(57) **ABSTRACT**

Embodiments of the disclosure relate to managing a com-  
munications system based on software defined networking  
(SDN) architecture. An SDN controller is provided in the  
communications system to manage a wireless distribution  
system (WDS) and a local area network (LAN) based on  
SDN architecture. The SDN controller is communicatively  
coupled to a WDS control system in the WDS and a LAN  
control system in the LAN via respective SDN control data  
plane interfaces (CDPIs). The SDN controller analyzes a  
WDS performance report and a LAN performance report  
and provides a WDS configuration instruction(s) and/or a  
LAN configuration instruction(s) to the WDS control system  
and/or the LAN control system to reconfigure a WDS  
element(s) and/or a LAN element(s) to improve quality-of-  
experiences (QoEs) of the communications system. Moni-  
toring and optimizing the WDS and the LAN based on a  
unified software-based network management platform can

(Continued)

improve performance at reduced operational costs and complexity.

PRIORITY APPLICATIONS

This application claims the benefit of priority under 35 U.S.C. § 120 of U.S. application Ser. No. 15/482,890, filed on Apr. 10, 2017, the content of which is relied upon and incorporated herein by reference in its entirety.

BACKGROUND

The disclosure relates generally to managing a communications system, and more particularly to managing a communications network, which may include a wireless distribution system (WDS) and a local area network (LAN), based on software defined networking (SDN) architecture.

Wireless customers are increasingly demanding digital data services, such as streaming video signals. At the same time, some wireless customers use their wireless communications devices in areas that are poorly serviced by conventional cellular networks, such as inside certain buildings or areas where there is little cellular coverage. One response to the intersection of these two concerns has been the use of WDSs. WDSs include remote units configured to receive and transmit communications signals to client devices within the antenna range of the remote units. WDSs can be particularly useful when deployed inside buildings or other indoor environments where the wireless communications devices may not otherwise be able to effectively receive radio frequency (RF) signals from a source.

In this regard, FIG. 1 is a schematic diagram of an exemplary heterogeneous communications system 100 including a WDS 102 and a LAN 104. The WDS 102 is configured to provide communications services to remote coverage areas 106(1)-106(N), wherein 'N' is the number of remote coverage areas. These communications services provided by the WDS 102 can include cellular services such as long-term evolution (LTE) and location-based services based on wireless solutions (Bluetooth, Wi-Fi, Global Positioning System (GPS), and others), as examples. The remote coverage areas 106(1)-106(N) may be remotely located. In this regard, the remote coverage areas 106(1)-106(N) are created by and centered on remote units 108(1)-108(N) connected to a central unit 110 (e.g., a head-end equipment, a head-end controller, or a head-end unit). The central unit 110 may be communicatively coupled to a signal source 112, for example a base transceiver station (BTS) or a baseband unit (BBU). In this regard, the central unit 110 receives WDS downlink communications signals 114D from the signal source 112 to be distributed to the remote units 108(1)-108(N). The remote units 108(1)-108(N) are configured to receive the WDS downlink communications signals 114D from the central unit 110 over a communications medium 116 to be distributed to the respective remote coverage areas 106(1)-106(N) of the remote units 108(1)-108(N). Each of the remote units 108(1)-108(N) may include an RF transmitter/receiver and a respective antenna 118(1)-118(N) operably connected to the RF transmitter/receiver to wirelessly distribute the communications services to client devices 120 within the respective remote coverage areas 106(1)-106(N). The remote units 108(1)-108(N) are also configured to receive WDS uplink communications signals 114U from the client devices 120 in the respective remote coverage areas 106(1)-106(N) to be distributed to the signal source 112. The size of each of the

remote coverage areas 106(1)-106(N) is determined by the amount of RF power transmitted by the respective remote units 108(1)-108(N), receiver sensitivity, antenna gain, and RF environment, as well as by RF transmitter/receiver sensitivity of the client devices 120. The client devices 120 usually have a fixed maximum RF receiver sensitivity, so that the above-mentioned properties of the remote units 108(1)-108(N) mainly determine the size of the respective remote coverage areas 106(1)-106(N).

In a non-limiting example, the remote coverage areas 106(1)-106(N) are also configured to be served by RF circuits 122(1)-122(N) (e.g., Wi-Fi Access Points and indoor base stations) that are collocated with the remote units 108(1)-108(N). The RF circuits 122(1)-122(N) are communicatively coupled to the LAN 104 for communicating LAN downlink communications signals 124D and LAN uplink communications signals 124U in the remote coverage areas 106(1)-106(N). In one example, the LAN 104 includes Ethernet switching circuits 126, such as Ethernet switches and/or Ethernet bridges, that are interconnected with the RF circuits 122(1)-122(N). Given that the remote units 108(1)-108(N) and the RF circuits 122(1)-122(N) may be configured to provide wireless services concurrently in the remote coverage areas 106(1)-106(N), it may be desired to manage the WDS 102 and the LAN 104 effectively and efficiently to maximize overall quality-of-experiences (QoEs) of the heterogeneous communications system 100.

No admission is made that any reference cited herein constitutes prior art. Applicant expressly reserves the right to challenge the accuracy and pertinency of any cited documents.

