of conventional “3-D” display systems find such conventional systems to be uncomfortable or may not perceive a sense of depth at all due to a mismatch between accommodative and vergence states in these displays. As noted above, many stereoscopic or “3-D” display systems display a scene by providing slightly different images to each eye. Such systems are uncomfortable for many viewers, since they, among other things, simply provide different presentations of a scene and cause changes in the vergence states of the eyes, but without a corresponding change in the accommodative states of those eyes. Rather, the images are shown by a display at a fixed distance from the eyes, such that the eyes view all the image information at a single accommodative state. Such an arrangement works against the “accommodation-vergence reflex” by causing changes in the vergence state without a matching change in the accommodative state. This mismatch is believed to cause viewer discomfort. Display systems that provide a better match between accommodation and vergence may form more realistic and comfortable simulations of three-dimensional imagery.

Without being limited by theory, it is believed that the human eye typically may interpret a finite number of depth planes to provide depth perception. Consequently, a highly believable simulation of perceived depth may be achieved by providing, to the eye, different presentations of an image corresponding to each of these limited numbers of depth planes. In some embodiments, the different presentations may provide both cues to vergence and matching cues to accommodation, thereby providing physiologically correct accommodation-vergence matching.

With continued reference to FIG. 4B, two depth planes 240, corresponding to different distances in space from the eyes 210, 220, are illustrated. For a given depth plane 240, vergence cues may be provided by the displaying of images of appropriately different perspectives for each eye 210, 220. In addition, for a given depth plane 240, light forming the images provided to each eye 210, 220 may have a wavefront divergence corresponding to a light field produced by a point at the distance of that depth plane 240.

In the illustrated embodiment, the distance, along the z-axis, of the depth plane 240 containing the point 221 is 1 m. As used herein, distances or depths along the z-axis may be measured with a zero-point located at the exit pupils of the user’s eyes. Thus, a depth plane 240 located at a depth of 1 m corresponds to a distance of 1 m away from the exit pupils of the user’s eyes, on the optical axis of those eyes with the eyes directed towards optical infinity. As an approximation, the depth or distance along the z-axis may be measured from the display in front of the user’s eyes (e.g., from the surface of a waveguide), plus a value for the distance between the device and the exit pupils of the user’s eyes. That value may be called the eye relief and corresponds to the distance between the exit pupil of the user’s eye and the display worn by the user in front of the eye. In practice, the value for the eye relief may be a normalized value used generally for all viewers. For example, the eye relief may be assumed to be 20 mm and a depth plane that is at a depth of 1 m may be at a distance of 980 mm in front of the display.

With reference now to FIGS. 4C and 4D, examples of matched accommodation-vergence distances and mismatched accommodation-vergence distances are illustrated, respectively. As illustrated in FIG. 4C, the display system may provide images of a virtual object to each eye 210, 220. The images may cause the eyes 210, 220 to assume a vergence state in which the eyes converge on a point 15 on

a depth plane **240**. In addition, the images may be formed by a light having a wavefront curvature corresponding to real objects at that depth plane **240**. As a result, the eyes **210**, **220** assume an accommodative state in which the images are in focus on the retinas of those eyes. Thus, the user may perceive the virtual object as being at the point **15** on the depth plane **240**.

It will be appreciated that each of the accommodative and vergence states of the eyes **210**, **220** are associated with a particular distance on the z-axis. For example, an object at a particular distance from the eyes **210**, **220** causes those eyes to assume particular accommodative states based upon the distances of the object. The distance associated with a particular accommodative state may be referred to as the accommodation distance, Ad. Similarly, there are particular vergence distances, Vd, associated with the eyes in particular vergence states, or positions relative to one another. Where the accommodation distance and the vergence distance match, the relationship between accommodation and vergence may be said to be physiologically correct. This is considered to be the most comfortable scenario for a viewer.

In stereoscopic displays, however, the accommodation distance and the vergence distance may not always match. For example, as illustrated in FIG. **4D**, images displayed to the eyes **210**, **220** may be displayed with wavefront divergence corresponding to depth plane **240**, and the eyes **210**, **220** may assume a particular accommodative state in which the points **15a**, **15b** on that depth plane are in focus. However, the images displayed to the eyes **210**, **220** may provide cues for vergence that cause the eyes **210**, **220** to converge on a point **15** that is not located on the depth plane **240**. As a result, the accommodation distance corresponds to the distance from the exit pupils of the eyes **210**, **220** to the depth plane **240**, while the vergence distance corresponds to the larger distance from the exit pupils of the eyes **210**, **220** to the point **15**, in some embodiments. The accommodation distance is different from the vergence distance. Consequently, there is an accommodation-vergence mismatch. Such a mismatch is considered undesirable and may cause discomfort in the user. It will be appreciated that the mismatch corresponds to distance (e.g., Vd-Ad) and may be characterized using diopters.

In some embodiments, it will be appreciated that a reference point other than exit pupils of the eyes **210**, **220** may be utilized for determining distance for determining accommodation-vergence mismatch, so long as the same reference point is utilized for the accommodation distance and the vergence distance. For example, the distances could be measured from the cornea to the depth plane, from the retina to the depth plane, from the eyepiece (e.g., a waveguide of the display device) to the depth plane, and so on.

Without being limited by theory, it is believed that users may still perceive accommodation-vergence mismatches of up to about 0.25 diopter, up to about 0.33 diopter, and up to about 0.5 diopter as being physiologically correct, without the mismatch itself causing significant discomfort. In some embodiments, display systems disclosed herein (e.g., the display system **250**, FIG. **6**) present images to the viewer having accommodation-vergence mismatch of about 0.5 diopter or less. In some other embodiments, the accommodation-vergence mismatch of the images provided by the display system is about 0.33 diopter or less. In yet other embodiments, the accommodation-vergence mismatch of the images provided by the display system is about 0.25 diopter or less, including about 0.1 diopter or less.

FIG. **5** illustrates aspects of an approach for simulating three-dimensional imagery by modifying wavefront diver-

gence. The display system includes a waveguide **270** that is configured to receive light **770** that is encoded with image information, and to output that light to the user's eye **210**. The waveguide **270** may output the light **650** with a defined amount of wavefront divergence corresponding to the wavefront divergence of a light field produced by a point on a desired depth plane **240**. In some embodiments, the same amount of wavefront divergence is provided for all objects presented on that depth plane. In addition, it will be illustrated that the other eye of the user may be provided with image information from a similar waveguide.

In some embodiments, a single waveguide may be configured to output light with a set amount of wavefront divergence corresponding to a single or limited number of depth planes and/or the waveguide may be configured to output light of a limited range of wavelengths. Consequently, in some embodiments, a plurality or stack of waveguides may be utilized to provide different amounts of wavefront divergence for different depth planes and/or to output light of different ranges of wavelengths. As used herein, it will be appreciated at a depth plane may be planar or may follow the contours of a curved surface.

FIG. **6** illustrates an example of a waveguide stack for outputting image information to a user. A display system **250** includes a stack of waveguides, or stacked waveguide assembly, **260** that may be utilized to provide three-dimensional perception to the eye/brain using a plurality of waveguides **270**, **280**, **290**, **300**, **310**. It will be appreciated that the display system **250** may be considered a light field display in some embodiments. In addition, the waveguide assembly **260** may also be referred to as an eyepiece.

In some embodiments, the display system **250** may be configured to provide substantially continuous cues to vergence and multiple discrete cues to accommodation. The cues to vergence may be provided by displaying different images to each of the eyes of the user, and the cues to accommodation may be provided by outputting the light that forms the images with selectable discrete amounts of wavefront divergence. Stated another way, the display system **250** may be configured to output light with variable levels of wavefront divergence. In some embodiments, each discrete level of wavefront divergence corresponds to a particular depth plane and may be provided by a particular one of the waveguides **270**, **280**, **290**, **300**, **310**.

With continued reference to FIG. **6**, the waveguide assembly **260** may also include a plurality of features **320**, **330**, **340**, **350** between the waveguides. In some embodiments, the features **320**, **330**, **340**, **350** may be one or more lenses. The waveguides **270**, **280**, **290**, **300**, **310** and/or the plurality of lenses **320**, **330**, **340**, **350** may be configured to send image information to the eye with various levels of wavefront curvature or light ray divergence. Each waveguide level may be associated with a particular depth plane and may be configured to output image information corresponding to that depth plane. Image injection devices **360**, **370**, **380**, **390**, **400** may function as a source of light for the waveguides and may be utilized to inject image information into the waveguides **270**, **280**, **290**, **300**, **310**, each of which may be configured, as described herein, to distribute incoming light across each respective waveguide, for output toward the eye **210**. Light exits an output surface **410**, **420**, **430**, **440**, **450** of the image injection devices **360**, **370**, **380**, **390**, **400** and is injected into a corresponding input surface **460**, **470**, **480**, **490**, **500** of the waveguides **270**, **280**, **290**, **300**, **310**. In some embodiments, each of the input surfaces **460**, **470**, **480**, **490**, **500** may be an edge of a corresponding waveguide, or may be part of a major surface of the

corresponding waveguide (that is, one of the waveguide surfaces directly facing the world **510** or the viewer's eye **210**). In some embodiments, a single beam of light (e.g. a collimated beam) may be injected into each waveguide to output an entire field of cloned collimated beams that are directed toward the eye **210** at particular angles (and amounts of divergence) corresponding to the depth plane associated with a particular waveguide. In some embodiments, a single one of the image injection devices **360, 370, 380, 390, 400** may be associated with and inject light into a plurality (e.g., three) of the waveguides **270, 280, 290, 300, 310**.

In some embodiments, the image injection devices **360, 370, 380, 390, 400** are discrete displays that each produce image information for injection into a corresponding waveguide **270, 280, 290, 300, 310**, respectively. In some other embodiments, the image injection devices **360, 370, 380, 390, 400** are the output ends of a single multiplexed display which may, e.g., pipe image information via one or more optical conduits (such as fiber optic cables) to each of the image injection devices **360, 370, 380, 390, 400**. It will be appreciated that the image information provided by the image injection devices **360, 370, 380, 390, 400** may include light of different wavelengths, or colors (e.g., different component colors, as discussed herein).

In some embodiments, the light injected into the waveguides **270, 280, 290, 300, 310** is provided by a light projection system **520**, which comprises a light module **530**, which may include a light emitter, such as a light emitting diode (LED). The light from the light module **530** may be directed to and modified by a light modulator **540**, e.g., a spatial light modulator, via a beam splitter **550**. The light modulator **540** may be configured to change the perceived intensity of the light injected into the waveguides **270, 280, 290, 300, 310** to encode the light with image information. Examples of spatial light modulators include liquid crystal displays (LCD) including a liquid crystal on silicon (LCOS) displays. It will be appreciated that the image injection devices **360, 370, 380, 390, 400** are illustrated schematically and, in some embodiments, these image injection devices may represent different light paths and locations in a common projection system configured to output light into associated ones of the waveguides **270, 280, 290, 300, 310**. In some embodiments, the waveguides of the waveguide assembly **260** may function as ideal lens while relaying light injected into the waveguides out to the user's eyes. In this conception, the object may be the spatial light modulator **540** and the image may be the image on the depth plane.

In some embodiments, the display system **250** may be a scanning fiber display comprising one or more scanning fibers configured to project light in various patterns (e.g., raster scan, spiral scan, Lissajous patterns, etc.) into one or more waveguides **270, 280, 290, 300, 310** and ultimately to the eye **210** of the viewer. In some embodiments, the illustrated image injection devices **360, 370, 380, 390, 400** may schematically represent a single scanning fiber or a bundle of scanning fibers configured to inject light into one or a plurality of the waveguides **270, 280, 290, 300, 310**. In some other embodiments, the illustrated image injection devices **360, 370, 380, 390, 400** may schematically represent a plurality of scanning fibers or a plurality of bundles of scanning fibers, each of which are configured to inject light into an associated one of the waveguides **270, 280, 290, 300, 310**. It will be appreciated that one or more optical fibers may be configured to transmit light from the light module **530** to the one or more waveguides **270, 280, 290, 300, 310**. It will be appreciated that one or more intervening optical

structures may be provided between the scanning fiber, or fibers, and the one or more waveguides **270, 280, 290, 300, 310** to, e.g., redirect light exiting the scanning fiber into the one or more waveguides **270, 280, 290, 300, 310**.

A controller **560** controls the operation of one or more of the stacked waveguide assembly **260**, including operation of the image injection devices **360, 370, 380, 390, 400**, the light source **530**, and the light modulator **540**. In some embodiments, the controller **560** is part of the local data processing module **140**. The controller **560** includes programming (e.g., instructions in a non-transitory medium) that regulates the timing and provision of image information to the waveguides **270, 280, 290, 300, 310** according to, e.g., any of the various schemes disclosed herein. In some embodiments, the controller may be a single integral device, or a distributed system connected by wired or wireless communication channels. The controller **560** may be part of the processing modules **140** or **150** (FIG. 9E) in some embodiments.

With continued reference to FIG. 6, the waveguides **270, 280, 290, 300, 310** may be configured to propagate light within each respective waveguide by total internal reflection (TIR). The waveguides **270, 280, 290, 300, 310** may each be planar or have another shape (e.g., curved), with major top and bottom surfaces and edges extending between those major top and bottom surfaces. In the illustrated configuration, the waveguides **270, 280, 290, 300, 310** may each include out-coupling optical elements **570, 580, 590, 600, 610** that are configured to extract light out of a waveguide by redirecting the light, propagating within each respective waveguide, out of the waveguide to output image information to the eye **210**. Extracted light may also be referred to as out-coupled light and the out-coupling optical elements may also be referred to light extracting optical elements. An extracted beam of light may be outputted by the waveguide at locations at which the light propagating in the waveguide strikes a light extracting optical element. The out-coupling optical elements **570, 580, 590, 600, 610** may, for example, be gratings, including diffractive optical features, as discussed further herein. While illustrated disposed at the bottom major surfaces of the waveguides **270, 280, 290, 300, 310**, for ease of description and drawing clarity, in some embodiments, the out-coupling optical elements **570, 580, 590, 600, 610** may be disposed at the top and/or bottom major surfaces, and/or may be disposed directly in the volume of the waveguides **270, 280, 290, 300, 310**, as discussed further herein. In some embodiments, the out-coupling optical elements **570, 580, 590, 600, 610** may be formed in a layer of material that is attached to a transparent substrate to form the waveguides **270, 280, 290, 300, 310**. In some other embodiments, the waveguides **270, 280, 290, 300, 310** may be a monolithic piece of material and the out-coupling optical elements **570, 580, 590, 600, 610** may be formed on a surface and/or in the interior of that piece of material.

With continued reference to FIG. 6, as discussed herein, each waveguide **270, 280, 290, 300, 310** is configured to output light to form an image corresponding to a particular depth plane. For example, the waveguide **270** nearest the eye may be configured to deliver collimated light (which was injected into such waveguide **270**), to the eye **210**. The collimated light may be representative of the optical infinity focal plane. The next waveguide up **280** may be configured to send out collimated light which passes through the first lens **350** (e.g., a negative lens) before it may reach the eye **210**; such first lens **350** may be configured to create a slight convex wavefront curvature so that the eye/brain interprets light coming from that next waveguide up **280** as coming

from a first focal plane closer inward toward the eye **210** from optical infinity. Similarly, the third up waveguide **290** passes its output light through both the first **350** and second **340** lenses before reaching the eye **210**; the combined optical power of the first **350** and second **340** lenses may be configured to create another incremental amount of wavefront curvature so that the eye/brain interprets light coming from the third waveguide **290** as coming from a second focal plane that is even closer inward toward the person from optical infinity than was light from the next waveguide up **280**.

The other waveguide layers **300**, **310** and lenses **330**, **320** are similarly configured, with the highest waveguide **310** in the stack sending its output through all of the lenses between it and the eye for an aggregate focal power representative of the closest focal plane to the person. To compensate for the stack of lenses **320**, **330**, **340**, **350** when viewing/interpreting light coming from the world **510** on the other side of the stacked waveguide assembly **260**, a compensating lens layer **620** may be disposed at the top of the stack to compensate for the aggregate power of the lens stack **320**, **330**, **340**, **350** below. Such a configuration provides as many perceived focal planes as there are available waveguide/lens pairings. Both the out-coupling optical elements of the waveguides and the focusing aspects of the lenses may be static (i.e., not dynamic or electro-active). In some alternative embodiments, either or both may be dynamic using electro-active features.

In some embodiments, two or more of the waveguides **270**, **280**, **290**, **300**, **310** may have the same associated depth plane. For example, multiple waveguides **270**, **280**, **290**, **300**, **310** may be configured to output images set to the same depth plane, or multiple subsets of the waveguides **270**, **280**, **290**, **300**, **310** may be configured to output images set to the same plurality of depth planes, with one set for each depth plane. This may provide advantages for forming a tiled image to provide an expanded field of view at those depth planes.

With continued reference to FIG. 6, the out-coupling optical elements **570**, **580**, **590**, **600**, **610** may be configured to both redirect light out of their respective waveguides and to output this light with the appropriate amount of divergence or collimation for a particular depth plane associated with the waveguide. As a result, waveguides having different associated depth planes may have different configurations of out-coupling optical elements **570**, **580**, **590**, **600**, **610**, which output light with a different amount of divergence depending on the associated depth plane. In some embodiments, the light extracting optical elements **570**, **580**, **590**, **600**, **610** may be volumetric or surface features, which may be configured to output light at specific angles. For example, the light extracting optical elements **570**, **580**, **590**, **600**, **610** may be volume holograms, surface holograms, and/or diffraction gratings. In some embodiments, the features **320**, **330**, **340**, **350** may not be lenses; rather, they may simply be spacers (e.g., cladding layers and/or structures for forming air gaps).

In some embodiments, the out-coupling optical elements **570**, **580**, **590**, **600**, **610** are diffractive features that form a diffraction pattern, or “diffractive optical element” (also referred to herein as a “DOE”). Preferably, the DOE’s have a sufficiently low diffraction efficiency so that only a portion of the light of the beam is deflected away toward the eye **210** with each intersection of the DOE, while the rest continues to move through a waveguide via TIR. The light carrying the image information is thus divided into a number of related exit beams that exit the waveguide at a multiplicity of

locations and the result is a fairly uniform pattern of exit emission toward the eye **210** for this particular collimated beam bouncing around within a waveguide.

In some embodiments, one or more DOEs may be switchable between “on” states in which they actively diffract, and “off” states in which they do not significantly diffract. For instance, a switchable DOE may comprise a layer of polymer dispersed liquid crystal, in which microdroplets comprise a diffraction pattern in a host medium, and the refractive index of the microdroplets may be switched to substantially match the refractive index of the host material (in which case the pattern does not appreciably diffract incident light) or the microdroplet may be switched to an index that does not match that of the host medium (in which case the pattern actively diffracts incident light).

In some embodiments, a camera assembly **630** (e.g., a digital camera, including visible light and infrared light cameras) may be provided to capture images of the eye **210** and/or tissue around the eye **210** to, e.g., detect user inputs and/or to monitor the physiological state of the user. As used herein, a camera may be any image capture device. In some embodiments, the camera assembly **630** may include an image capture device and a light source to project light (e.g., infrared light) to the eye, which may then be reflected by the eye and detected by the image capture device. In some embodiments, the camera assembly **630** may be attached to the frame **80** (FIG. 9E) and may be in electrical communication with the processing modules **140** and/or **150**, which may process image information from the camera assembly **630**. In some embodiments, one camera assembly **630** may be utilized for each eye, to separately monitor each eye.

With reference now to FIG. 7, an example of exit beams outputted by a waveguide is shown. One waveguide is illustrated, but it will be appreciated that other waveguides in the waveguide assembly **260** (FIG. 6) may function similarly, where the waveguide assembly **260** includes multiple waveguides. Light **640** is injected into the waveguide **270** at the input surface **460** of the waveguide **270** and propagates within the waveguide **270** by TIR. At points where the light **640** impinges on the DOE **570**, a portion of the light exits the waveguide as exit beams **650**. The exit beams **650** are illustrated as substantially parallel but, as discussed herein, they may also be redirected to propagate to the eye **210** at an angle (e.g., forming divergent exit beams), depending on the depth plane associated with the waveguide **270**. It will be appreciated that substantially parallel exit beams may be indicative of a waveguide with out-coupling optical elements that out-couple light to form images that appear to be set on a depth plane at a large distance (e.g., optical infinity) from the eye **210**. Other waveguides or other sets of out-coupling optical elements may output an exit beam pattern that is more divergent, which would require the eye **210** to accommodate to a closer distance to bring it into focus on the retina and would be interpreted by the brain as light from a distance closer to the eye **210** than optical infinity.

In some embodiments, a full color image may be formed at each depth plane by overlaying images in each of the component colors, e.g., three or more component colors. FIG. 8 illustrates an example of a stacked waveguide assembly in which each depth plane includes images formed using multiple different component colors. The illustrated embodiment shows depth planes **240a**—**240f**, although more or fewer depths are also contemplated. Each depth plane may have three or more component color images associated with it, including: a first image of a first color, G; a second image of a second color, R; and a third image of a third color, B.

Different depth planes are indicated in the figure by different numbers for diopters (dpt) following the letters G, R, and B. Just as examples, the numbers following each of these letters indicate diopters (1/m), or inverse distance of the depth plane from a viewer, and each box in the figures represents an individual component color image. In some embodiments, to account for differences in the eye's focusing of light of different wavelengths, the exact placement of the depth planes for different component colors may vary. For example, different component color images for a given depth plane may be placed on depth planes corresponding to different distances from the user. Such an arrangement may increase visual acuity and user comfort and/or may decrease chromatic aberrations.

In some embodiments, light of each component color may be outputted by a single dedicated waveguide and, consequently, each depth plane may have multiple waveguides associated with it. In such embodiments, each box in the figures including the letters G, R, or B may be understood to represent an individual waveguide, and three waveguides may be provided per depth plane where three component color images are provided per depth plane. While the waveguides associated with each depth plane are shown adjacent to one another in this drawing for ease of description, it will be appreciated that, in a physical device, the waveguides may all be arranged in a stack with one waveguide per level. In some other embodiments, multiple component colors may be outputted by the same waveguide, such that, e.g., only a single waveguide may be provided per depth plane.

With continued reference to FIG. 8, in some embodiments, G is the color green, R is the color red, and B is the color blue. In some other embodiments, other colors associated with other wavelengths of light, including magenta and cyan, may be used in addition to or may replace one or more of red, green, or blue.

It will be appreciated that references to a given color of light throughout this disclosure will be understood to encompass light of one or more wavelengths within a range of wavelengths of light that are perceived by a viewer as being of that given color. For example, red light may include light of one or more wavelengths in the range of about 620-780 nm, green light may include light of one or more wavelengths in the range of about 492-577 nm, and blue light may include light of one or more wavelengths in the range of about 435-493 nm.

In some embodiments, the light source 530 (FIG. 6) may be configured to emit light of one or more wavelengths outside the visual perception range of the viewer, for example, infrared and/or ultraviolet wavelengths. In addition, the in-coupling, out-coupling, and other light redirecting structures of the waveguides of the display 250 may be configured to direct and emit this light out of the display towards the user's eye 210, e.g., for imaging and/or user stimulation applications.

With reference now to FIG. 9A, in some embodiments, light impinging on a waveguide may need to be redirected to in-couple that light into the waveguide. An in-coupling optical element may be used to redirect and in-couple the light into its corresponding waveguide. FIG. 9A illustrates a cross-sectional side view of an example of a plurality or set 660 of stacked waveguides that each includes an in-coupling optical element. The waveguides may each be configured to output light of one or more different wavelengths, or one or more different ranges of wavelengths. It will be appreciated that the stack 660 may correspond to the stack 260 (FIG. 6) and the illustrated waveguides of the stack 660 may corre-

spond to part of the plurality of waveguides 270, 280, 290, 300, 310, except that light from one or more of the image injection devices 360, 370, 380, 390, 400 is injected into the waveguides from a position that requires light to be redirected for in-coupling.

The illustrated set 660 of stacked waveguides includes waveguides 670, 680, and 690. Each waveguide includes an associated in-coupling optical element (which may also be referred to as a light input area on the waveguide), with, e.g., in-coupling optical element 700 disposed on a major surface (e.g., an upper major surface) of waveguide 670, in-coupling optical element 710 disposed on a major surface (e.g., an upper major surface) of waveguide 680, and in-coupling optical element 720 disposed on a major surface (e.g., an upper major surface) of waveguide 690. In some embodiments, one or more of the in-coupling optical elements 700, 710, 720 may be disposed on the bottom major surface of the respective waveguide 670, 680, 690 (particularly where the one or more in-coupling optical elements are reflective, deflecting optical elements). As illustrated, the in-coupling optical elements 700, 710, 720 may be disposed on the upper major surface of their respective waveguide 670, 680, 690 (or the top of the next lower waveguide), particularly where those in-coupling optical elements are transmissive, deflecting optical elements. In some embodiments, the in-coupling optical elements 700, 710, 720 may be disposed in the body of the respective waveguide 670, 680, 690. In some embodiments, as discussed herein, the in-coupling optical elements 700, 710, 720 are wavelength selective, such that they selectively redirect one or more wavelengths of light, while transmitting other wavelengths of light. While illustrated on one side or corner of their respective waveguide 670, 680, 690, it will be appreciated that the in-coupling optical elements 700, 710, 720 may be disposed in other areas of their respective waveguide 670, 680, 690 in some embodiments.

As illustrated, the in-coupling optical elements 700, 710, 720 may be laterally offset from one another, as seen in the illustrated head-on view in a direction of light propagating to these in-coupling optical elements. In some embodiments, each in-coupling optical element may be offset such that it receives light without that light passing through another in-coupling optical element. For example, each in-coupling optical element 700, 710, 720 may be configured to receive light from a different image injection device 360, 370, 380, 390, and 400 as shown in FIG. 6, and may be separated (e.g., laterally spaced apart) from other in-coupling optical elements 700, 710, 720 such that it substantially does not receive light from the other ones of the in-coupling optical elements 700, 710, 720.

Each waveguide also includes associated light distributing elements, with, e.g., light distributing elements 730 disposed on a major surface (e.g., a top major surface) of waveguide 670, light distributing elements 740 disposed on a major surface (e.g., a top major surface) of waveguide 680, and light distributing elements 750 disposed on a major surface (e.g., a top major surface) of waveguide 690. In some other embodiments, the light distributing elements 730, 740, 750, may be disposed on a bottom major surface of associated waveguides 670, 680, 690, respectively. In some other embodiments, the light distributing elements 730, 740, 750, may be disposed on both top and bottom major surface of associated waveguides 670, 680, 690, respectively; or the light distributing elements 730, 740, 750, may be disposed on different ones of the top and bottom major surfaces in different associated waveguides 670, 680, 690, respectively.

The waveguides **670**, **680**, **690** may be spaced apart and separated by, e.g., gas, liquid, and/or solid layers of material. For example, as illustrated, layer **760a** may separate waveguides **670** and **680**; and layer **760b** may separate waveguides **680** and **690**. In some embodiments, the layers **760a** and **760b** are formed of low refractive index materials (that is, materials having a lower refractive index than the material forming the immediately adjacent one of waveguides **670**, **680**, **690**). Preferably, the refractive index of the material forming the layers **760a**, **760b** is 0.05 or more, or 0.10 or less than the refractive index of the material forming the waveguides **670**, **680**, **690**. Advantageously, the lower refractive index layers **760a**, **760b** may function as cladding layers that facilitate total internal reflection (TIR) of light through the waveguides **670**, **680**, **690** (e.g., TIR between the top and bottom major surfaces of each waveguide). In some embodiments, the layers **760a**, **760b** are formed of air. While not illustrated, it will be appreciated that the top and bottom of the illustrated set **660** of waveguides may include immediately neighboring cladding layers.

Preferably, for ease of manufacturing and other considerations, the material forming the waveguides **670**, **680**, **690** are similar or the same, and the material forming the layers **760a**, **760b** are similar or the same. In some embodiments, the material forming the waveguides **670**, **680**, **690** may be different between one or more waveguides, and/or the material forming the layers **760a**, **760b** may be different, while still holding to the various refractive index relationships noted above.

With continued reference to FIG. 9A, light rays **770**, **780**, **790** are incident on the set **660** of waveguides. It will be appreciated that the light rays **770**, **780**, **790** may be injected into the waveguides **670**, **680**, **690** by one or more image injection devices **360**, **370**, **380**, **390**, **400** (FIG. 6).

In some embodiments, the light rays **770**, **780**, **790** have different properties, e.g., different wavelengths or different ranges of wavelengths, which may correspond to different colors. The in-coupling optical elements **700**, **710**, **720** each deflect the incident light such that the light propagates through a respective one of the waveguides **670**, **680**, **690** by TIR. In some embodiments, the in-coupling optical elements **700**, **710**, **720** each selectively deflect one or more particular wavelengths of light, while transmitting other wavelengths to an underlying waveguide and associated in-coupling optical element.

For example, in-coupling optical element **700** may be configured to deflect ray **770**, which has a first wavelength or range of wavelengths, while transmitting rays **780** and **790**, which have different second and third wavelengths or ranges of wavelengths, respectively. The transmitted ray **780** impinges on and is deflected by the in-coupling optical element **710**, which is configured to deflect light of a second wavelength or range of wavelengths. The ray **790** is deflected by the in-coupling optical element **720**, which is configured to selectively deflect light of third wavelength or range of wavelengths.

With continued reference to FIG. 9A, the deflected light rays **770**, **780**, **790** are deflected so that they propagate through a corresponding waveguide **670**, **680**, **690**; that is, the in-coupling optical elements **700**, **710**, **720** of each waveguide deflects light into that corresponding waveguide **670**, **680**, **690** to in-couple light into that corresponding waveguide. The light rays **770**, **780**, **790** are deflected at angles that cause the light to propagate through the respective waveguide **670**, **680**, **690** by TIR. The light rays **770**, **780**, **790** propagate through the respective waveguide **670**,

680, **690** by TIR until impinging on the waveguide's corresponding light distributing elements **730**, **740**, **750**.

With reference now to FIG. 9B, a perspective view of an example of the plurality of stacked waveguides of FIG. 9A is illustrated. As noted above, the in-coupled light rays **770**, **780**, **790**, are deflected by the in-coupling optical elements **700**, **710**, **720**, respectively, and then propagate by TIR within the waveguides **670**, **680**, **690**, respectively. The light rays **770**, **780**, **790** then impinge on the light distributing elements **730**, **740**, **750**, respectively. The light distributing elements **730**, **740**, **750** deflect the light rays **770**, **780**, **790** so that they propagate towards the out-coupling optical elements **800**, **810**, **820**, respectively.

In some embodiments, the light distributing elements **730**, **740**, **750** are orthogonal pupil expanders (OPE's). In some embodiments, the OPE's deflect or distribute light to the out-coupling optical elements **800**, **810**, **820** and, in some embodiments, may also increase the beam or spot size of this light as it propagates to the out-coupling optical elements. In some embodiments, the light distributing elements **730**, **740**, **750** may be omitted and the in-coupling optical elements **700**, **710**, **720** may be configured to deflect light directly to the out-coupling optical elements **800**, **810**, **820**. For example, with reference to FIG. 9A, the light distributing elements **730**, **740**, **750** may be replaced with out-coupling optical elements **800**, **810**, **820**, respectively. In some embodiments, the out-coupling optical elements **800**, **810**, **820** are exit pupils (EP's) or exit pupil expanders (EPE's) that direct light in a viewer's eye **210** (FIG. 7). It will be appreciated that the OPE's may be configured to increase the dimensions of the eye box in at least one axis and the EPE's may be to increase the eye box in an axis crossing, e.g., orthogonal to, the axis of the OPEs. For example, each OPE may be configured to redirect a portion of the light striking the OPE to an EPE of the same waveguide, while allowing the remaining portion of the light to continue to propagate down the waveguide. Upon impinging on the OPE again, another portion of the remaining light is redirected to the EPE, and the remaining portion of that portion continues to propagate further down the waveguide, and so on. Similarly, upon striking the EPE, a portion of the impinging light is directed out of the waveguide towards the user, and a remaining portion of that light continues to propagate through the waveguide until it strikes the EP again, at which time another portion of the impinging light is directed out of the waveguide, and so on. Consequently, a single beam of in-coupled light may be "replicated" each time a portion of that light is redirected by an OPE or EPE, thereby forming a field of cloned beams of light, as shown in FIG. 6. In some embodiments, the OPE and/or EPE may be configured to modify a size of the beams of light.

Accordingly, with reference to FIGS. 9A and 9B, in some embodiments, the set **660** of waveguides includes waveguides **670**, **680**, **690**; in-coupling optical elements **700**, **710**, **720**; light distributing elements (e.g., OPE's) **730**, **740**, **750**; and out-coupling optical elements (e.g., EP's) **800**, **810**, **820** for each component color. The waveguides **670**, **680**, **690** may be stacked with an air gap/cladding layer between each one. The in-coupling optical elements **700**, **710**, **720** redirect or deflect incident light (with different in-coupling optical elements receiving light of different wavelengths) into its waveguide. The light then propagates at an angle which will result in TIR within the respective waveguide **670**, **680**, **690**. In the example shown, light ray **770** (e.g., blue light) is deflected by the first in-coupling optical element **700**, and then continues to bounce down the waveguide, interacting with the light distributing element (e.g., OPE's) **730** and

then the out-coupling optical element (e.g., EPs) **800**, in a manner described earlier. The light rays **780** and **790** (e.g., green and red light, respectively) will pass through the waveguide **670**, with light ray **780** impinging on and being deflected by in-coupling optical element **710**. The light ray **780** then bounces down the waveguide **680** via TIR, proceeding on to its light distributing element (e.g., OPEs) **740** and then the out-coupling optical element (e.g., EP's) **810**. Finally, light ray **790** (e.g., red light) passes through the waveguide **690** to impinge on the light in-coupling optical elements **720** of the waveguide **690**. The light in-coupling optical elements **720** deflect the light ray **790** such that the light ray propagates to light distributing element (e.g., OPEs) **750** by TIR, and then to the out-coupling optical element (e.g., EPs) **820** by TIR. The out-coupling optical element **820** then finally out-couples the light ray **790** to the viewer, who also receives the out-coupled light from the other waveguides **670**, **680**.

FIG. 9C illustrates a top-down plan view of an example of the plurality of stacked waveguides of FIGS. 9A and 9B. It will be appreciated that this top-down view may also be referred to as a head-on view, as seen in the direction of propagation of light towards the in-coupling optical elements **800**, **810**, **820**; that is, the top-down view is a view of the waveguides with image light incident normal to the page. As illustrated, the waveguides **670**, **680**, **690**, along with each waveguide's associated light distributing element **730**, **740**, **750** and associated out-coupling optical element **800**, **810**, **820**, may be vertically aligned. However, as discussed herein, the in-coupling optical elements **700**, **710**, **720** are not vertically aligned; rather, the in-coupling optical elements are preferably non-overlapping (e.g., laterally spaced apart as seen in the top-down view). As discussed further herein, this nonoverlapping spatial arrangement facilitates the injection of light from different sources into different waveguides on a one-to-one basis, thereby allowing a specific light source to be uniquely coupled to a specific waveguide. In some embodiments, arrangements including nonoverlapping spatially-separated in-coupling optical elements may be referred to as a shifted pupil system, and the in-coupling optical elements within these arrangements may correspond to sub-pupils.

It will be appreciated that the spatially overlapping areas may have lateral overlap of 70% or more, 80% or more, or 90% or more of their areas, as seen in the top-down view. On the other hand, the laterally shifted areas of less than 30% overlap, less than 20% overlap, or less than 10% overlap of their areas, as seen in top-down view. In some embodiments, laterally shifted areas have no overlap.

FIG. 9D illustrates a top-down plan view of another example of a plurality of stacked waveguides. As illustrated, the waveguides **670**, **680**, **690** may be vertically aligned. However, in comparison to the configuration of FIG. 9C, separate light distributing elements **730**, **740**, **750** and associated out-coupling optical elements **800**, **810**, **820** are omitted. Instead, light distributing elements and out-coupling optical elements are effectively superimposed and occupy the same area as seen in the top-down view. In some embodiments, light distributing elements (e.g., OPE's) may be disposed on one major surface of the waveguides **670**, **680**, **690** and out-coupling optical elements (e.g., EPE's) may be disposed on the other major surface of those waveguides. Thus, each waveguide **670**, **680**, **690** may have superimposed light distributing and out coupling optical elements, collectively referred to as combined OPE/EPE's **1281**, **1282**, **1283**, respectively. Further details regarding such combined OPE/EPE's may be found in U.S. applica-

tion Ser. No. 16/221,359, filed on Dec. 14, 2018, the entire disclosure of which is incorporated by reference herein. The in-coupling optical elements **700**, **710**, **720** in-couple and direct light to the combined OPE/EPE's **1281**, **1282**, **1283**, respectively. In some embodiments, as illustrated, the in-coupling optical elements **700**, **710**, **720** may be laterally shifted (e.g., they are laterally spaced apart as seen in the illustrated top-down view) in have a shifted pupil spatial arrangement. As with the configuration of FIG. 9C, this laterally-shifted spatial arrangement facilitates the injection of light of different wavelengths (e.g., from different light sources) into different waveguides on a one-to-one basis.

FIG. 9E illustrates an example of wearable display system **60** into which the various waveguides and related systems disclosed herein may be integrated. In some embodiments, the display system **60** is the system **250** of FIG. 6, with FIG. 6 schematically showing some parts of that system **60** in greater detail. For example, the waveguide assembly **260** of FIG. 6 may be part of the display **70**.

With continued reference to FIG. 9E, the display system **60** includes a display **70**, and various mechanical and electronic modules and systems to support the functioning of that display **70**. The display **70** may be coupled to a frame **80**, which is wearable by a display system user or viewer **90** and which is configured to position the display **70** in front of the eyes of the user **90**. The display **70** may be considered eyewear in some embodiments. The display **70** may include one or more waveguides, such as the waveguide **270**, configured to relay in-coupled image light and to output that image light to an eye of the user **90**. In some embodiments, a speaker **100** is coupled to the frame **80** and configured to be positioned adjacent the ear canal of the user **90** (in some embodiments, another speaker, not shown, may optionally be positioned adjacent the other ear canal of the user to provide stereo/shapeable sound control). The display system **60** may also include one or more microphones **110** or other devices to detect sound. In some embodiments, the microphone is configured to allow the user to provide inputs or commands to the system **60** (e.g., the selection of voice menu commands, natural language questions, etc.), and/or may allow audio communication with other persons (e.g., with other users of similar display systems). The microphone may further be configured as a peripheral sensor to collect audio data (e.g., sounds from the user and/or environment). In some embodiments, the display system **60** may further include one or more outwardly-directed environmental sensors **112** configured to detect objects, stimuli, people, animals, locations, or other aspects of the world around the user. For example, environmental sensors **112** may include one or more cameras, which may be located, for example, facing outward so as to capture images similar to at least a portion of an ordinary field of view of the user **90**. In some embodiments, the display system may also include a peripheral sensor **120a**, which may be separate from the frame **80** and attached to the body of the user **90** (e.g., on the head, torso, an extremity, etc. of the user **90**). The peripheral sensor **120a** may be configured to acquire data characterizing a physiological state of the user **90** in some embodiments. For example, the sensor **120a** may be an electrode.

With continued reference to FIG. 9E, the display **70** is operatively coupled by communications link **130**, such as by a wired lead or wireless connectivity, to a local data processing module **140** which may be mounted in a variety of configurations, such as fixedly attached to the frame **80**, fixedly attached to a helmet or hat worn by the user, embedded in headphones, or otherwise removably attached to the user **90** (e.g., in a backpack-style configuration, in a

belt-coupling style configuration). Similarly, the sensor **120a** may be operatively coupled by communications link **120b**, e.g., a wired lead or wireless connectivity, to the local processor and data module **140**. The local processing and data module **140** may comprise a hardware processor, as well as digital memory, such as non-volatile memory (e.g., flash memory or hard disk drives), both of which may be utilized to assist in the processing, caching, and storage of data. Optionally, the local processor and data module **140** may include one or more central processing units (CPUs), graphics processing units (GPUs), dedicated processing hardware, and so on. The data may include data a) captured from sensors (which may be, e.g., operatively coupled to the frame **80** or otherwise attached to the user **90**), such as image capture devices (such as cameras), microphones, inertial measurement units, accelerometers, compasses, GPS units, radio devices, gyros, and/or other sensors disclosed herein; and/or b) acquired and/or processed using remote processing module **150** and/or remote data repository **160** (including data relating to virtual content), possibly for passage to the display **70** after such processing or retrieval. The local processing and data module **140** may be operatively coupled by communication links **170**, **180**, such as via a wired or wireless communication links, to the remote processing module **150** and remote data repository **160** such that these remote modules **150**, **160** are operatively coupled to each other and available as resources to the local processing and data module **140**. In some embodiments, the local processing and data module **140** may include one or more of the image capture devices, microphones, inertial measurement units, accelerometers, compasses, GPS units, radio devices, and/or gyros. In some other embodiments, one or more of these sensors may be attached to the frame **80**, or may be standalone structures that communicate with the local processing and data module **140** by wired or wireless communication pathways.

With continued reference to FIG. 9E, in some embodiments, the remote processing module **150** may comprise one or more processors configured to analyze and process data and/or image information, for instance including one or more central processing units (CPUs), graphics processing units (GPUs), dedicated processing hardware, and so on. In some embodiments, the remote data repository **160** may comprise a digital data storage facility, which may be available through the internet or other networking configuration in a “cloud” resource configuration. In some embodiments, the remote data repository **160** may include one or more remote servers, which provide information, e.g., information for generating virtual content, to the local processing and data module **140** and/or the remote processing module **150**. In some embodiments, all data is stored and all computations are performed in the local processing and data module, allowing fully autonomous use from a remote module. Optionally, an outside system (e.g., a system of one or more processors, one or more computers) that includes CPUs, GPUs, and so on, may perform at least a portion of processing (e.g., generating image information, processing data) and provide information to, and receive information from, modules **140**, **150**, **160**, for instance via wireless or wired connections.

FIG. 10 illustrates an example of a wearable display system with a light projection system **910** having a spatial light modulator **930** and a separate light source **940**. The light source **940** may comprise one or more light emitters and illuminates the spatial light modulator (SLM) **930**. A lens structure **960** may be used to focus the light from the light source **940** onto the SLM **930**. A beam splitter (e.g., a

polarizing beam splitter (PBS)) **950** reflects light from the light source **940** to the spatial light modulator **930**, which reflects and modulates the light. The reflected modulated light, also referred to as image light, then propagates through the beam splitter **950** to the eyepiece **920**. Another lens structure, projection optics **970**, may be utilized to converge or focus the image light onto the eyepiece **920**. The eyepiece **920** may include one or more waveguides or waveguides that relay the modulated to the eye **210**.

As noted herein, the separate light source **940** and associated lens structure **960** may undesirably add weight and size to the wearable display system. This may decrease the comfort of the display system, particularly for a user wearing the display system for an extended duration.

In addition, the light source **940** in conjunction with the SLM **930** may consume energy inefficiently. For example, the light source **940** may illuminate the entirety of the SLM **930**. The SLM **930** then selectively reflects light towards the eyepiece **920**. Thus, not all the light produced by the light source **940** may be utilized to form an image; some of this light, e.g., light corresponding to dark regions of an image, is not reflected to the eyepiece **920**. As a result, the light source **940** utilizes energy to generate light to illuminate the entirety of the SLM **930**, but only a fraction of this light may be needed to form some images.

Moreover, as noted herein, in some cases, the SLM **930** may modulate light using a micro-mirror to selectively reflect incident light, or using liquid crystal molecules that modify the amount of light reflected from an underlying mirror. As a result, such devices require physical movement of optical elements (e.g., micro-mirrors or liquid crystal molecules) in order to modulate light from the light source **940**. The physical movement required to modulate light to encode the light with image information, e.g., corresponding to a pixel, may occur at relatively slow speeds in comparison to, e.g., the ability to turn an LED or OLED “on” or “off”. This relatively slow movement may limit the frame rate of the display system and may be visible as, e.g., motion blur, color-breakup, and/or presented images that are mismatched with the pose of the user’s head or changes in said pose.

Advantageously, wearable displays utilizing emissive micro-displays, as disclosed herein, may facilitate wearable display systems that have a relatively low weight and bulkiness, high energy efficiency, and high frame rate, with low motion blur and low motion-to-photon latency. Low blur and low motion-to-photon latency are further discussed in U.S. Provisional Application No. 62/786,199, filed Dec. 28, 2018, the entire disclosure of which is incorporated by reference herein. In addition, in comparison to scanning fiber displays, the emissive micro-displays may avoid artifacts caused by the use of coherent light sources.

With reference now to FIG. 11A, an example is illustrated of a wearable display system with a light projection system **1010** having multiple emissive micro-displays **1030a**, **1030b**, **1030c**. Light from the micro-displays **1030a**, **1030b**, **1030c** is combined by an optical combiner **1050** and directed towards an eyepiece **1020**, which relays the light to the eye **210** of a user. Projection optics **1070** may be provided between the optical combiner **1050** and the eyepiece **1020**. In some embodiments, the eyepiece **1020** may be a waveguide assembly comprising one or more waveguides. In some embodiments, the light projection system **1010** and the eyepiece **1020** may be supported (e.g., attached to) the frame **80** (FIG. 9E).

In some embodiments, the micro-displays **1030a**, **1030b**, **1030c** may be monochrome micro-displays, with each monochrome micro-display outputting light of a different

component color to provide a monochrome image. As discussed herein, the monochrome images combine to form a full-color image.

In some other embodiments, the micro-displays **1030a**, **1030b**, **1030c** may be may each be full-color displays configured to output light of all component colors. For example, the micro-displays **1030a**, **1030b**, **1030c** each include red, green, and blue light emitters. The micro-displays **1030a**, **1030b**, **1030c** may be identical and may display the same image. However, utilizing multiple micro-displays may provide advantages for increasing the brightness and brightness dynamic range of the brightness of the image, by combining the light from the multiple micro-displays to form a single image. In some embodiments, two or more (e.g., three) micro-displays may be utilized, with the optical combiner **1050** is configured to combine light from all of these micro-displays.

The micro-displays may comprise an array of light emitters. Examples of light emitters include organic light-emitting diodes (OLEDs) and micro-light-emitting diodes (micro-LEDs). It will be appreciated that OLEDs utilize organic material to emit light and micro-LEDs utilize inorganic material to emit light. Advantageously, some micro-LEDs provide higher luminance and higher efficiency (in terms of lux/W) than OLEDs. In some embodiments, the micro-displays are preferably micro-LED displays.

With continued reference to FIG. 11A, the micro-displays **1030a**, **1030b**, **1030c** may each be configured to emit image light **1032a**, **1032b**, **1032c**. Where the micro-displays are monochrome micro-displays, the image light **1032a**, **1032b**, **1032c** may each be of a different component color. The optical combiner **1050** receives the image light **1032a**, **1032b**, **1032c** and effectively combines this light such that the light propagates generally in the same direction, e.g., toward the projection optics **1070**. In some embodiments, the optical combiner **1050** may be a dichroic X-cube prism having reflective internal surfaces that redirect the image light **1032a**, **1032b**, **1032c** to the projection optics **1070**. It will be appreciated that the projection optics **1070** may be a lens structure comprising one or more lenses which converge or focus image light onto the eyepiece **1020**. The eyepiece **1020** then relays the image light **1032a**, **1032b**, **1032c** to the eye **210**.

In some embodiments, the eyepiece **1020** may comprise a plurality of stacked waveguides **1020a**, **1020b**, **1020c**, each of which has a respective in-coupling optical element **1022a**, **1022b**, **1022c**. In some embodiments, the number of waveguides is proportional to the number of component colors provided by the micro-displays **1030a**, **1030b**, **1030c**. For example, where there are three component colors, the number of waveguides in the eyepiece **1020** may include a set of three waveguides or multiple sets of three waveguides each. In some embodiments, each set may output light with wavefront divergence corresponding to a particular depth plane, as discussed herein. It will be appreciated that the waveguides **1020a**, **1020b**, **1020c** and the in-coupling optical element **1022a**, **1022b**, **1022c** may correspond to the waveguides **670**, **680**, **690** and the in-coupling optical elements **700**, **710**, **720**, respectively, of FIGS. 9A-9C. As viewed from the projection optics **1070**, the in-coupling optical elements **1022a**, **1022b**, **1022c** may be laterally shifted, such that they at least partly do not overlap as seen in such a view.

As illustrated, the various in-coupling optical elements disclosed herein (e.g., the in-coupling optical element **1022a**, **1022b**, **1022c**) may be disposed on a major surface of an associated waveguide (e.g., waveguides **1020a**, **1020b**,

1020c, respectively). In addition, as also illustrated, the major surface on which a given in-coupling optical element is disposed may be the rear surface of the waveguide. In such a configuration, the in-coupling optical element may be a reflective light redirecting element, which in-couples light by reflecting the light at angles which support TIR through the associated waveguide. In some other configurations, the in-coupling optical element may be disposed on the forward surface of the waveguide (closer to the projection optics **1070** than the rearward surface). In such configurations, the in-coupling optical element may be a transmissive light redirecting element, which in-couples light by changing the direction of propagation of light as the light is transmitted through the in-coupling optical element. It will be appreciated that any of the in-coupling optical elements disclosed herein may be reflective or transmissive in-coupling optical elements.

With continued reference to FIG. 11A, image light **1032a**, **1032b**, **1032c** from different ones of the micro-displays **1030a**, **1030b**, **1030c** may take different paths to the eyepiece **1020**, such that they impinge on different ones of the in-coupling optical element **1022a**, **1022b**, **1022c**. Where the image light **1032a**, **1032b**, **1032c** includes light of different component colors, the associated in-coupling optical element **1022a**, **1022b**, **1022c**, respectively, may be configured to selectively in couple light of different wavelengths, as discussed above regarding, e.g., the in-coupling optical elements **700**, **710**, **720** of FIGS. 9A-9C.

With continued reference to FIG. 11A, the optical combiner **1050** may be configured to redirect the image light **1032a**, **1032b**, **1032c** emitted by the micro-displays **1030a**, **1030b**, **1030c** such that the image light propagates along different optical paths, in order to impinge on the appropriate associated one of the in-coupling optical element **1022a**, **1022b**, **1022c**. Thus, the optical combiner **1050** combines the image light **1032a**, **1032b**, **1032c** in the sense that the image light is outputted from a common face of the optical combiner **1050**, although light may exit the optical combiner in slightly different directions. For example, the reflective internal surfaces **1052**, **1054** of the X-cube prism may each be angled to direct the image light **1032a**, **1032b**, **1032c** along different paths to the eyepiece **1020**. As a result, the image light **1032a**, **1032b**, **1032c** may be incident on different associated ones of in-coupling optical elements **1022a**, **1022b**, **1022c**. In some embodiments, the micro-displays **1030a**, **1030b**, **1030c** may be appropriately angled relative to the reflective internal surfaces **1052**, **1054** of the X-cube prism to provide the desired light paths to the in-coupling optical elements **1022a**, **1022b**, **1022c**. For example, faces of one or more of the micro-displays **1030a**, **1030b**, **1030c** may be angled to matching faces of the optical combiner **1050**, such that image light emitted by the micro-displays is incident on the reflective internal surfaces **1052**, **1054** at an appropriate angle to propagate towards the associated in coupling optical element **1022a**, **1022b**, or **1022c**. It will be appreciated that, in addition to a cube, the optical combiner **1050** may take the form of various other polyhedra. For example, the optical combiner **1050** may be in the shape of a rectangular prism having at least two faces that are not squares.

With continued reference to FIG. 11A, in some embodiments, the monochrome micro-display **1030b** directly opposite the output face **1051** may advantageously output green light. It will be appreciated that the reflective surfaces **1052**, **1054** may have optical losses when reflecting light from the micro-displays. In addition, the human eye is most sensitive to the color green. Consequently, the monochrome micro-

display **1030b** opposite the output face **1051** preferably outputs green light, so that the green light may proceed directly through the optical combiner **1050** without needing to be reflected to be outputted from the optical combiner **1050**. It will be appreciated, however, that the green monochrome micro-display may face other surfaces of the optical combiner **1050** in some other embodiments.

As discussed herein, the perception of a full color image by a user may be achieved with time division multiplexing in some embodiments. For example, different ones of the emissive micro-displays **1030a**, **1030b**, **1030c** may be activated at different times to generate different component color images.

In such embodiments, the different component color images that form a single full color image may be sequentially displayed sufficiently quickly that the human visual system does not perceive the component color images as being displayed at different times; that is, the different component color images that form a single full color image may all be displayed within a duration that is sufficiently short that the user perceives the component color images as being simultaneously presented, rather than being temporally separated. For example, it will be appreciated that the human visual system may have a flicker fusion threshold. The flicker fusion threshold may be understood to a duration within which the human visual system is unable to differentiate images as being presented at different times. Images presented within that duration are fused or combined and, as a result, may be perceived by a user to be present simultaneously. Flickering images with temporal gaps between the images that are outside of that duration are not combined, and the flickering of the images is perceptible. In some embodiments, the duration is $\frac{1}{60}$ seconds or less, which corresponds to a frame rate of 60 Hz or more. Preferably, image frames for any individual eye are provided to the user at a frame rate equal to or higher than the duration of the flicker fusion threshold of the user. For example, the frame rate for each of the left-eye or right-eye pieces may be 60 Hz or more, or 120 Hz or more; and, as a result, the frame rate provided by the light projection system **1010** may be 120 Hz or more, or 240 Hz or more in some embodiments.

It will be appreciated that time division multiplexing may advantageously reduce the computational load on processors (e.g., graphics processors) utilized to form displayed images. In some other embodiments, such as where sufficient computational resources are available, all component color images that form a full color image may be displayed simultaneously by the micro-displays **1030a**, **1030b**, **1030c**.

As discussed herein, the micro-displays **1030a**, **1030b**, **1030c** may each include arrays of light emitters. FIG. **11B** illustrates an example of an array **1042** of light emitters **1044**. Where the associated micro-display is a monochrome micro-display, the light emitters **1044** may all be configured to emit light of the same color.

Where the associated micro-display is a full-color micro-display, different ones of the light emitters **1044** may be configured to emit light of different colors. In such embodiments, the light emitters **1044** may be considered subpixels and may be arranged in groups, with each group having at least one light emitter configured to emit light of each component color. For example, where the component colors are red, green, and blue, each group may have at least one red subpixel, at least one green subpixel, in at least one blue subpixel.

It will be appreciated, that while the light emitters **1044** are shown arranged in a grid pattern for ease of illustration, the light emitters **1044** may have other regularly repeating

spatial arrangements. For example, the number of light emitters of different component colors may vary, the sizes of the light emitters may vary, the shapes of the light emitters and/or the shapes made out by groups of light emitters may vary, etc.

With continued reference to FIG. **11B**, it will be appreciated that the micro-emitters **1044** emit light. In addition, manufacturing constraints, such as lithography or other patterning and processing limitations, and/or electrical considerations, may limit how closely neighboring light-emitters **1044** are spaced. As a result, there may be an area **1045** surrounding the light-emitting emitter **1044** within which it is not practical to form other light emitters **1044**. This area **1045** forms the inter-emitter regions between light emitters **1044**. In some embodiments, taking into account the area **1045**, the light emitters have a pitch of, e.g., less than 10 μm , less than 8 μm , less than 6 μm , or less than 5 μm , and more than 1 μm , including 1-5 μm , and an emitter size of 2 μm or less, 1.7 μm or less, or 1.3 μm or less. In some embodiments, the emitter size is within a range having an upper limit of the above-noted sizes and a lower limit of 1 μm . In some embodiments, the ratio of emitter size to pitch is 1:1 to 1:5, 1:2 to 1:4, or 1:2 to 1:3.

It will be appreciated that, given some light emitter device architectures and materials, current crowding may decrease the emitter's efficiency and pixel droop may cause unintentional activation of pixels (e.g., due to energy directed to one light emitter bleeding into a neighboring light emitter). As a result, a relatively large area **1045** may beneficially reduce current crowding and pixel droop. In some embodiments, the ratio of emitter size to pitch is preferably 1:2 to 1:4, or 1:2 to 1:3.

It will also be appreciated, however, that large separations between light emitters (e.g., a small light emitter to pitch ratio) may undesirably cause visible gaps, or dark regions, between the light emitters. In some embodiments, lens structure such as light collimators may be utilized to effectively fill in these dark regions. For example, a light collimating lens may extend on and around a light emitter **1044**, such that light from the emitter **1044** completely fills the lens. For example, the light collimating lens may have a larger width than the light emitters **1044** and, in some embodiments, the width of the collimating lens may be approximately equal to the pitch. As a result, the size of the emitter **1044** is effectively increased to extend across the area of the lens, thereby filling in some or all of the area **1045**. Lens structures such as light collimators are further discussed herein (e.g., in FIG. **30A** and the related discussion).

As discussed herein, the light emitters **1044** may be OLEDs or micro-LEDs. It will be appreciated that OLEDs may utilize layers of organic material, e.g., disposed between electrodes, to emit light. Micro-LEDs may utilize inorganic materials, e.g., Group III-V materials such as GaAs, GaN, and/or GaIn for light emission. Examples of GaN materials include InGaIn, which may be used to form blue or green light emitters in some embodiments. Examples of GaIn materials include AlGaInP, which may be used to form red light emitters in some embodiments. In some embodiments, the light emitters **1044** may emit light of an initial color, which may be converted to other desired colors using phosphor materials or quantum dots. For example, the light emitter may emit blue light which excites a phosphor material or quantum dot that converts the blue wavelength light to green or red wavelengths.

With reference now to FIG. **12**, another example is illustrated of a wearable display system with a light projec-

tion system having multiple emissive micro-displays **1030a**, **1030b**, **1030c**. The illustrated display system is similar to the display system of FIG. **11A** except that the optical combiner **1050** has a standard X-cube prism configuration and includes light redirecting structures **1080a** and **1080c** for modifying the angle of incidence of light on the reflective surfaces **1052**, **1054** of the X-cube prism. It will be appreciated that a standard X-cube prism configuration will receive light which is normal to a face of the X-cube and redirect this light 45° such that it is output at a normal angle from a transverse face of the X-cube. However, this would cause the image light **1032a**, **1032b**, **1032c** to be incident on the same in-coupling optical element of the eyepiece **1020**. In order to provide different paths for the image light **1032a**, **1032b**, **1032c**, so that the image light is incident on associated ones of the in-coupling optical elements **1022a**, **1022b**, **1022c** of the waveguide assembly, the light redirecting structures **1080a**, **1080c** may be utilized.

In some embodiments, the light redirecting structures **1080a**, **1080c** may be lens structures. It will be appreciated that the lens structures may be configured to receive incident light and to redirect the incident light at an angle such that the light reflects off a corresponding one of the reflective surfaces **1052**, **1054** and propagates along a light path towards a corresponding one of the in-coupling optical elements **1022a**, **1022c**. As examples, the light redirecting structures **1080a**, **1080c** may comprise micro-lenses, nanolenses, reflective wells, metasurfaces, and liquid crystal gratings. In some embodiments, the micro-lenses, nanolenses, reflective wells, metasurfaces, and liquid crystal gratings may be organized in arrays. For example, each light emitter of the micro-displays **1030a**, **1030c** may be matched with one micro-lens. In some embodiments, in order to redirect light in a particular direction, the micro-lens or reflective wells may be asymmetrical and/or the light emitters may be disposed off-center relative to the micro-lens. In addition, in some embodiments, the light redirecting structures **1080a**, **1080c** may be collimators which narrow the angular emission profiles of associated light emitters, to increase the amount of light ultimately in-coupled into the eyepiece **1020**. Further details regarding such light redirecting structures **1080a**, **1080c** are discussed below regarding FIGS. **24A-27C**.

With reference now to FIG. **13A**, in some embodiments, two or more of the in-coupling optical elements **1022a**, **1022b**, **1022c** may overlap (e.g., as seen in a head-on view in the direction of light propagation into the in-coupling optical element **1022a**, **1022b**, **1022c**). FIG. **13A** illustrates an example of a side-view of a wearable display system with a light projection system **1010** having multiple emissive micro-displays **1032a**, **1032b**, **1032c** and an eyepiece **1020** with overlapping light in-coupling optical elements **1022a**, **1022c** and non-overlapping light in-coupling optical element **1022b**. As illustrated, the in-coupling optical elements **1022a**, **1022c** overlap, while the in-coupling optical elements **1022b** are laterally shifted. Stated another way, the in-coupling optical elements **1022a**, **1022c** are aligned directly in the paths of the image light **1032a**, **1032c**, while the image light **1032b** follows another path to the eyepiece **1020**, such that it is incident on an area of the eyepiece **1020** that is laterally shifted relative to the area in which the image light **1032a**, **1032c** is incident.

As illustrated, differences between the paths for the image light **1032b** and image light **1032a**, **1032c** may be established using light redirecting structures **1080a**, **1080c**. In some embodiments, the image light **1032b** from the emissive micro-display **1030b** proceeds directly through the

optical combiner **1052**. The image light **1032a** from the emissive micro-display **1032a** is redirected by the light redirecting structure **1080a** such that it reflects off of the reflective surface **1054** and propagates out of the optical combiner **1050** in the same direction as the image light **1032c**. It will be appreciated that the image light **1032c** from the emissive micro-display **1032c** is redirected by the light redirecting structure **1080c** such that it reflects off of the reflective surface **1052** at an angle such that the image light **1032c** propagates out of the optical combiner **1050** in the same direction as the image light **1032b**. Thus, the redirection of light by the light redirecting structures **1080a**, **1080c** and the angles of the reflective surfaces **1052**, **1054** are configured to provide a common path for the image light **1032a**, **1032c** out of the optical combiner **1050**, with this common path being different from the path of the image light **1032b**. In some other embodiments, one or both of the light redirecting structures **1080a**, **1080c** may be omitted and the reflective surfaces **1052**, **1054** in the optical combiner **1050** may be configured to reflect the image light **1032a**, **1032c** in the appropriate respective directions such that they exit the optical combiner **1050** propagating in the same direction, which is different from the direction of the image light **1032b**. As such, after propagating through the projection optics **1070**, the image light **1032a**, **1032c** exit from one exit pupil while the image light **1032b** exits from another exit pupil. In this configuration, the light projection system **1010** may be referred to as a two-pupil projection system.

In some embodiments, the light projection system **1010** may have a single output pupil and may be referred to as a single-pupil projection system. In such embodiments, the light projection system **1010** may be configured to direct the image light **1032a**, **1032b**, **1032c** onto a single common area of the eyepiece **1020**. Such a configuration is shown in FIG. **13B**, which illustrates a wearable display system with a light projection system **1010** having multiple emissive micro-displays **1030a**, **1030b**, **1030c** configured to direct light to a single light in-coupling area of the eyepiece **1020**. In some embodiments, as discussed further herein, the eyepiece **1020** may include a stack of waveguides having overlapping light in-coupling optical elements. In some other embodiments, a single light in-coupling optical element may be configured to in-couple light of all component colors into a single waveguide. The display system of FIG. **13B** is similar to the display system of FIG. **13A**, except for the omission of the light redirecting structures **1080a**, **1080c** and the use of the in-coupling optical element **1122a** and with the associated waveguide **1020a**. As illustrated, the in-coupling optical element **1122a** in-couples each of image light **1032a**, **1032b**, **1032c** into the waveguide **1020a**, which then relays the image light to the eye **210**. In some embodiments, the in-coupling optical element **1122a** may comprise a diffractive grating. In some embodiments, the in-coupling optical element **1122a** is a metasurface and/or liquid crystal grating.

As discussed herein, in some embodiments, the emissive micro-displays **1030a**, **1030b**, **1030c** may be monochrome micro-displays configured to emit light of different colors. In some embodiments, one or more of the emissive micro-displays **1030a**, **1030b**, **1030c** may have groups of light emitters configured to emit light of two or more, but not all, component colors. For example, a single emissive micro-display may have groups of light emitters—with at least one light emitter per group configured to emit blue light and at least one light emitter per group configured to emit green light—and a separate emissive micro-display on a different face of the X-cube **1050** may have light emitters configured

to emit red light. In some other embodiments, the emissive micro-displays **1030a**, **1030b**, **1030c** may each be full-color displays, each having light emitters of all component colors. As noted herein, utilizing multiple similar micro-displays may provide advantages for dynamic range and increased display brightness.

In some embodiments, a single full-color emissive micro-display may be utilized. FIG. 14 illustrates an example of a wearable display system with a single emissive micro-display **1030b**. The wearable display system of FIG. 14 is similar to the wearable display system of FIG. 14, except that the single emissive micro-display **1030b** is a full color micro-display configured to emit light of all component colors. As illustrated, the micro-display **1030b** emits image light **1032a**, **1032b**, **1032c** of each component color. In such embodiments, the optical combiner **1050** (FIG. 13B) may be omitted, which may advantageously reduce the weight and size of the wearable display system relative to a system with an optical combiner.

As discussed above, the in-coupling optical elements of the eyepiece **1020** may assume various configurations. Some examples of configurations for the eyepiece **1020** are discussed below in relation to FIGS. 15-23C.

FIG. 15 illustrates a side view of an example of an eyepiece **1020** having a stack of waveguides **1020a**, **1020b**, **1020c** with overlapping in-coupling optical elements **1022a**, **1022b**, **1022c**, respectively. It will be appreciated that the illustrated waveguide stack may be utilized in place of the single illustrated waveguide **1020a** of FIGS. 13B and 14. As discussed herein, each of the in-coupling optical elements **1022a**, **1022b**, **1022c** is configured to in-couple light having a specific color (e.g., light of a particular wavelength, or a range of wavelengths). In the illustrated orientation of the eyepiece **1020** in which the image light propagates vertically down the page towards the eyepiece **1020**, the in-coupling optical elements **1022a**, **1022b**, **1022c** are vertically aligned with each other (e.g., along an axis parallel to the direction of propagation of the image light **1032a**, **1032b**, **1032c**) such that they spatially overlap with each other as seen in a top down view (a head-on view in a direction of the image light **1032a**, **1032b**, **1032c** propagating to the in-coupling optical elements).

With continued reference to FIG. 15, as discussed herein, the projection system **1010** (FIGS. 13, 14) is configured to output a first monochrome color image, a second monochrome color image, and a third monochrome color image (e.g., red, green and blue color images) through the single-pupil of the projection system, the monochrome images being formed by the image light **1032a**, **1032b**, **1032c**, respectively. The in-coupling optical element **1022c** is configured to in-couple the image light **1032c** for the first color image into the waveguide **1020c** such that it propagates through the waveguide **1020c** by multiple total internal reflections at the upper and bottom major surfaces of the waveguide **1020c**, the in-coupling optical element **1022b** is configured to in-couple the image light **1032b** for the second color image into the waveguide **1020b** such that it propagates through the waveguide **1020b** by multiple total internal reflections at the upper and bottom major surfaces of the waveguide **1020b**, and the in-coupling optical element **1022a** is configured to in-couple the image light **1032a** for the third color image into the waveguide **1020a** such that it propagates through the waveguide **1020a** by multiple total internal reflections at the upper and bottom major surfaces of the waveguide **1020a**.

As discussed herein, the in-coupling optical element **1022c** is preferably configured to in-couple substantially all

the incident light **1032c** corresponding to the first color image into the associated waveguide **1020c** while allowing substantially all the incident light **1032b**, **1032a** corresponding to the second color image and the third color image, respectively, to be transmitted without being in-coupled. Similarly, the in-coupling optical element **1022b** is preferably configured to in-couple substantially all the incident image light **1032b** corresponding to the second color image into the associated waveguide **1020b** while allowing substantially all the incident light corresponding to the third color image to be transmitted without being in-coupled.

It will be appreciated that, in practice, the various in-coupling optical elements may not have perfect selectivity. For example, some of the image light **1032b**, **1032a** may undesirably be in-coupled into the waveguide **1020c** by the in-coupling optical element **1022c**; and some of the incident image light **1032a** may undesirably be in-coupled into the waveguide **1020b** by the in-coupling optical element **1022b**. Furthermore, some of the image light **1032c** may be transmitted through the in-coupling optical element **1022c** and in-coupled into waveguides **1020b** and/or **1020a** by the in-coupling optical elements **1020b** and/or **1020a**, respectively. Similarly, some of the image light **1032b** may be transmitted through the in-coupling optical element **1022b** and in-coupled into waveguide **1020a** by the in-coupling optical element **1022a**.

In-coupling image light for a color image into an unintended waveguide may cause undesirable optical effects, such as, for example cross-talk and/or ghosting. For example, in-coupling of the image light **1032c** for the first color image into unintended waveguides **1020b** and/or **1020a** may result in undesirable cross-talk between the first color image, the second color image and/or the third color image; and/or may result in undesirable ghosting. As another example, in-coupling of the image light **1032b**, **1032a** for the second or third color image, respectively, into the unintended waveguide **1020c** may result in undesirable cross-talk between the first color image, the second color image and/or the third color image; and/or may cause undesirable ghosting. In some embodiments, these undesirable optical effects may be mitigated by providing color filters (e.g., absorptive color filters) that may reduce the amount of incident light that is in-coupled into an unintended waveguide.

FIG. 16 illustrates a side view of an example of a stack of waveguides with color filters for mitigating ghosting or crosstalk between waveguides. The eyepiece **1020** of FIG. 16 is similar to that of FIG. 15, except for the presence of one or more of the color filters **1024c**, **1024b** and **1028**, **1026**. The color filters **1024c**, **1024b** are configured to reduce the amount of light unintentionally in-coupled into the waveguides **1020b** and **1020a**, respectively. The color filters **1028**, **1026** are configured to reduce the amount of unintentionally in-coupled image light which propagates through the waveguides **1020b**, **1020c**, respectively.

With continued reference to FIG. 16, a pair of color filters **1026** disposed on the upper and lower major surfaces of the waveguide **1020c** may be configured to absorb image light **1032a**, **1032b** that may have been unintentionally been in-coupled into waveguide **1020c**. In some embodiments, the color filter **1024c** disposed between the waveguides **1020c** and **1020b** is configured to absorb image light **1032c** that is transmitted through the in-coupling optical element **1022c** without being in-coupled. A pair of color filters **1028** disposed on the upper and lower major surfaces of the waveguide **1020b** is configured to absorb image light **1032a** that is in-coupled into waveguide **1020b**. A color filter **1024b**

disposed between the waveguides **1020b** and **1020a** is configured to absorb image light **1032b** that is transmitted through the in-coupling optical element **710**.

In some embodiments, the color filters **1026** on each major surface of the waveguide **1020c** are similar and are configured to absorb light of the wavelengths of both image light **1032a**, **1032b**. In some other embodiments, the color filter **1026** on one major surface of the waveguide **1020c** may be configured to absorb light of the color of image light **1032a**, and the color filter on the other major surface may be configured to absorb light of the color of image light **1032b**. In either arrangement, the color filters **1026** may be configured to selectively absorb the image light **1032a**, **1032b** propagating through the waveguide **1020c** by total internal reflection. For example, at TIR bounces of the image light **1032a**, **1032b** off the major surfaces of the waveguide **1020c**, the image light **1032a**, **1032b** contacts a color filter **1026** on those major surfaces and a portion of that image light is absorbed. Preferably, due to the selective absorption of image light **1032a**, **1032b** by the colors filters **1026**, the propagation of the in-coupled the image light **1032c** via TIR through the waveguide **1020c** is not appreciably affected.

Similarly, the plurality of color filters **1028** may be configured as absorption filters that absorb in-coupled image light **1032a** that propagates through the waveguide **1020b** by total internal reflection. At TIR bounces of the image light **1032a** off the major surfaces of the waveguide **1020b**, the image light **1032a** contacts a color filter **1028** on those major surfaces and a portion of that image light is absorbed. Preferably, the absorption of the image light **1032a** is selective and does not affect the propagation of the in-coupled image light **1032b** that is also propagating via TIR through the waveguide **1020b**.

With continued reference to FIG. 16, the color filters **1024c** and **1024b** may also be configured as absorption filters. The color filter **1024c** may be substantially transparent to light of the colors of the image light **1032a**, **1032b** such that the image light **1032a**, **1032b** is transmitted through the color filter **1024c** with little to no attenuation, while light of the color of the image light **1032c** is selectively absorbed. Similarly, the color filter **1024b** may be substantially transparent to light of the color of the image light **1032a** such that incident image light **1032a** is transmitted through the color filter **1024b** with little to no attenuation, while light of the color of the image light **1032b** is selectively absorbed. The color filter **1024c** may be disposed on a major surface (e.g., the upper major surface) of the waveguide **1020b** as shown in FIG. 16. Alternately, the color filter **1024c** may be disposed on a separate substrate positioned between the waveguides **1020c** and **1020b**. Likewise, the color filter **1024b** may be disposed on a major surface (e.g., an upper major surface) of the waveguide **1020a**. Alternately, the color filter **1024b** may be disposed on a separate substrate positioned between the waveguides **1020b** and **1020a**. It will be appreciated that the color filters **1024c** and **1024b** may be vertically aligned with the single-pupil of the projector that outputs the image light **1032a**, **1032b**, **1032c** (in orientations where the image light **1032a**, **1032b**, **1032c** propagates vertically to the waveguide stack **1020**, as illustrated).

In some embodiments, the color filters **1026** and **1028** may have single-pass attenuation factors of less than about 10%, (e.g., less than or equal to about 5%, less than or equal to about 2%, and greater than about 1%) to avoid significant undesired absorption of light propagating through the thickness the waveguides **1020c**, **1020b** (e.g., light of the colors of the image light **1032a**, **1032b** propagating through the

waveguides **1020c**, **1020b** from the ambient environment and/or other waveguides). Various embodiments of the color filters **1024c** and **1024b** may be configured to have low attenuation factors for the wavelengths that are to be transmitted and high attenuation factor for the wavelengths that are to be absorbed. For example, in some embodiments, the color filter **1024c** may be configured to transmit greater than 80%, greater than 90%, or greater than 95%, of incident light having the colors of the image light **1032a**, **1032b** and absorb greater than 80%, greater than 90%, or greater than 95%, of incident light having the color of the image light **1032a**. Similarly, the color filter **1024b** may be configured to transmit greater than 80%, greater than 90%, or greater than 95%, of incident light having the color of the image light **1032a** and absorb greater than 80%, greater than 90%, or greater than 95%, of incident light having the color of the image light **1032b**.

In some embodiments, the color filters **1026**, **1028**, **1024c**, **1024b** may comprise a layer of color selective absorbing material deposited on one or both surfaces of the waveguide **1020c**, **1020b** and/or **1020a**. The color selective absorbing material may comprise a dye, an ink, or other light absorbing material such as metals, semiconductors, and dielectrics. In some embodiments, the absorption of material such as metals, semiconductors, and dielectrics may be made color selective by utilizing these materials to form subwavelength gratings (e.g., a grating that does not diffract the light). The gratings may be made of plasmonics (e.g. gold, silver, and aluminum) or semiconductors (e.g. silicon, amorphous silicon, and germanium).

The color selective material may be deposited on the substrate using various deposition methods. For example, the color selective absorbing material may be deposited on the substrate using jet deposition technology (e.g., ink-jet deposition). Ink-jet deposition may facilitate depositing thin layers of the color selective absorbing material. Because ink-jet deposition allows for the deposition to be localized on selected areas of the substrate, ink-jet deposition provides a high degree of control over the thicknesses and compositions of the layers of the color selective absorbing material, including providing for nonuniform thicknesses and/or compositions across the substrate. In some embodiments, the color selective absorbing material deposited using ink-jet deposition may have a thickness between about 10 nm and about 1 micron (e.g., between about 10 nm and about 50 nm, between about 25 nm and about 75 nm, between about 40 nm and about 100 nm, between about 80 nm and about 300 nm, between about 200 nm and about 500 nm, between about 400 nm and about 800 nm, between about 500 nm and about 1 micron, or any value in a range/sub-range defined by any of these values). Controlling the thickness of the deposited layer of the color selective absorbing material may be advantageous in achieving a color filter having a desired attenuation factor. Furthermore, layers having different thickness may be deposited in different portions of the substrate. Additionally, different compositions of the color selective absorbing material may be deposited in different portions of the substrate using ink-jet deposition. Such variations in composition and/or thickness may advantageously allowing for location-specific variations in absorption. For example, in areas of a waveguide in which transmission of light from the ambient (to allow the viewer to see the ambient environment) is not necessary, the composition and/or thickness may be selected to provide high absorption or attenuation of selected wavelengths of light. Other depo-

sition methods such as coating, spin-coating, spraying, etc. may be employed to deposit the color selective absorbing material on the substrate.

FIG. 17 illustrates an example of a top-down view of the waveguide assemblies of FIGS. 15 and 16. As illustrated, in-coupling optical elements 1022a, 1022b, 1022c spatially overlap. In addition, the waveguides 1020a, 1020b, 1020c, along with each waveguide's associated light distributing element 730, 740, 750 and associated out-coupling optical element 800, 810, 820, may be vertically aligned. The in-coupling optical elements 1022a, 1022b, 1022c are configured to in-couple incident image light 1032a, 1032b, 1032c (FIGS. 15 and 16), respectively, in waveguides 1020a, 1020b, 1020c, respectively, such that the image light propagates towards the associated light distributing element 730, 740, 750 by TIR.

FIG. 18 illustrates another example of a top-down view of the waveguide assemblies of FIGS. 15 and 16. As in FIG. 17, in-coupling optical elements 1022a, 1022b, 1022c spatially overlap and the waveguides 1020a, 1020b, 1020c are vertically aligned. In place of each waveguide's associated light distributing element 730, 740, 750 and associated out-coupling optical element 800, 810, 820, however, are combined OPE/EPE's 1281, 1282, 1283, respectively. The in-coupling optical elements 1022a, 1022b, 1022c are configured to in-couple incident image light 1032a, 1032b, 1032c (FIGS. 15 and 16), respectively, in waveguides 1020a, 1020b, 1020c, respectively, such that the image light propagates towards the associated combined OPE/EPE's 1281, 1282, 1283 by TIR.

While FIGS. 15-18 show overlapping in-coupling optical elements for a single-pupil configuration of the display system, it will be appreciated that the display system may have a two-pupil configuration in some embodiments. In such a configuration, where three component colors are utilized, image light for two colors may have overlapping in-coupling optical elements, while image light for a third color may have a laterally-shifted in-coupling optical element. For example, the optical combiner 1050 (FIGS. 11A, 12, 13A-13B) and/or light redirecting structures 1080a, 1080b, 1080c may be configured to direct image light through the projection optics 1070 such that image light of two colors are incident on directly overlapping areas of the eyepiece 1020 while another color of the image light is incident on an area that is laterally-shifted. For example, the reflective surfaces 1052, 1054 (FIG. 11A) may be angled such that image light of one color follows a common light path with image light from the emissive micro-display 1030b, while image light of another color follows a different light path. In some embodiments, rather than having both light redirecting structures 1080a, 1080c (FIG. 12), one of these light redirecting structures may be omitted, so that only light from one of the micro-displays 1030a, 1030c is angled to provide a different light path from the light emitted by the other two micro-displays.

FIG. 19A illustrates a side view of an example of an eyepiece having a stack of waveguides with some overlapping and some laterally-shifted in-coupling optical elements. The eyepiece of FIG. 19A is similar to the eyepiece of FIG. 15, except that one of the in-coupling optical elements is laterally shifted relative to the other in-coupling optical elements. In the illustrated orientation of the eyepiece 1020 in which the image light propagates vertically down the page towards the eyepiece 1020, the in-coupling optical elements 1022a, 1022c are vertically aligned with each other (e.g., along an axis parallel to the direction of propagation of the image light 1032a, 1032c) such that they spatially overlap

with each other as seen in a head-on view in a direction of the image light 1032a, 1032c propagating to the in-coupling optical elements 1022a, 1022b, 1022c. As seen in the same head-on view (e.g., as seen in a top-down view in the illustrated orientation), the in-coupling optical element 1022b is shifted laterally relative to the other in-coupling optical elements 1022a, 1022c. Light for the in-coupling optical element 1022b is output to the eyepiece 1020 through a different exit pupil than light for the in-coupling optical elements 1022a, 1022c. It will be appreciated that the illustrated waveguide stack comprising the waveguides 1020a, 1020b, 1020c may be utilized in place of the single illustrated waveguide 1020a of FIGS. 13 and 14.

With continued reference to FIG. 19, the in-coupling optical element 1022c is configured to in-couple the image light 1032c into the waveguide 1020c such that it propagates through the waveguide 1020c by multiple total internal reflections between the upper and bottom major surfaces of the waveguide 1020c, the in-coupling optical element 1022b is configured to in-couple the image light 1032b into the waveguide 1020b such that it propagates through the waveguide 1020b by multiple total internal reflections between the upper and bottom major surfaces of the waveguide 1020b, and the in-coupling optical element 1022a is configured to in-couple the image light 1032a into the waveguide 1020a such that it propagates through the waveguide 1020a by multiple total internal reflections between the upper and bottom major surfaces of the waveguide 1020a.

The in-coupling optical element 1022c is preferably configured to in-couple all the incident light 1032c into the associated waveguide 1020c while being transmissive to all the incident light 1032a. On the other hand, the image light 1032b may propagate to the in-coupling optical element 1022b without needing to propagate through any other in-coupling optical elements. This may be advantageous in some embodiments by allowing light, to which the eye is more sensitive, to be incident on a desired in-coupling optical element without any loss or distortion associated with propagation through other in-coupling optical elements. Without being limited by theory, in some embodiments, the image light 1032b is green light, to which the human eye is more sensitive. It will be appreciated that, while the waveguides 1020a, 1020b, 1020c are illustrated arranged a particular order, in some embodiments, the order of the waveguides 1020a, 1020b, 1020c may differ.

It will be appreciated that, as discussed herein, the in-coupling optical element 1022c overlying the in-coupling optical elements 1022a may not have perfect selectivity. Some of the image light 1032a may undesirably be in-coupled into the waveguide 1020c by the in-coupling optical element 1022c; and some of the image light 1032c may be transmitted through the in-coupling optical element 1022c, after which the image light 1032c may strike the in-coupling optical element 1020a and be in-coupled into the waveguide 1020a. As discussed herein, such undesired in-coupling may be visible as ghosting or crosstalk.

FIG. 19B illustrates a side view of an example of the eyepiece of FIG. 19A with color filters for mitigating ghosting or crosstalk between waveguides. In particular, color filters 1024c and/or 1026 are added to the structures shown in FIG. 19A. As illustrated, the in-coupling optical element 1022c may unintentionally in-couple a portion of the image light 1032a into the waveguide 1020c. In addition, or alternatively, a portion of the image light 1032c undesirably be transmitted through the in-coupling optical element 1022c after which it may unintentionally be in-coupled by the in-coupling optical element 1022a.

To mitigate unintentionally in-couple image light **1032a** propagating through the waveguide **1022c**, absorptive color filters **1026** may be provided on one or both major surfaces of the waveguide **1022c**. The absorptive color filters **1026** may be configured to absorb light of the color of the unintentionally in-coupled image light **1032a**. As illustrated, the absorptive color filters **1026** are disposed in the general direction of propagation of the image light through the waveguide **1020c**. Thus, the absorptive color filters **1026** are configured to absorb image light **1032a** as that light propagates through the waveguide **1020c** by TIR and contacts the absorptive color filters **1026** while reflecting off one or both of the major surfaces of the waveguide **1020c**.

With continued reference to FIG. **19B**, to mitigate image light **1032c** which propagates through the in-coupling optical element **1022c** without being in-coupled, the absorptive color filter **1024c** may be provided forward of the in-coupling optical element **1022a**. The absorptive color filter **1024c** is configured to absorb light of the color of the image light **1032c**, to prevent that light from propagating to the in-coupling optical element **1022a**. While illustrated between the waveguides **1020c** and **1020b**, in some other embodiments, the absorptive color filter **1024c** may be disposed between the waveguides **1020b** and **1020a**. It will be appreciated that further details regarding the composition, formation, and properties of the absorptive color filters **1024c** and **1026** are provided in the discussion of FIG. **16**.

It will also be appreciated that in the embodiments illustrated in FIGS. **16** and **19B**, one or more of the color filters **1026**, **1028**, **1024c**, and **1024b** may be omitted if one or more in-coupling optical elements **1022a**, **1022b**, **1022c** have sufficiently high selectivity for the color of the light that is intended to be in-coupled into the associated waveguide **1020a**, **1020b**, **1022c**, respectively.

FIG. **20A** illustrates an example of a top-down view of the eyepieces of FIGS. **19A** and **19B**. As illustrated, in-coupling optical elements **1022a**, **1022c** spatially overlap, while in-coupling optical element **1022b** is laterally-shifted. In addition, the waveguides **1020a**, **1020b**, **1020c**, along with each waveguide's associated light distributing element **730**, **740**, **750** and associated out-coupling optical element **800**, **810**, **820**, may be vertically aligned. The in-coupling optical elements **1022a**, **1022b**, **1022c** are configured to in-couple incident image light **1032a**, **1032b**, **1032c** (FIGS. **15** and **16**), respectively, in waveguides **1020a**, **1020b**, **1020c**, respectively, such that the image light propagates towards the associated light distributing element **730**, **740**, **750** by TIR.

FIG. **20B** illustrates another example of a top-down view of the waveguide assembly of FIGS. **19A** and **19B**. As in FIG. **20A**, in-coupling optical elements **1022a**, **1022c** spatially overlap, the in-coupling optical element is laterally-shifted, and the waveguides **1020a**, **1020b**, **1020c** are vertically aligned. In place of each waveguide's associated light distributing element **730**, **740**, **750** and associated out-coupling optical element **800**, **810**, **820**, however, are combined OPE/EPE's **1281**, **1282**, **1283**, respectively. The in-coupling optical elements **1022a**, **1022b**, **1022c** are configured to in-couple incident image light **1032a**, **1032b**, **1032c** (FIGS. **15** and **16**), respectively, in waveguides **1020a**, **1020b**, **1020c**, respectively, such that the image light propagates towards the associated combined OPE/EPE's **1281**, **1282**, **1283** by TIR.

With reference now to FIG. **21**, it will be appreciated that re-bounce of in-coupled light may undesirably occur in waveguides. Re-bounce occurs when in-coupled light propagating along a waveguide strikes the in-coupling optical

element a second or subsequent time after the initial in-coupling incidence. Re-bounce may result in a portion of the in-coupled light being undesirably out-coupled and/or absorbed by a material of the in-coupling optical element. The out-coupling and/or light absorption undesirably may cause a reduction in overall in-coupling efficiency and/or uniformity of the in-coupled light.

FIG. **21** illustrates a side view of an example of re-bounce in a waveguide **1030a**. As illustrated, image light **1032a** is in-coupled into the waveguide **1030a** by in-coupling optical element **1022a**. In-coupling optical element **1022a** redirects the image light **1032a** such that it generally propagates through the waveguide in the direction **1033**. Re-bounce may occur when in-coupled image light internally reflects or bounces off a major surface of the waveguide **1030a** opposite the in-coupling optical element **1022a** and is incident on or experiences a second bounce (a re-bounce) at the in-coupling optical element **1022a**. The distance between two neighboring bounces on the same surface of the waveguide **1030a** is indicated by spacing **1034**.

Without being limited by theory, it will be appreciated that the in-coupling optical element **1022a** may behave symmetrically; that is, it may redirect incident light such that the incident light propagates through the waveguide at TIR angles. However, light that is incident on the diffractive optical elements at TIR angles (such as upon re-bounce) may also be out-coupled. In addition or alternatively, in embodiments where the in-coupling optical element **1022a** is coated with a reflective material, it will be understood that the reflection of light off of a layer of material such as metal may also involve partial absorption of the incident light, since reflection may involve the absorption and emission of light from a material. As a result, light out-coupling and/or absorption may undesirably cause loss of in-coupled light. Accordingly, re-bounced light may incur significant losses, as compared with light that interacts only once with the in-coupling optical element **1022a**.

In some embodiments, the in-coupling elements are configured to mitigate in-coupled image light loss due to re-bounce. Generally, re-bounce of in-coupled light occurs towards the end **1023** of the in-coupling optical element **1022a** in the propagation direction **1033** of the in-coupled light. For example, light in-coupled at the end of the in-coupling optical element **1022a** opposite the end **1023** may re-bounce if the spacing **1034** for that light is sufficiently short. To avoid such re-bounce, in some embodiments, the in-coupling optical element **1022a** is truncated at the propagation direction end **1023**, to reduce the width **1022w** of the in-coupling optical element **1022a** along which re-bounce is likely to occur. In some embodiments, the truncation may be a complete truncation of all structures of the in-coupling optical element **1022a** (e.g., the metallization and diffractive gratings). In some other embodiments, for example, where the in-coupling optical element **1022a** comprises a metalized diffraction grating, a portion of the in-coupling optical element **1022a** at the propagation direction end **1023** may not be metalized, such that the propagation direction end **1023** of the in-coupling optical element **1022a** absorbs less re-bouncing light and/or outcouples re-bouncing light with a lower efficiency. In some embodiments, a diffractive region of an in-coupling optical element **1022a** may have a width along a propagation direction **1033** shorter than its length perpendicular to the propagation direction **1033**, and/or may be sized and shaped such that a first portion of image light **1032a** is incident on the in-coupling optical element **1022a** and a second portion of the beam of light impinges on the waveguide **1030a** without

being incident on the in-coupling optical element **1022a**. While waveguide **1032a** and light in-coupling optical element **1022a** are illustrated alone for clarity, it will be appreciated that re-bounce and the strategies discussed for reducing re-bounce may apply to any of the in-coupling optical elements disclosed herein. It will also be appreciated that the spacing **1034** is related to the thickness of the waveguide **1030a** (a larger thickness results in a larger spacing **1034**). In some embodiments, the thickness of individual waveguides may be selected to set the spacing **1034** such that re-bounce does not occur. Further details regarding re-bounce mitigation may be found in U.S. Provisional Application No. 62/702,707, filed on Jul. 24, 2018, the entire disclosure of which is incorporated by reference herein.

FIGS. **22A-23C** illustrate examples of top-down views of an eyepiece having in-coupling optical elements configured to reduce re-bounce. In-coupling optical element **1022a**, **1022b**, **1022c** are configured to in-couple light such that it propagates in a propagation direction towards the associated light distributing elements **730**, **740**, **750** (FIGS. **22A-22C**) or combined OPE/EPE's **1281**, **1282**, **1283** (FIGS. **23A-23C**). As illustrated, the in-coupling optical element **1022a**, **1022b**, **1022c** may have a shorter dimension along the propagation direction and a longer dimension along the transverse axis. For example, the in-coupling optical element **1022a**, **1022b**, **1022c** may each be in the shape of a rectangle with a shorter side along the axis of the propagation direction and a longer side along an orthogonal axis. It will be appreciated that the in-coupling optical elements **1022a**, **1022b**, **1022c** may have other shapes (e.g., orthogonal, hexagonal, etc.). In addition, different ones of the in-coupling optical elements **1022a**, **1022b**, **1022c** may have different shapes in some embodiments. Also, preferably, as illustrated, non-overlapping in-coupling optical elements may be positioned such that they are not in the propagation direction of other in-coupling optical elements. For example, as shown in FIGS. **22A**, **22B**, **23A**, and **23B**, the non-overlapping in-coupling optical elements may be arranged in a line along an axis crossing (e.g., orthogonal to) the axis of the propagation direction.

It will be appreciated that in the waveguide assemblies of FIGS. **22A-22C** are similar, except for the overlap of the in-coupling optical elements **1022a**, **1022b**, **1022c**. For example, FIG. **22A** illustrates in-coupling optical elements **1022a**, **1022b**, **1022c** with no overlap. FIG. **22B** illustrates overlapping in-coupling optical elements **1022a**, **1022c**, and non-overlapping in-coupling optical elements **1022b**. FIG. **22C** illustrates overlap between all the in-coupling optical elements **1022a**, **1022b**, **1022c**.

The waveguide assemblies of FIGS. **23A-23C** are also similar, except for the overlap of the in-coupling optical elements **1022a**, **1022b**, **1022c**. FIG. **23A** illustrates in-coupling optical elements **1022a**, **1022b**, **1022c** with no overlap. FIG. **23B** illustrates overlapping in-coupling optical elements **1022a**, **1022c**, and non-overlapping in-coupling optical elements **1022b**. FIG. **22C** illustrates overlap between all the in-coupling optical elements **1022a**, **1022b**, **1022c**.

With reference now to FIG. **24A**, it will be appreciated that the emissive micro-displays have high etendue, which presents a challenge for efficient light utilization. As discussed herein, the emissive micro-displays may include a plurality of individual light emitters. Each of these light emitters may have a large angular emission profile, e.g., a Lambertian or near-Lambertian emission profile. Undesir-

ably, not all of this light may be captured and directed to the eyepiece of the display system.

FIG. **24A** illustrates an example of angular emission profiles of light emitted by individual light emitters **1044** of an emissive micro-display **1032**, and light captured by projection optics **1070**. The illustrated emissive micro-display **1032** may correspond to any of the emissive-micro-displays disclosed herein, including the emissive micro-displays **1032a**, **1032b**, **1032c**. As illustrated, the projection optics **1070** may be sized such that it will capture light having an angular emission profile **1046**. However, the angular emission profiles **1046** in the light emitters **1044** is significantly larger; not all of the light emitted by the light emitters **1044** will be incident on the projection optics **1070**, nor necessarily incident at angles at which the light will propagate into and through the projection optics **1070**. As a result, some of the light emitted by the light emitter **1044** may undesirably be "wasted" since it is not captured and ultimately relayed to the user's eye to form images. This may result in images that appear darker than would be expected if more of the light outputted by the light emitters **1040** ultimately reached the user's eye.

In some embodiments, one strategy for capturing more of the light emitted by the light emitters **1040** is to increase the size of the projection optics **1070**, to increase the size of the numerical aperture of the projection optics **1070** capturing light. In addition or alternatively, the projection optics **1070** may also be formed with high refractive index materials (e.g., having refractive indices above 1.5) which may also facilitate light collection. In some embodiments, the projection optics **1070** may utilize a lens sized to capture a desired, high proportion of the light emitted by the light emitters **1044**. In some embodiments, the projection optics **1070** may be configured to have an elongated exit pupil, e.g., to emit light beams having a cross-sectional profile similar to the shapes of the in-coupling optical elements **1022a**, **1022b**, **1022c** of FIGS. **22A-23C**. For example, the projection optics **1070** may be elongated in a dimension corresponding to the elongated dimension of the in-coupling optical elements **1022a**, **1022b**, **1022c** of FIGS. **22A-23C**. Without being limited by theory, such elongated in-coupling optical elements **1022a**, **1022b**, **1022c** may improve the etendue mismatch between the emissive micro-display and the eyepiece **1020** (FIGS. **22A-23C**). In some embodiments, the thickness of the waveguides of the eyepiece **1020** (e.g., FIGS. **11A**, and **12-23C**) may be selected to increase the percentage of light effectively captured, e.g., by reducing re-bounce by increasing the re-bounce spacing, as discussed herein.

In some embodiments, one or more light collimators may be utilized to reduce or narrow the angular emission profile of light from the light emitters **1044**. As a result, more of the light emitted by the light emitters **1044** may be captured by the projection optics **1070** and relayed to the eyes of a user, advantageously increasing the brightness of images and the efficiency of the display system. In some embodiments, the light collimators may allow the light collection efficiency of the projection optics (the percentage of light emitted by the light emitters **1044** that is captured by the projection optics) to reach values of 80% or more, 85% or more, or 90% or more, including about 85-95% or 85-90%. In addition, the angular emission profile of the light from the light emitters **1044** may be reduced to 60° or less, 50° or less, or 40° or less (from, e.g., 180°). In some embodiments, the reduced angular emission profiles may be in the range of about 30-60°, 30-50°, or 30-40°. It will be appreciated that light from the light emitters **1044** may make out the shape of a cone, with the light emitter **1044** at the vertex of the cone. The angular

mission profile refers to the angle made out by the sides of the cone, with the associated light emitter **1044** at the vertex of the angle (as seen in a cross-section taken along a plane extending through the middle of the cone and including the cone apex).

FIG. **24B** illustrates an example of the narrowing of angular emission profiles using an array of light collimators. As illustrated, the emissive micro-display **1032** includes an array of light emitters **1044**, which emit light with an angular emission profile **1046**. An array **1300** of light collimators **1302** is disposed forward of the light emitters **1044**. In some embodiments, each light emitter **1044** is matched 1-to-1 with an associated light collimator **1302** (one light collimator **1302** per light emitter **1044**). Each light collimator **1302** redirects incident light from the associated light emitter **1044** to provide a narrowed angular emission profiles **1047**. Thus, the relatively large angular emission profiles **1046** are narrowed to the smaller angular emission profiles **1047**.

In some embodiments, the light collimators **1302** and array **1300** may be part of the light redirecting structures **1080a**, **180c** of FIGS. **12** and **13A**. Thus, light collimators **1302** may narrow the angular emission profile of the light emitters **1044** and also redirect the light such that it propagates into the optical combiner **1050** at the appropriate angles to define multiple light paths and the related multiple exit pupils. It will be appreciated that light may be redirected in particular directions by appropriately shaping the light collimators **1302**.

Preferably, the light collimators **1302** are positioned in tight proximity to the light emitters **1044** to capture a large proportion of the light outputted by the light emitters **1044**. In some embodiments, there may be a gap between the light collimators **1302** and the light emitters **1044**. In some other embodiments, the light collimator **1302** may be in contact with the light emitters **1044**. It will be appreciated that the angular emission profile **1046** may make out a wide cone of light. Preferably, the entirety or majority of a cone of light from a light emitter **1044** is incident on a single associated light collimator **1302**. Thus, in some embodiments, each light emitter **1044** is smaller (occupies a smaller area) than the light receiving face of an associated light collimator **1302**. In some embodiments, each light emitter **1044** has a smaller width than the spacing between neighboring far light emitters **1044**.

Advantageously, the light collimators **1302** may increase the efficiency of the utilization of light and may also reduce the occurrence of crosstalk between neighboring light emitters **1044**. It will be appreciated that crosstalk between light emitters **1044** may occur when light from a neighboring light emitter is captured by a light collimator **1302** not associated with that neighboring light emitter. That captured light may be propagated to the user's eye, thereby providing erroneous image information for a given pixel.

With reference to FIGS. **24A** and **24B**, the size of the beam of light captured by the projection optics **1070** may influence the size of the beam of light which exits the projection optics **1070**. As shown in FIG. **24A**, without the use light collimators, the exit beam may have a relatively large width **1050**. As shown in FIG. **24B**, with light collimators **1302**, the exit beam may have a smaller width **1052**. Thus, in some embodiments, the light collimators **1302** may be used to provide a desired beam size for in-coupling into an eyepiece. For example, the amount that the light collimators **1302** narrow the angular emission profile **1046** may be selected based at least partly upon the size of the intra-coupling optical elements in the eyepiece to which the light outputted by the projection optics **1070** is directed.

It will be appreciated that the light collimators **1302** may take various forms. For example, the light collimators **1302** may be micro-lenses or lenslets, in some embodiments. As discussed herein, each micro-lens preferably has a width greater than the width of an associated light emitter **1044**. The micro-lenses may be formed of curved transparent material, such as glass or polymers, including photoresist and resins such as epoxy. In some embodiments, light collimators **1302** may be nano-lenses, e.g., diffractive optical gratings. In some embodiments, light collimators **1302** may be metasurfaces and/or liquid crystal gratings. In some embodiments, light collimator's **1302** may take the form of reflective wells.

It will be appreciated that different light collimators **1302** may have different dimensions and/or shapes depending upon the wavelengths or colors of light emitted by the associated light emitter **1044**. Thus, for full-color emissive micro-displays, the array **1300** may include a plurality of light collimators **1302** with different dimensions and/or shapes depending upon the color of light emitted by the associate light emitter **1044**. In embodiments where the emissive micro-display is a monochrome micro-display, the array **1300** may be simplified, with each of the light collimators **1302** in the array being configured to redirect light of the same color. With such monochrome micro-displays, the light collimator **1302** may be similar across the array **1300** in some embodiments.

With continued reference to FIG. **24B**, as discussed herein, the light collimators **1302** may have a 1-to-1 association with the light emitters **1044**. For example, each light emitter **1044** may have a discrete associated light collimator **1302**. In some other embodiments, light collimators **1302** may be elongated such that they extend across multiple light emitters **1044**. For example, in some embodiments, the light collimator **1302** may be elongated into the page and extend in front of a row of multiple light emitters **1044**. In some other embodiments, a single light collimator **1302** may extend across a column of light emitters **1044**. In yet other embodiments, the light collimator **1302** may comprise stacked columns and/or rows of lens structures (e.g., nano-lens structures, micro-lens structures, etc.).

As noted above, the light collimators **1302** may take the form of reflective wells. FIG. **25A** illustrates an example of a side view of an array of tapered reflective wells for directing light to projection optics. As illustrated, the light collimator array **1300** may include a substrate **1301** in which a plurality of light collimators **1302**, in the form of reflective wells, may be formed. Each well may include at least one light emitter **1044**, which may emit light with a Lambertian angular emission profile **1046**. The reflective walls **1303** of the wells of the light collimators **1302** are tapered and reflect the emitted light such that it is outputted from the well with a narrower angular emission profile **1047**. As illustrated, reflective walls **1303** may be tapered such that the cross-sectional size increases with distance from the light emitter **1044**. In some embodiments, the reflective walls **1303** may be curved. For example, the sides **1303** may have the shape of a compound parabolic concentrator (CPC).

With reference now to FIG. **25B**, an example of a side view of an asymmetric tapered reflective well is illustrated. As discussed herein, e.g., as illustrated in FIGS. **12A-13A**, it may be desirable to utilize the light collimators **1302** to steer light in a particular direction not normal to the surface of the light emitter **1044**. In some embodiments, as viewed in a side view such as illustrated in FIG. **25B**, the light collimator **1302** may be asymmetric, with the upper side **1303a** forming a different angle (e.g., a larger angle) with the

surface of the light emitter **1044** than the lower side **1303b**; for example, the angles of the reflective walls **1303a**, **1303b** relative to the light emitter **1044** may differ on different sides of the light collimators **1302** in order to direct the light in the particular non-normal direction. Thus, as illustrated, light exiting the light collimator **1302** may propagate generally in a direction **1048** which is not normal to the surface of the light emitter **1044**. In some other embodiments, in order to direct light in the direction **1048**, the taper of the upper side **1303a** may be different than the taper of the lower side; for example, the upper side **1303a** may flare out to a greater extent than the lower side **1303b**.

With continued reference to FIG. 25, the substrate **1301** may be formed of various materials having sufficient mechanical integrity to maintain the desired shape of the reflective walls **1303**. Examples of suitable materials include metals, plastics, and glasses. In some embodiments, the substrate **1301** may be a plate of material. In some embodiments, substrate **1301** is a continuous, unitary piece of material. In some other embodiments, the substrate **1301** may be formed by joining together two or more pieces of material.

The reflective walls **1303** may be formed in the substrate **1301** by various methods. For example, the walls **1303** may be formed in a desired shape by machining the substrate **1301**, or otherwise removing material to define the walls **1303**. In some other embodiments, the walls **1303** may be formed as the substrate **1301** is formed. For example, the walls **1303** may be molded into the substrate **1301** as the substrate **1301** is molded into its desired shape. In some other embodiments, the walls **1303** may be defined by rearrangement of material after formation of the body **2200**. For example, the walls **1303** may be defined by imprinting.

Once the contours of the walls **1303** are formed, they may undergo further processing to form surfaces having the desired degree of reflection. In some embodiments, the surface of the substrate **1301** may itself be reflective, e.g., where the body is formed of a reflective metal. In such cases, the further processing may include smoothing or polishing the interior surfaces of the walls **1303** to increase their reflectivity. In some other embodiments, the interior surfaces of the reflectors **2110** may be lined with a reflective coating, e.g., by a vapor deposition process. For example, the reflective layer may be formed by physical vapor deposition (PVD) or chemical vapor deposition (CVD).

It will be appreciated that the location of a light emitter relative to an associated light collimator may influence the direction of emitted light out of the light collimator. This is illustrated, for example, in FIGS. 26A-26C, which illustrate examples of differences in light paths for light emitters at different positions relative to center lines of overlying, associated light collimators. As shown in FIG. 26A, the emissive micro-display another 30 has a plurality of light emitters **1044a**, each having an associated light collimator **1302** which facilitates the output of light having narrowed angular emission profiles **1047**. The light passes through the projection optics **1070** (represented as a simple lens for ease of illustration), which converges the light from the various light emitters **1044a** onto an area **1402a**.

With continued reference to FIG. 26A, in some embodiments, each of the light collimators **1302** may be symmetric and may have a center line which extends along the axis of symmetry of the light collimator. In the illustrated configuration, the light emitters **1044a** are disposed on the center line of each of the light collimators **1302**.

With reference now to FIG. 26B, light emitters **1044b** are offset by a distance **1400** from the center lines of their

respective light collimators **1302**. This offset causes light from the light emitters **1044b** to take a different path through the light collimators **1302**, which output light from the light emitters **1044b** with narrowed angular emission profiles **1047b**. The projection optics **1070** then converges the light from the light emitters **1044b** onto the area **1402b**, which is offset relative to the area **1402a** on which light from the light emitters **1044a** converge.

With reference now to FIG. 26C, light emitters **1044c** offset from both the light emitters **1044a** and **1044b** are illustrated. This offset causes light from the light emitters **1044c** to take a different path through the light collimators **1302** than light from the light emitters **1044a** and **1044b**. This causes the light collimators **1302** to output light from the light emitters **1044c** with narrowed angular emission profiles that take a different path to the projection optics **1070** than the light from the light emitters **1044a** and **1044b**. Ultimately, the projection optics **1070** converges the light from the light emitters **1044c** onto the area **1402c**, which is offset relative to the areas **1402a** and **1402b**.

With reference to FIGS. 26A-26C, each triad of light emitters **1044a**, **1044b**, **1044c** may share a common light collimator **1302**. In some embodiments, the micro-display **1030** may be a full-color micro-display and each light emitter **1044a**, **1044b**, **1044c** may be configured to emit light of a different component color. Advantageously, the offset areas **1402a**, **1402b**, **1402c** may correspond to the in-coupling optical elements of a waveguide in some embodiments. For example, the areas **1402a**, **1402b**, **1402c** may correspond to the in-coupling optical element **1022a**, **1022b**, **1022c**, respectively, of FIGS. 11A and 12. Thus, the light collimators **1302** and the offset orientations of the light emitters **1044a**, **1044b**, **1044c** may provide an advantageously simple three-pupil projection system **1010** using a full-color emissive micro-display.

As noted herein, the light collimator **1302** may also take the form of a nano-lens. FIG. 27 illustrates an example of a side view of individual light emitters **1044** of an emissive micro-display **1030** with an overlying array **1300** of light collimators **1302** which are nano-lenses. As discussed herein, individual ones of the light emitters **1044** may each have an associated light collimator **1302**. The light collimators **1302** redirect light from the light emitters **1044** to narrow the large angular emission profile **1046** of the light emitters **1044**, to output light with the narrowed angular emission profile **1047**.

With continued reference to FIG. 27, in some embodiments, the light collimators **1302** may be grating structures. In some embodiments, the light collimators **1302** may be gratings formed by alternating elongated discrete expanses (e.g., lines) of material having different refractive indices. For example, expanses of material **1306** may be elongated into and out of the page and may be formed in and separated by material of the substrate **1308**. In some embodiments, the elongated expanses of material **1306** may have sub-wavelength widths and pitch (e.g., widths and pitch that are smaller than the wavelengths of light that the light collimators **1302** are configured to receive from the associated light emitters **1044**). In some embodiments, the pitch **1304** may be 30-300 nm, the depth of the grating may be 10-1000 nm, the refractive index of the material forming the substrate **1308** may be 1.5-3.5, and the refractive index of the material forming the grating features **1306** may be 1.5-2.5 (and different from the refractive index of the material forming the substrate **1308**).

The illustrated grating structure may be formed by various methods. For example, the substrate **1308** may be etched or

nano-imprinted to define trenches, and the trenches may be filled with material of a different refractive index from the substrate **1308** to form the grating features **1306**.

Advantageously, nano-lens arrays may provide various benefits. For example, the light collection efficiencies of the nano-lenslets may be large, e.g., 80-95%, including 85-90%, with excellent reductions in angular emission profiles, e.g., reductions to 30-40° (from 180°). In addition, low levels of cross-talk may be achieved, since each of the nano-lens light collimators **1302** may have physical dimensions and properties (e.g., pitch, depth, the refractive indices of materials forming the feature **1306** and substrate **1308**) selected to act on light of particular colors and possibly particular angles of incidence, while preferably providing high extinction ratios (for wavelengths of light of other colors). In addition, the nano-lens arrays may have flat profiles (e.g., be formed on a flat substrate), which may facilitate integration with micro-displays that may be flat panels, and may also facilitate manufacturing and provide high reproducibility and precision in forming the nano-lens array. For example, highly reproducible trench formation and deposition processes may be used to form each nano-lens. Moreover, these processes allow, with greater ease and reproducibility, for variations between nano-lenses of an array than are typically achieved when forming curved lens with similar variations.

With reference now to FIG. **28**, a perspective view of an example of an emissive micro-display **1030** is illustrated. It will be appreciated that the light collimator arrays **1300** advantageously allow light emitted from a micro-display to be routed as desired. As result, in some embodiments, the light emitters of a full-color micro-display may be organized as desired, e.g., for ease of manufacturing or implementation in the display device. In some embodiments, the light emitters **1044** may be arranged in rows or columns **1306a**, **1306b**, **1306c**. Each row or column may include light emitters **1044** configured to emit light of the same component color. In displays where three component colors are utilized, there may be groups of three rows or columns which repeat across the micro-display **1030**. It will be appreciated that where more component colors are utilized, each repeating group may have that number of rows or columns. For example, where four component colors are utilized, each group may have four rows or four columns, with one row or one column formed by light emitters configured to emit light of a single component color.

In some embodiments, some rows or columns may be repeated to increase the number of light emitters of a particular component color. For example, light emitters of some component colors may occupy multiple rows or columns. This may facilitate color balancing and/or may be utilized to address differential aging or reductions in light emission intensity over time.

With reference to FIGS. **27** and **28**, in some embodiments, the light emitters **1044** may each have an associated light collimator **1302**. In some other embodiments, each line **1306a**, **1306b**, **1306c** of multiple light emitters **1044** may have a single associated light collimator **1302**. That single associated light collimator **1302** may extend across substantially the entirety of the associated line **1306a**, **1306b**, or **1306c**. In some other embodiments, the associated light collimator **1302** may be elongated and extend over a plurality of light emitters **1044** forming a portion of an associated line **1306a**, **1306b**, or **1306c**, and multiple similar light collimators **1302** may be provided along each of the associated lines **1306a**, **1306b**, **1306c**.

With continued reference to FIG. **28**, each light emitter **1044** may be elongated along a particular axis (e.g., along

the y-axis as illustrated); that is, each light emitter has a length along the particular axis, the length being longer than a width of the light emitter. In addition, a set of light emitters configured to emit light of the same component color may be arranged in a line **1306a**, **1306b**, or **1306c** (e.g. a row or column) extending along an axis (e.g., the x-axis) which crosses (e.g., is orthogonal to) the light emitter **1044**'s elongate axis. Thus, in some embodiments, light emitters **1044** of the same component color form a line **1306a**, **1306b**, or **1306c** of light emitters, with the line extending along a first axis (e.g., the x-axis), and with individual light emitters **1044** within the line elongated along a second axis (e.g., the y-axis).

In contrast, it will be appreciated that full-color micro-display typically include sub-pixels of each component color, with the sub-pixels arranged in particular relatively closely-packed spatial orientations in groups, with these groups reproduced across an array. Each group of sub-pixels may form a pixel in an image. In some cases, the sub-pixels are elongated along an axis, and rows or columns of sub-pixels of the same component color extend along that same axis. It will be appreciated that such an arrangement allows the sub-pixels of each group to be located close together, which may have benefits for image quality and pixel density. In the illustrated arrangement of FIG. **28**, however, sub-pixels of different component colors are relatively far apart, due to the elongate shape of the light emitters **1044**; that is, the light emitters of the line **1306a** are relatively far apart from the light emitters of the line **1306c** since the elongated shape of the light emitters of the line **1306b** causes the light emitters **1306a** and **1306c** to be spaced out more than neighboring light emitters of a given line of light emitters. While this may be expected to provide unacceptably poor image quality if the image formed on the surface of the micro-display **1030** was directly relayed to a user's eye, the use of the light collimator array **1300** advantageously allows light of different colors to be routed as desired to form a high quality image. For example, light of each component color may be used to form separate monochrome images which are then routed to and combined in an eyepiece, such as the eyepiece **1020** (e.g., FIGS. **11A** and **12-14**).

With reference to FIGS. **27** and **28**, in some embodiments, the light emitters **1044** may each have an associated light collimator **1302**. In some other embodiments, each line **1306a**, **1306b**, **1306c** of light emitters **1044** may have a single associated light collimator **1302**. That single associated light collimator **1302** may extend across substantially the entirety of the associated line **1306a**, **1306b**, or **1306c**. In some other embodiments, the associated light collimator **1302** may be elongated and extend over a plurality of light emitters **1044** forming a portion of an associated line **1306a**, **1306b**, or **1306c**, and multiple similar light collimators **1302** may be provided along each of the associated lines **1306a**, **1306b**, **1306c**.

It will be appreciated that the light collimators **1302** may be utilized to direct light along different light paths to form multi-pupil projection systems. For example, the light collimators **1302** may direct light of different component colors to two or three areas, respectively, for light uncoupling.

FIG. **29** illustrates an example of a wearable display system with the full-color emissive micro-display **1030** of FIG. **28** used to form a multi-pupil projection system **1010**. In the illustrated embodiment, the full-color emissive micro-display **1030** emits light of three component colors and forms a three-pupil projection system **1010**. The projection system **1010** has three exit pupils through which image light

1032a, **1032b**, **1032c** of different component colors propagates to three laterally-shifted light in-coupling optical elements **1022a**, **1022b**, **1022c**, respectively, of an eyepiece **1020**. The eyepiece **1020** then relays the image light **1032a**, **1032b**, **1032c** to the eye **210** of a user.

The emissive-micro-display **1030** includes an array of light emitters **1044**, which may be subdivided into monochrome light emitters **1044a**, **1044b**, **1044c**, which emit the image light **1032a**, **1032b**, **1032c**, respectively. It will be appreciated that the light emitters **1044** emit image light with a broad angular emission profile **1046**. The image light propagates through the array **1300** of light collimators, which reduces the angular emission profile to the narrowed angular emission profile **1047**.

In addition, the array of **1300** of light collimators is configured to redirect the image light (image light **1032a**, **1032b**, **1032c**) such that the image light is incident on the projection optics **1070** at angles which cause the projection optics **1070** to output the image light such that the image light propagates to the appropriate in-coupling optical element **1022a**, **1022b**, **1022c**. For example, the **1300** array of light collimators is preferably configured to: direct the image light **1032a** such that it propagates through the projection optics **1070** and is incident on the in-coupling optical element **1022a**; direct the image light **1032b** such that it propagates through the projection optics **1070** and is incident on the in-coupling optical element **1022b**; and direct the image light **1032c** such that it propagates through the projection optics **1070** and is incident on the in-coupling optical element **1022c**.

Since different light emitters **1044** may emit light of different wavelengths and may need to be redirected into different directions to reach the appropriate in-coupling optical element, in some embodiments, the light collimators associated with different light emitters **1044** may have different physical parameters (e.g., different pitches, different widths, etc.). Advantageously, the use of flat nano-lenses as light collimators facilitates the formation of light collimators which vary in physical properties across the array **1300** of light collimators. As noted herein, the nano-lenses may be formed using patterning and deposition processes, which facilitates the formation of structures with different pitches, widths, etc. across a substrate.

With reference again to FIG. **24A**, it will be appreciated that the illustrated display system shows a single emissive micro-display and omits an optical combiner **1050** (FIGS. **11A** and **12-13B**). In embodiments utilizing an optical combiner **1050**, the reflective surfaces **1052**, **1054** (FIGS. **11A**, **12-13B**, and **30B**) in the optical combiner **1050** are preferably specular reflectors, and light from the light emitters **1044** would be expected to retain their large angular emission profiles after being reflected from the reflective surfaces **1052**, **1054**. Thus, the problems with wasted light shown in FIG. **24A** are similarly present when an optical combiner **1050** is utilized.

With reference now to FIG. **30A**, an example of a wearable display system with an emissive micro-display and an associated array of light collimators is illustrated. FIG. **30A** shows additional details regarding the interplay between the light emitters **1044**, the light collimators **1302**, and the in-coupling optical elements of the eyepiece **1020**. The display system includes a micro-display **1030b**, which may be a full-color micro-display in some embodiments. In some other embodiments, the micro-display **1030b** may be a monochrome micro-display and additional monochrome

micro-displays (not shown) may be provided at different faces of the optional optical combiner **1050** (as shown in FIG. **30C**).

With continued reference to FIG. **30A**, the micro-display **1030b** includes an array of light emitters **1044**, each of which emits light with a wide angular emission profile (e.g., a Lambertian angular emission profile). Each light emitter **1044** has an associated, dedicated light collimator **1302** which effectively narrows the angular emission profile to a narrowed angular remission profile **1047**. Light beams **1032b** with the narrowed angular emission profiles pass through the projection optics **1070**, which projects or converges those light beams onto the in-coupling optical element **1022b**. It will be appreciated that the light beams **1032b** have a certain cross-sectional shape and size **1047a**. In some embodiments, the in-coupling optical element **1022b** has a size and shape which substantially matches or is larger than the cross-sectional shape and size of the light beam **1032b**, when that beam **1032b** is incident on that in-coupling optical element **1022b**. Thus, in some embodiments, the size and shape of the in-coupling optical element **1022b** may be selected based upon the cross-sectional size and shape of the light beam **1032b** when incident on the in-coupling optical element **1022b**. In some other embodiments, other factors (re-bounce mitigation, or the angles or field of view supported by the in-coupling optical elements **1022b**) may be utilized to determine the size and shape of the in-coupling optical element **1022b**, and the light collimator **1302** may be configured (e.g., sized and shaped) to provide the light beam **1032b** with an appropriately sized and shaped cross-section, which is preferably fully or nearly fully encompassed by the size and shape of the in-coupling optical element **1022b**. In some embodiments, physical parameters for the light collimator **1302** and the in-coupling optical element **1022b** may be mutually modified to provide highly efficient light utilization in conjunction with other desired functionality (e.g., re-bounce mitigation, support for the desired fields of view, etc.). Advantageously, the above-noted light collimation provided by the light collimator **1302**, and matching of the cross-sectional size and shape of the light beam **1032b** with the size and shape of the in-coupling optical element **1022b** allows the in-coupling optical element **1022b** to capture a large percentage of the incident light beam **1032b**. The in-coupled light then propagates through the waveguide **1020b** and is out-coupled to the eye **210**.

As illustrated, the micro-display **1030b** may comprise an array **1042** of light emitters **1044**, each surrounded by non-light-emitting areas **1045** having a total width **1045w**. In addition, the light emitters **1044** have a width **W** and a pitch **P**. In arrays in which the light emitters **1044** are regularly spaced, each light emitter **1044** and surrounding area **1045** effectively forms a unit cell having the width **1045w**, which may be equal to the pitch **P**.

In some embodiments, the light collimators **1302** are micro-lenses disposed directly on and surrounding associated light emitters **1044**. In some embodiments, the width of the micro-lenses **1302** is equal to **1045w**, such that neighboring micro-lenses **1302** nearly contact or directly contact one another. It will be appreciated that light from the light emitters **1044** may fill the associated micro-lens **1302**, effectively magnifying the area encompassed by the light emitter **1044**. Advantageously, such a configuration reduces the perceptibility of the areas **1045** which do not emit light and may otherwise be visible as dark spaces to a user. However, because micro-lens **1302** effectively magnifies the

associated light emitter **1044** such that it extends across the entire area of the micro-lens **1302**, the areas **1045** may be masked.

With continued reference to FIG. **30A**, the relative sizes of the light emitters **1044** and light collimators **1302** may be selected such that light from the light emitters **1044** fills the associated light collimators **1302**. For example, the light emitters **1044** may be spaced sufficiently far apart such that micro-lens collimators **1302** having the desired curvature may be formed extending over individual ones of the light emitters **1044**. In addition, as noted above, the size and shape of the intra-coupling optical element **1022b** is preferably selected such that it matches or exceeds the cross-sectional shape and size of the light beam **1032b** when incident on that in-coupling optical element **1022b**. Consequently, in some embodiments, a width **1025** of the in-coupling optical element **1022b** is equal to or greater than the width of the micro-lens **1302** (which may have a width equal to **1045_w** or **P**). Preferably, the width **1025** is greater than the width of the micro-lens **1302**, or **1045_w** or **P**, to account for some spread in the light beam **1032b**. As discussed herein, the width **1025** may also be selected to mitigate rebound and may be shorter than the length (which is orthogonal to the width) of the in-coupling optical element **1022b**. In some embodiments, the width **1025** may extend along the same axis as the direction of propagation of incoupled light **1032b** through the waveguide **1020b** before being out-coupled for propagation to the eye **210**.

With reference now to FIG. **30B**, an example of a light projection system **1010** with multiple emissive micro-displays **1030a**, **1030b**, **1030c**, and associated arrays **1300a**, **1300b**, **1300c** of light collimators, respectively, is illustrated. The angular emission profiles of light emitted by the micro-displays **1030a**, **1030b**, **1030c** are narrowed by the light collimator arrays **1300a**, **1300b**, **1300c**, thereby facilitating the collection of a large percentage of the emitted light by the projection optics **1070** after the light propagates through the optical combiner **1050**. The projection optics **1070** then directs the light to an eyepiece such as the eyepiece **1020** (e.g., FIGS. **11A** and **12-14**) (not shown).

FIG. **30C** illustrates an example of a wearable display system with multiple emissive micro-displays **1030a**, **1030b**, **1030c**, each with an associated array **1300a**, **1300b**, **1300c**, respectively, of light collimators. The illustrated display system includes a plurality of micro-displays **1030a**, **1030b**, **1030c** for emitting light with image information. As illustrated, the micro-displays **1030a**, **1030b**, **1030c** may be micro-LED panels. In some embodiments, the micro-displays may be monochrome micro-LED panels, each configured to emit a different component color. For example, the micro-display **1030a** may be configured to emit light **1032a** which is red, the micro-display **1030b** may be configured to emit light **1032b** which is green, and the micro-display **1030c** may be configured to emit light **1032c** which is blue.

Each micro-display **1030a**, **1030b**, **1030c** may have an associated array **1300a**, **1300b**, **1300c**, respectively, of light collimators. The light collimators narrow the angular emission profile of light **1032a**, **1032b**, **1032c** from light emitters of the associated micro-display. In some embodiments, individual light emitters have a dedicated associated light collimator (as shown in FIG. **30A**).

With continued reference to FIG. **30C**, the arrays **1300a**, **1300b**, **1300c** of light collimators are between the associated micro-displays **1030a**, **1030b**, **1030c** and the optical combiner **1050**, which may be an X-cube. As illustrated, the optical combiner **1050** has internal reflective surfaces **1052**, **1054** for reflecting incident light out of an output face of the

optical combiner. In addition to narrowing the angular emission profile of incident light, the arrays **1300a**, **1300c** of light collimators may be configured to redirect light from associated micro-displays **1030a**, **1030c** such that the light strikes the internal reflective surfaces **1052**, **1054** of the optical combiner **1050** at angles appropriate to propagate towards the associated light in-coupling optical elements **1022a**, **1022c**, respectively. In some embodiments, in order to redirect light in a particular direction, the arrays **1300a**, **1300c** of light collimators may comprise micro-lens or reflective wells, which may be asymmetrical and/or the light emitters may be disposed off-center relative to the micro-lens or reflective wells, as disclosed herein.

With continued reference to FIG. **30C**, projection optics **1070** (e.g., projection lens) is disposed at the output face of the optical combiner **1050** to receive image light exiting from that optical combiner. The projection optics **1070** may comprise lenses configured to converge or focus image light onto the eyepiece **1020**. As illustrated, the eyepiece **1020** may comprise a plurality of waveguides, each of which is configured to in-couple and out-couple light of a particular color. For example, waveguide **1020a** may be configured to receive red light **1032a** from the micro-display **1030a**, waveguide **1020b** may be configured to receive green light **1032b** from the micro-display **1030b**, and waveguide **1020c** may be configured to receive blue light **1032c** from the micro-display **1030c**. Each waveguide **1020a**, **1020b**, **1020c** has an associated light in-coupling optical elements **1022a**, **1022b**, **1022c**, respectively, for in coupling light therein. In addition, as discussed herein, the waveguides **1020a**, **1020b**, **1020c** may correspond to the waveguides **670**, **680**, **690**, respectively, of FIG. **9B** and may each have associated orthogonal pupil expanders (OPE's) and exit pupil expanders (EPE's), which ultimately out-couple the light **1032a**, **1032b**, **1032c** to a user.

As discussed herein, the wearable display system incorporating micro-displays is preferably configured to output light with different amounts of wavefront divergence, to provide comfortable accommodation-vergence matching for the user. These different amounts of wavefront divergence may be achieved using out-coupling optical elements with different optical powers. As discussed herein, the out-coupling optical elements may be present on or in waveguides of an eyepiece such as the eyepiece **1020** (e.g., FIGS. **11A** and **12-14**). In some embodiments, lenses may be utilized to augment the wavefront divergence provided by the out-couple optical elements or may be used to provide the desired wavefront divergence in configurations where the out-couple optical elements are configured to output collimated light.

FIGS. **31A** and **31B** illustrate examples of eyepieces **1020** having lens for varying the wavefront divergence of light to a viewer. FIG. **31A** illustrates an eyepiece **1020** having a waveguide structure **1032**. In some embodiments, as discussed herein, light of all component colors may be in-coupled into a single waveguide, such that the waveguide structure **1032** includes only the single waveguide. This advantageously provides for a compact eyepiece. In some other embodiments, the waveguide structure **1032** may be understood to include a plurality of waveguides (e.g., the waveguides **1032a**, **1032b**, **1032c** of FIGS. **11A** and **12-13A**), each of which may be configured to relay light of a single component color to a user's eye.

In some embodiments, the variable focus lens elements **1530**, **1540** may be disposed on either side of the waveguide structure **1032**. The variable focus lens elements **1530**, **1540** may be in the path of image light from the waveguide

structure **1032** to the eye **210**, and also in the path of light from the ambient environment through the waveguide structure **1003 2** to the eye **210**. The variable focus optical element **1530** may modulate the wavefront divergence of image light outputted by the waveguide structure **1032** to the eye **210**. It will be appreciated that the variable focus optical element **1530** may have optical power which may distort the eye **210**'s view of the world. Consequently, in some embodiments, a second variable focus optical element **1540** may be provided on the world side of the waveguide structure **1032**. The second variable focus optical element **1540** may provide optical power opposite to that of the variable focus optical element **1530** (or opposite to the net optical power of the optical element **1530** and the waveguide structure **1032**, where the waveguide structure **1032** has optical power), so that the net optical power of the variable focus lens elements **1530**, **1540** and the waveguide structure **1032** is substantially zero.

Preferably, the optical power of the variable focus lens elements **1530**, **1540** may be dynamically altered, for example, by applying an electrical signal thereto. In some embodiments, the variable focus lens elements **1530**, **1540** may comprise a transmissive optical element such as a dynamic lens (e.g., a liquid crystal lens, an electro-active lens, a conventional refractive lens with moving elements, a mechanical-deformation-based lens, an electrowetting lens, an elastomeric lens, or a plurality of fluids with different refractive indices). By altering the variable focus lens elements' shape, refractive index, or other characteristics, the wavefront of incident light may be changed. In some embodiments, the variable focus lens elements **1530**, **1540** may comprise a layer of liquid crystal sandwiched between two substrates. The substrates may comprise an optically transmissive material such as glass, plastic, acrylic, etc.

In some embodiments, in addition or as alternative to providing variable amounts of wavefront divergence for placing virtual content on different depth planes, the variable focus lens elements **1530**, **1540** and waveguide structure **1032** may advantageously provide a net optical power equal to the user's prescription optical power for corrective lenses. Thus, the eyepiece **1020** may serve as a substitute for lenses used to correct for refractive errors, including myopia, hyperopia, presbyopia, and astigmatism. Further details regarding the use of variable focus lens elements as substitutes for corrective lenses may be found in U.S. application Ser. No. 15/481,255, filed Apr. 6, 2017, the entire disclosure of which is incorporated by reference herein.

With reference now to FIG. **31B**, in some embodiments, the eyepiece **1020** may include static, rather than variable, lens elements. As with FIG. **31B**, the waveguide structure **1032** may include a single waveguide (e.g., which may relay light of different colors) or a plurality of waveguides (e.g., each of which may relay light of a single component color). Similarly, the waveguide structure **1034** may include a single waveguide (e.g., which may relay light of different colors) or a plurality of waveguides (e.g., each of which may relay light of a single component color). The one or both of the waveguide structures **1032**, **1034** may have optical power and may output light with particular amounts of wavefront divergence, or may simply output collimated light.

With continued reference to FIG. **31B**, the eyepiece **1020** may include static lens elements **1532**, **1534**, **1542** in some embodiments. Each of these lens elements are disposed in the path of light from the ambient environment through waveguide structures **1032**, **1034** into the eye **210**. In addition, the lens element **1532** is between a waveguide

structure **1003 2** and the eye **210**. The lens element **1532** modifies a wavefront divergence of light outputted by the waveguide structure **1032** to the eye **210**.

The lens element **1534** modifies a wavefront divergence of light outputted by the waveguide structure **1034** to the eye **210**. It will be appreciated that the light from the waveguide structure **1034** also passes through the lens element **1532**. Thus, the wavefront divergence of light outputted by the waveguide structure **1034** is modified by both the lens element **1534** and the lens element **1532** (and the waveguide structure **1032** in cases where the waveguide structure **1003 2** has optical power). In some embodiments, the lens elements **1532**, **1534** and the waveguide structure **1032** provide a particular net optical power for light outputted from the waveguide structure **1034**.

The illustrated embodiment provides two different levels of wavefront divergence, one for light outputted from the waveguide structure **1032** and a second for light outputted by a waveguide structure **1034**. As a result, virtual objects may be placed on two different depth planes, corresponding to the different levels of wavefront divergence. In some embodiments, an additional level of wavefront divergence and, thus, an additional depth plane may be provided by adding an additional waveguide structure between lens element **1532** and the eye **210**, with an additional lens element between the additional waveguide structure and the eye **210**. Further levels of wavefront divergence may be similarly added, by adding further waveguide structures and lens elements.

With continued reference to FIG. **31B**, it will be appreciated that the lens elements **1532**, **1534** and the waveguide structures **1032**, **1034** provide a net optical power that may distort the users view of the world. As a result, lens element **1542** may be used to counter the optical power and distortion of ambient light. In some embodiments, the optical power of the lens element **1542** is set to negate the aggregate optical power provided by the lens elements **1532**, **1534** and the waveguide structures **1032**, **1034**. In some other embodiments, the net optical power of the lens element **1542**; the lens elements **1532**, **1534**; and the waveguide structures **1032**, **1034** is equal to a user's prescription optical power for corrective lenses.

As discussed herein, emissive micro-displays may provide very high frame rate operation. As examples, emissive micro-displays may be capable of providing frame rates of 120 Hz or more, or 240 Hz or more, or even higher frame rates. Due in part to the high frame rate capabilities of such emissive micro-displays, a wearable system may be provided with one or more emissive micro-displays that each generate distinct image frames for both left and right eyepieces of the wearable system, along with time-synchronized routing of the image frames to the appropriate one of the left and right eyepieces. Advantageously, the emissive micro-displays may be capable of frame rates that are at least multiples of the frame rate at which virtual content is presented to a user. As a result, the emissive micro-display (or one or more micro-displays where a light projection system utilizes multiple micro-displays) may have sufficient surplus frame rate capability that it may display image frames for multiple eyepieces without impacting the rate at which image frames are presented by any individual eyepiece.

As an example, one or more micro-displays with frame rates of 120 Hz or more may be configured to provide left-eye image frames at 60 Hz to a left eyepiece, while also providing right-eye image frames at 60 Hz to a right eyepiece. The micro-displays may temporally interleave the

display of left-eye and right-eye image frames, which may also be referred to as left-eye and right-eye images, respectively. As an example, the micro-displays may alternate (e.g., in a time-multiplexing scheme) between generating a left-eye image frame that is routed to a left eyepiece and a right-eye image frame that is routed to a right eyepiece. In some embodiments, the micro-displays may display multiple left-eye image frames and/or multiple right-eye image frames in succession before displaying image frames for the other eye. As discussed herein, in some embodiments, image frames for any individual eye are provided to the user at a frame rate equal to or higher than the frame rate corresponding to the flicker fusion threshold of the user. For example, the frame rate for each of the left-eye or right-eye pieces may be 60 Hz or more, or 120 Hz or more; and, as a result, the frame rate provided by the light projection system 1010 may be 120 Hz or more, or 240 Hz or more in some embodiments.

With reference now to FIG. 32, an example is illustrated of a wearable display system with a light projection system 1010 having one or more emissive micro-displays, and an optical router 3201 for selectively directing light to left and right eyepieces 1020L and 1020R, respectively. The wearable display system may be a head-mounted display system, as discussed herein. The light projection system 1010 is common to and configured to generate image frames for both the left eyepiece 1020L and the right eyepiece 1020R. The light projection system 1010 may be any of the light projection systems disclosed herein. In some embodiments, the light projection system 1010 may include one or more of, for example, micro-displays (e.g. one or more of micro-displays 1030a, 1030b, 1030c), an optical combiner (e.g. optical combiner 1050), light redirecting structures (e.g., light redirecting structures 1080a, 1080b), light collimating arrays (e.g. light collimating arrays 1300) projection optics (e.g., projection optics 1070), etc., as discussed herein with reference to, e.g., FIGS. 10A-14 and 24B-30C.

With continued reference to FIG. 32, time-multiplexed left and right eye images are generated by the light projection system 1010 (e.g., using one or more emissive micro-displays) with image light 1032LR and then de-multiplexed using the optical router 3201, which routes image light 1032L for left-eye images to left eyepiece 1020L and image light 1032R for right eye images to right eyepiece 1020R. Control electronics 3200 may be operatively coupled and in communication with the light projection system 1010 and the optical router 3201. The control electronics 3200 may be configured to receive information from the light projection system 1010 and/or the optical router 3201 (e.g. regarding their operational status) and may send commands to control the operations of the light projection system 1010 and/or the optical router 3201. In some embodiments, the control electronics 3200 may be configured to synchronize the operation of the optical router 3201 to the operation of the light projection system 1010 (e.g., so that the optical router 3201 properly de-multiplexes the time-multiplexed images from the light projection system 1010). The control electronics 3200 may include programming (e.g., instructions stored in a non-transitory medium) to perform the various actions disclosed herein, including regulating the generation of images by one or more emissive micro-displays and regulating the operation of the optical router 3201. In some embodiments, the control electronics 3200 may be part of the local processing and data module 140 (FIG. 9E) and/or the remote processing module 150 and remote data repository 160.

It will be appreciated that the left and right eyepieces 1020L and 1020R are similar to the eyepieces 1020 disclosed herein (see e.g., FIGS. 11A, 12-23C, 29-30A, and 30C-31B and the related description), the letters “L” and “R” designating the eyepieces as being left and right eyepieces, respectively. For example, the left and right eyepieces 1020L and 1020R may include a single waveguide, or one or more waveguides arranged in a stack, as discussed herein. In some embodiments, the left and right eyepieces 1020L and 1020R may include in-coupling optical elements and out-coupling optical elements, as discussed herein. In some embodiments, where the left and right eyepieces 1020L and 1020R include a stack of waveguides, the in-coupling optical elements of different waveguides may overlap and be in the same path of light from the light projection system 1010, as discussed herein. In some embodiments, at least some in-coupling optical elements may be laterally displaced (as seen in a top-down view of a major surface of the eyepiece), such that light striking the in-coupling optical element of one waveguide does not impinge on the in-coupling optical element of an underlying waveguide, as discussed herein. In some embodiments, one or more optical filters may be disposed between waveguides of a stack of waveguides to reduce the presence of unintentionally in-coupled light within waveguides, as discussed herein.

The optical router 3201 may be configured to route image light to different (e.g., left and right) eyepieces by outputting the image light along different paths (e.g. in different directions) and/or by changing one or more properties of the light such that the light interacts differently with optical structures, outside of the optical router 3201, to redirect the light into different eyepieces. In some embodiments, the light projection system 1010 may provide image light forming left-eye and right-eye image frames with different polarization states, respectively. The optical router 3201 may then utilize polarization sensitive optical structures to selectively redirect light of a particular polarization (for image frames of a particular eyepiece) in a desired direction and/or into a desired waveguide.

In some embodiments, the optical router 3201 includes a polarizer that is configured to receive image light 1032LR from the light projection system 1010 and to output a portion of the image light 1032LR having a first polarization state, while blocking light of a second polarization state. Thus, light (having multiple polarization states) from the light projection system 1010 is effectively converted into polarized light having a single polarization state. The optical router 3201 may further include a selectively activated polarization rotator that receives the polarized light and either transmits the received light without a change in polarization state, or changes the polarization state of the polarized light. In some embodiments, the optical router 3201 may include a polarization sensitive reflector (e.g., a polarization beam splitter) that directs image light of a first polarization state towards a first eyepiece (e.g., a left eyepiece 1020L) and that substantially allows light of a second polarization to pass without being reflected. The light of the second polarization state may then reach a second eyepiece (e.g., right eyepiece 1020R). In some embodiments, the optical router 3201 may include a second reflector, which may or may not be polarization sensitive and which reflects the light of the second polarization state towards the second eyepiece (e.g., right eyepiece 1020R), as discussed below regarding FIG. 33.

In some embodiments, the optical router 3201 may be configured to simply output image light 1032LR of different

polarization states along a common light path. The eyepieces **1020L** and **1020R** may include optical structures (e.g., in-coupling optical elements) which receive the image light **1032LR**. Different eyepieces may include in-coupling optical elements to in-couple different polarization states. Thus, the eyepiece into which the image light is in-coupled may depend upon the polarization state of the incident light, as discussed below regarding FIG. **34**.

With reference now to FIG. **33**, an example as illustrated of a wearable display system having an optical router **3201** that includes a polarization-sensitive reflective structure **3306** for selectively directing images along different paths to left and right eyepieces **1020L** and **1020R**, respectively. As noted therein, a light projection system **1010** generates image light **1032LR** which forms left and right-eye image frames that are selectively polarized based on whether a given image frame is a left-eye or a right-eye image frame. After being polarized, image light **1032L** for left-eye image frames are routed to left eyepiece **1020L** and image light **1032R** for right-eye image frames are routed to right-eyepiece **1020R** by the polarization-sensitive reflective structure **3306**, depending upon the selectively-applied polarization for a given image frame. In some embodiments, the polarization-sensitive reflective structure **3306** is a polarizing beam splitter (PBS). It will be appreciated that polarization-sensitive features selectively act on light having a particular polarization while being substantially transparent to light having a different polarization.

In some embodiments, polarizer **3302** may linearly polarize light passing through the polarizer **3302** and preferably provides a polarization orientation that is aligned with polarization rotator **3304** (e.g., as the performance of the polarization rotator **3304** may be improved when it receives light polarized with a particular orientation).

The polarization rotator **3304** may be selectively electrically-switchable such that, in a first state, the polarization rotator **3304** outputs light having a first polarization state and such that, in a second state, the polarization rotator **3304** outputs light having a second polarization state that is orthogonal to the first polarization state. The control electronics **3200** may control the state of the polarization rotator **3304** and may synchronize the state of the polarization rotator **3304** with the output of image light **1032LR** for left or right-eye images from the light projection system **1010**. In some embodiments, the polarization rotator **3304** may be configured to preserve the polarization of passing polarized light, when configured in the first state, and may be configured to rotate the polarization of passing polarized light by 90°, when configured in the second state. In some embodiments, the polarization rotator **3304** may rotate the polarization direction of light in both its first and second states. The polarization rotator **3304** may, as an example, include a switchable half-wave plate (HWP).

The polarization rotator **3304** is configured to change states at a sufficiently high rate to match the frame rate of images generated by the light projection system **1010**. In some embodiments, the polarization rotator **3304** is configured to change states at a rate of at least double the frame rate of images provided to a single eye of the user. Additionally, the polarization rotator **3304** may be configured to switch between first and second states in sync with the light projection system **1010**, such that light for left-eye images generated by the light projection system **1010** pass through the polarization rotator **3304** while it is in a first state and such that light for right-eye images generated by the light projection system **1010** pass through the polarization rotator **3304** while it is in a second state. In this manner, the

polarization rotator **3304** may output image light **1032L** for images for the left eyepiece **1020L** at a desired frame rate (which may be 30 Hz, 45 Hz, 60 Hz, or greater than 60 Hz) and also output image light **1032R** for images for the right eyepiece **1020R** at a desired frame rate (which may be 30 Hz, 45 Hz, 60 Hz, or greater than 60 Hz).

After passing through the polarization rotator **3304**, the polarized light propagates through an optical component that redirects the polarized image light **1032L** or **1032R** to either the left eyepiece **1020L** or the right eyepiece **1020R**, for example, depending on the polarization of the image light. As an example, the polarized light from the polarization rotator **3304** may be passed through a polarization-sensitive reflective structure **3306** (e.g. a polarization beam splitter), which may include a polarization-sensitive mirror **3308** that reflects light having a first polarization (e.g., the polarization imparted by polarizer **3302** and rotator **3304** for light **1032L** associated with left-eye images) and thereby redirects the light towards one or more in-coupling optical elements **1022L** for the left eyepiece **1020L**. The polarization-sensitive mirror **3308** may be transparent to light having a second polarization (e.g., the orthogonal polarization imparted by rotator **3304** for light **1032R** associated with right-eye images) such that the light having the second polarization passes to mirror **3310**, which in turn redirects the light towards one or more in-coupling optical elements **1022R** associated with the right eyepiece **1020R**. It will be appreciated that the mirror **3310** may simply be a reflective surface that reflects light of all polarizations. In some embodiments, the mirror **3310** may be a polarization-sensitive mirror, which may have advantages for improving the selectivity of light in-coupled to the right eyepiece **1020R**. In some embodiments, the in-coupling optical elements **1022L** and **1022R** may be polarization sensitive, which may also have advantages for preventing the unintentional in-coupling of light of undesired polarizations (e.g., to prevent the in-coupling of light for image frames intended for the other eyepiece). In some embodiments, the in-coupling optical elements **1022L**, **1022R** may be diffractive gratings. In some embodiments, the in-coupling optical elements **1022L**, **1022R** may be a metasurface and/or liquid crystal gratings.

Thus, distinct left and right-eye images generated by the light projection system **1010** may be provided to the corresponding left and right-eye eyepieces **1020L**, **1020R** by outputting light from the optical router **3201** to the corresponding eyepiece.

With reference now to FIG. **34**, in some embodiments, the optical router **3201** may be configured to simply modify a polarization of the light **1032LR** to output light **1032L** and **1032R** along a common optical path. The light **1032L** and **1032R** have different polarization states that allow downstream polarization-sensitive in-coupling optical elements to selectively in-couple light of a desired polarization into the corresponding left or right eyepiece. FIG. **34** illustrates an example of a wearable display system with an optical router **3201** that switches polarization states of incident image light, and left and right eyepieces **1020L**, **1020R** having in-coupling optical elements **1022L'**, **1022R'** that selectively in-couple light of different polarization states. In some embodiments, the in-coupling optical elements **1022L'**, **1022R'** may be diffractive gratings. In some embodiments, the in-coupling optical elements **1022L'**, **1022R'** may be a metasurface and/or liquid crystal gratings.

As illustrated, a portion of the left and right eyepieces **1020L**, **1020R** may overlap such that the left-eye in-coupling optical elements **1022L** are substantially aligned with

the right-eye in-coupling optical elements **1022R**, so that both in-coupling optical elements are in the same optical path of light outputted by the optical router **3201**. As an example, the in-coupling optical elements **1022L** and **1022R** may be located at approximately the midway point between a user's left and right eyes or may, if desired, be located towards one side of the midway point.

The in-coupling optical elements of at least one eyepiece (e.g., the left or right eyepiece) may be polarization-sensitive. Preferably, the most upstream in-coupling optical element (the first of the in-coupling optical elements that receives light from the optical router **3201**) is polarization-sensitive. FIG. **34** illustrates an example in which the left-eye in-coupling optical element **1022L** is polarization-sensitive and "upstream" of the right-eye in-coupling optical element **1022R**. In such embodiments, the left-eye in-coupling optical element **1022L** may be configured to in-couple light having a first polarization into the left eyepiece **1020L** and may be configured to pass light having a second orthogonal polarization to the right-eye in-coupling optical elements **1022R**. The right-eye in-coupling optical element **1022R** may then be configured to in-couple the remaining light (e.g., the light not in-coupled by elements **1022L**) into the right eyepiece **1020R**.

In some embodiments, the left-eye in-coupling optical element **1022L** may not in-couple all image light **1032L** of the first polarization state, such that some of this image light **1032L** may propagate to the right-eye in-coupling optical element **1022R**. Consequently, it may be advantageous to prevent in-coupling of this image light **1032L** into the right eyepiece **1020R**. In some embodiments, the right-eye in-coupling optical elements **1022R** may also be polarization-sensitive, such that the elements **1022R** selectively in-couple light **1022R** having the second polarization state to the exclusion of light **1022L** having the first polarization state. In some embodiments, an additional polarizer, which may be referred to as a clean-up polarizer, can be positioned between the left-eye in-coupling optical elements **1022L** and the right-eye in-coupling optical element **1022R**. The clean-up polarizer may help prevent cross-talk by preventing the propagation of light **1032L** to the right-eye in-coupling optical element **1022R**.

With reference to FIGS. **32-34**, it will be appreciated that the optical router **3201** may be a mechanically switchable device that directs light **1032LR** to the appropriate one of the left-eye in-coupling optical elements **1022L** or the right-eye in-coupling optical element **1022R**. For example, the optical router **3201** may be a mirror configured to assume: a first orientation that reflects light to one of the right or left eyepieces **1022L**, **1022R**; and a second orientation that reflects light to the other right or left eyepieces **1022L**, **1022R**. In some embodiments, the mirror is a MEMS mirror. In some embodiments, the mirror is a scanning mirror having a mirror attached to an actuator that moves, for example, rotates, the mirror.

As discussed herein, emissive displays such as micro-displays may provide relatively high brightness, which may compensate for any losses associated with polarizing light from the light projection system **1010** and passing the polarized light through polarization-sensitive components such as the polarization beam splitter **3310** and polarization-sensitive in-coupling optical elements such as elements **1022L'** and/or **1022R'**. Additionally, in systems that use switchable polarization to route left and right images, reliability and performance may be improved over some mechanical optical routing systems, since such polarization-

based systems may be less sensitive to mechanical disturbances than mechanical systems.

With reference now to FIGS. **11A-34**, it will be appreciated that the illustrated components of any of the wearable display systems may be supported on the frame **80** (FIG. **9E**). As such, these components may each be effectively mounted on the head of a user **90** as part of a wearable display system.

Various example embodiments of the invention are described herein. Reference is made to these examples in a non-limiting sense. They are provided to illustrate more broadly applicable aspects of the invention. Various changes may be made to the invention described and equivalents may be substituted without departing from the spirit and scope of the invention.

For example, while advantageously utilized with AR displays that provide images across multiple depth planes, the augmented reality content disclosed herein may also be displayed by systems that provide images on a single depth plane.

In addition, many modifications may be made to adapt a particular situation, material, composition of matter, process, process act, or step(s) to the objective(s), spirit, or scope of the present invention. Further, as will be appreciated by those with skill in the art that each of the individual variations described and illustrated herein has discrete components and features which may be readily separated from or combined with the features of any of the other several embodiments without departing from the scope or spirit of the present inventions. All such modifications are intended to be within the scope of claims associated with this disclosure.

The invention includes methods that may be performed using the subject devices. The methods may comprise the act of providing such a suitable device. Such provision may be performed by the user. In other words, the "providing" act merely requires the user obtain, access, approach, position, set-up, activate, power-up or otherwise act to provide the requisite device in the subject method. Methods recited herein may be carried out in any order of the recited events that is logically possible, as well as in the recited order of events.

In addition, it will be appreciated that each of the processes, methods, and algorithms described herein and/or depicted in the figures may be embodied in, and fully or partially automated by, code modules executed by one or more physical computing systems, hardware computer processors, application-specific circuitry, and/or electronic hardware configured to execute specific and particular computer instructions. For example, computing systems may include general purpose computers (e.g., servers) programmed with specific computer instructions or special purpose computers, special purpose circuitry, and so forth. A code module may be compiled and linked into an executable program, installed in a dynamic link library, or may be written in an interpreted programming language. In some embodiments, particular operations and methods may be performed by circuitry that is specific to a given function.

Further, certain embodiments of the functionality of the present disclosure are sufficiently mathematically, computationally, or technically complex that application-specific hardware or one or more physical computing devices (utilizing appropriate specialized executable instructions) may be necessary to perform the functionality, for example, due to the volume or complexity of the calculations involved or to provide results substantially in real-time. For example, a video may include many frames, with each frame having

millions of pixels, and specifically programmed computer hardware is necessary to process the video data to provide a desired image processing task or application in a commercially reasonable amount of time.

Code modules or any type of data may be stored on any type of non-transitory computer-readable medium, such as physical computer storage including hard drives, solid state memory, random access memory (RAM), read only memory (ROM), optical disc, volatile or non-volatile storage, combinations of the same and/or the like. In some embodiments, the non-transitory computer-readable medium may be part of one or more of the local processing and data module (140), the remote processing module (150), and remote data repository (160). The methods and modules (or data) may also be transmitted as generated data signals (e.g., as part of a carrier wave or other analog or digital propagated signal) on a variety of computer-readable transmission mediums, including wireless-based and wired/cable-based mediums, and may take a variety of forms (e.g., as part of a single or multiplexed analog signal, or as multiple discrete digital packets or frames). The results of the disclosed processes or process steps may be stored, persistently or otherwise, in any type of non-transitory, tangible computer storage or may be communicated via a computer-readable transmission medium.

Any processes, blocks, states, steps, or functionalities described herein and/or depicted in the attached figures should be understood as potentially representing code modules, segments, or portions of code which include one or more executable instructions for implementing specific functions (e.g., logical or arithmetical) or steps in the process. The various processes, blocks, states, steps, or functionalities may be combined, rearranged, added to, deleted from, modified, or otherwise changed from the illustrative examples provided herein. In some embodiments, additional or different computing systems or code modules may perform some or all of the functionalities described herein. The methods and processes described herein are also not limited to any particular sequence, and the blocks, steps, or states relating thereto may be performed in other sequences that are appropriate, for example, in serial, in parallel, or in some other manner. Tasks or events may be added to or removed from the disclosed example embodiments. Moreover, the separation of various system components in the embodiments described herein is for illustrative purposes and should not be understood as requiring such separation in all embodiments. It should be understood that the described program components, methods, and systems may generally be integrated together in a single computer product or packaged into multiple computer products.

Example aspects of the invention, together with details regarding material selection and manufacture have been set forth above. As for other details of the present invention, these may be appreciated in connection with the above-referenced patents and publications as well as generally known or appreciated by those with skill in the art. The same may hold true with respect to method-based aspects of the invention in terms of additional acts as commonly or logically employed.

In addition, though the invention has been described in reference to several examples optionally incorporating various features, the invention is not to be limited to that which is described or indicated as contemplated with respect to each variation of the invention. Various changes may be made to the invention described and equivalents (whether recited herein or not included for the sake of some brevity)

may be substituted without departing from the spirit and scope of the invention. In addition, where a range of values is provided, it is understood that every intervening value, between the upper and lower limit of that range and any other stated or intervening value in that stated range, is encompassed within the invention.

Also, it is contemplated that any optional feature of the inventive variations described may be set forth and claimed independently, or in combination with any one or more of the features described herein. Reference to a singular item, includes the possibility that there are plural of the same items present. More specifically, as used herein and in claims associated hereto, the singular forms “a,” “an,” “said,” and “the” include plural referents unless the specifically stated otherwise. In other words, use of the articles allow for “at least one” of the subject item in the description above as well as claims associated with this disclosure. It is further noted that such claims may be drafted to exclude any optional element. As such, this statement is intended to serve as antecedent basis for use of such exclusive terminology as “solely,” “only” and the like in connection with the recitation of claim elements, or use of a “negative” limitation. Without the use of such exclusive terminology, the term “comprising” in claims associated with this disclosure shall allow for the inclusion of any additional element—irrespective of whether a given number of elements are enumerated in such claims, or the addition of a feature could be regarded as transforming the nature of an element set forth in such claims.

Accordingly, the claims are not intended to be limited to the embodiments shown herein, but are to be accorded the widest scope consistent with this disclosure, the principles and the novel features disclosed herein.

What is claimed is:

1. A head-mounted display system comprising:

a head-mountable frame;
 a light projection system comprising an emissive micro-display, wherein the light projection system is configured to output image light comprising left-eye image light for forming left-eye images time-multiplexed with right-eye image light for forming right-eye images;
 a left eyepiece supported by the frame;
 a right eyepiece supported by the frame; and
 an optical router including a polarizer, a switchable polarization rotator and a polarization-sensitive reflector, wherein the polarizer is configured to receive the image light from the light projection system and to only output image light with a first polarization state, wherein the switchable polarization rotator is configured to receive the image light with the first polarization state and to selectively change a polarization state of the received image light to a second polarization state, wherein the polarization-sensitive reflector is configured to receive the image light from the switchable polarization rotator and to reflect image light having the first polarization state and transmit image light having the second polarization state, and
 wherein the optical router is configured to provide, at different times, the left-eye image light to the left eyepiece and the right-eye image light to the right eyepiece.

2. The head-mounted display system of claim 1, wherein the electrically-switchable polarization rotator comprises a switchable half-wave plate (HWP).

3. The head-mounted display system of claim 1, further comprising control electronics configured to synchronize:

65

generation of left-eye image images by the light projection system and routing of the left-eye image light to the left eyepiece by the optical router; and generation of the right-eye images by the light projection system and routing of the right-eye image light to the right eyepiece by the optical router,

wherein the electrically-switchable polarization rotator is synchronized, by the control electronics, with the light projection system to output left-eye image light with a first polarization state and to output right-eye image light with a second polarization different from the first polarization state.

4. The head-mounted display system of claim 1, wherein the polarization-sensitive reflector is configured to:

direct left-eye image light having one of the first and second polarization states towards the left eyepiece; and

direct right-eye image light having the other of the first and second polarization states towards the right eyepiece.

5. The head-mounted display system of claim 1, wherein the polarization-sensitive reflector comprises a polarization beam splitter.

6. The head-mounted display system of claim 1, wherein the left eyepiece comprises one or more left-eye waveguides forming a left-eye waveguide assembly, each left-eye waveguide comprising:

a left-eye in-coupling optical element configured to in-couple image light into the left-eye waveguide; and

a left-eye out-coupling optical element configured to out-couple in-coupled image light out of the left-eye waveguide, and

the right eyepiece comprises one or more right-eye waveguides forming a right-eye waveguide assembly, each right-eye waveguide comprising:

a right-eye in-coupling optical element configured to in-couple image light into the right-eye waveguide; and

a right-eye out-coupling optical element configured to out-couple in-coupled image light out of the right-eye waveguide.

7. The head-mounted display system of claim 6, wherein the left-eye waveguide assembly is configured to output the in-coupled light with variable amounts of wavefront divergence corresponding to a plurality of depth planes and wherein the right-eye waveguide assembly is configured to output the out-coupled light with variable amounts of wavefront divergence corresponding to the plurality of depth planes.

8. The head-mounted display system of claim 6, wherein the left-eye waveguide assembly comprises a first stack of waveguides, wherein the right-eye waveguide assembly comprises a second stack of waveguides, wherein the light projection system is configured to output light of a plurality of component colors, wherein each of the left-eye and right-eye waveguide assemblies comprises at least one dedicated waveguide for light of each component color.

9. The head-mounted display system of claim 1, wherein the left eyepiece comprises one or more left-eye waveguides, each left-eye waveguide comprising:

a left-eye polarization-sensitive in-coupling optical element configured to in-couple light having the first polarization state into the left-eye waveguide; and

a left-eye out-coupling optical element configured to out-couple in-coupled light out of the left-eye waveguide.

66

10. The head-mounted display system of claim 9, wherein the right eyepiece comprises:

one or more right-eye waveguides, each right-eye waveguide comprising:

a right-eye polarization-sensitive in-coupling optical element configured to in-couple light having the second polarization state into the right-eye waveguide; and

a right-eye out-coupling optical element configured to out-couple in-coupled light out of the right-eye waveguide.

11. The head-mounted display system of claim 1, wherein the emissive micro-display comprises a micro-LED display.

12. The head-mounted display system of claim 1, further comprising a plurality of emissive micro-displays, wherein each micro-LED display is a monochromatic and configured to emit light of a component color.

13. The head-mounted display system of claim 12, further comprising an X-cube prism, wherein each of the emissive micro-LED displays face a different side of the X-cube prism.

14. The head-mounted display system of claim 13, wherein each micro-LED display comprises an array of light emitters, further comprising a plurality of arrays of light collimators, wherein each micro-display has an associated array of light collimators, and wherein each array of light collimators is configured to capture and reduce an angular emission profile of light from the micro-display.

15. The head-mounted display system of claim 14, wherein the light collimators comprise micro-lenses.

16. The head-mounted display system of claim 14, wherein the light collimators comprise nano-lenses.

17. A head-mounted display system comprising:

a head-mountable frame;

a light projection system comprising an emissive micro-display, wherein the light projection system is configured to output image light comprising left-eye image light for forming left-eye images time-multiplexed with right-eye image light for forming right-eye images;

a left eyepiece supported by the frame;

a right eyepiece supported by the frame; and

an optical router configured to:

receive the image light from the light projection system, and

provide, at different times, the left-eye image light to the left eyepiece and the right-eye image light to the right eyepiece,

wherein the left eyepiece comprises one or more left-eye waveguides, each left-eye waveguide comprising:

a left-eye polarization-sensitive in-coupling optical element configured to in-couple light having the first polarization state into the left-eye waveguide; and

a left-eye out-coupling optical element configured to out-couple in-coupled light out of the left-eye waveguide,

wherein the right eyepiece comprises one or more right-eye waveguides, each right-eye waveguide comprising:

a right-eye polarization-sensitive in-coupling optical element configured to in-couple light having the second polarization state into the right-eye waveguide; and

a right-eye out-coupling optical element configured to out-couple in-coupled light out of the right-eye waveguide, and

wherein the left-eye polarization-sensitive in-coupling optical element and the right-eye polarization-sensitive in-coupling optical element are disposed in a same image light path.

18. The head-mounted display of claim 17, further comprising a cleanup polarizer disposed between the left-eye polarization-sensitive in-coupling optical element and the right-eye polarization-sensitive in-coupling optical element, wherein the cleanup polarizer is configured to:

block light not having a polarization for which the downstream polarization-sensitive in-coupling optical element is configured sensitive.