SUMMARY

Embodiments of the disclosure relate to managing a communications system based on software defined networking (SDN) architecture. In examples discussed herein, a communications system includes a wireless distribution system (WDS) and a local area network (LAN). An SDN controller is provided in the communications system to manage the WDS and the LAN based on SDN architecture. The SDN controller is communicatively coupled to a WDS control system in the WDS and a LAN control system in the LAN via respective SDN control data plane interfaces (CDPIs). In one aspect, the SDN controller receives a WDS performance report indicating the operational status of the WDS from the WDS control system. In another aspect, the SDN controller receives a LAN performance report indicating the operational status of the LAN from the LAN control system. The SDN controller analyzes the WDS performance report and the LAN performance report to determine whether a WDS element(s) and/or a LAN element(s) need to be reconfigured to meet predetermined quality-of-experience (QoE) targets of the communications system. Accordingly, the SDN controller provides a WDS configuration instruction(s) and/or a LAN configuration instruction(s) to the WDS control system and/or the LAN control system to reconfigure the WDS element(s) and/or the LAN element(s) to improve the QoEs of the communications system. By managing the WDS and the LAN based on the SDN architecture, it may be possible to monitor and optimize the WDS and the LAN based on a unified software-based network management platform, thus helping to improve performance of a heterogeneous communications system at reduced operational costs and complexity.

In one aspect, a communications system is provided. The communications system includes a WDS control system

communicatively coupled to a WDS. The WDS control system is configured to generate a WDS performance report. The WDS control system is also configured to reconfigure the WDS based on a WDS configuration instruction. The communications system also includes a LAN control system communicatively coupled to a LAN. The LAN control system is configured to generate a LAN performance report. The LAN control system is also configured to reconfigure the LAN based on a LAN configuration instruction. The communications system also includes an SDN controller communicatively coupled to the WDS control system and the LAN control system via a first SDN CDPI and a second SDN CDPI, respectively. The SDN controller is configured to receive the WDS performance report and the LAN performance report from the WDS control system and the LAN control system, respectively. The SDN controller is also configured to analyze the WDS performance report and the LAN performance report to determine whether QoEs of the communications system meet predefined performance targets. The SDN controller is also configured to provide the WDS configuration instruction to the WDS control system in response to determining that the WDS needs to be reconfigured to improve the QoEs of the communications system. The SDN controller is also configured to provide the LAN configuration instruction to the LAN control system in response to determining that the LAN needs to be reconfigured to improve the QoEs of the communications system.

In another aspect, a method for managing a communications system based on SDN architecture is provided. The method includes generating a WDS performance report from a WDS control system communicatively coupled to a WDS. The method also includes generating a LAN performance report from a LAN control system communicatively coupled to a LAN. The method also includes communicatively coupling an SDN controller to the WDS control system and the LAN control system via a first SDN CDPI and a second SDN CDPI to receive the WDS performance report and the LAN performance report, respectively. The method also includes analyzing the WDS performance report and the LAN performance report by the SDN controller to determine whether QoEs of the communications system meet predefined performance targets. The method also includes providing a WDS configuration instruction from the SDN controller to the WDS control system in response to determining that the WDS needs to be reconfigured to improve the QoEs of the communications system. The method also includes providing a LAN configuration instruction from the SDN controller to the LAN control system in response to determining that the LAN needs to be reconfigured to improve the QoEs of the communications system. The method also includes reconfiguring the WDS by the WDS control system based on the WDS configuration instruction. The method also includes reconfiguring the LAN by the LAN control system based on the LAN configuration instruction.

In another aspect, an SDN controller in a communications system is provided. The SDN controller is configured to receive a WDS performance report from a WDS control system communicatively coupled to the SDN controller and a WDS. The SDN controller is also configured to receive a LAN performance report from a LAN control system communicatively coupled to the SDN controller and a LAN. The SDN controller is also configured to analyze the WDS performance report and the LAN performance report to determine whether QoEs of the communications system meet predefined performance targets. The SDN controller is also configured to provide a WDS configuration instruction

to the WDS control system in response to determining that the WDS needs to be reconfigured to improve the QoEs of the communications system. The SDN controller is also configured to provide a LAN configuration instruction to the LAN control system in response to determining that the LAN needs to be reconfigured to improve the QoEs of the communications system.

Additional features and advantages will be set forth in the detailed description which follows and, in part, will be readily apparent to those skilled in the art from the description or recognized by practicing the embodiments as described in the written description and claims hereof, as well as the appended drawings.

It is to be understood that both the foregoing general description and the following detailed description are merely exemplary and are intended to provide an overview or framework to understand the nature and character of the claims.

The accompanying drawings are included to provide a further understanding of the disclosure, and are incorporated in and constitute a part of this specification. The drawings illustrate one or more embodiment(s), and together with the description serve to explain principles and operation of the various embodiments.

#### BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic diagram of an exemplary heterogeneous communications system including a wireless distribution system (WDS) and a local area network (LAN) for example;

FIG. 2 is a schematic diagram of an exemplary software defined networking (SDN) architecture that can be employed to manage a heterogeneous communications system, such as the heterogeneous communications system of FIG. 1 for example;

FIG. 3 is a schematic diagram of an exemplary communications system in which an SDN controller is configured to manage a WDS and a LAN based on SDN architecture, such as the SDN architecture of FIG. 2, for improved performance of the communications system;

FIG. 4 is a flowchart of an exemplary process that can be employed to manage the communications system of FIG. 3 based on the SDN architecture;

FIG. 5 is a schematic diagram providing an exemplary illustration of the WDS and the LAN in the communications system of FIG. 3;

FIG. 6 is a schematic diagram of an exemplary WDS, such as the WDS of FIG. 3, provided in the form of an optical fiber-based WDS and managed via the SDN architecture of FIG. 3;

FIG. 7 is a partial schematic cut-away diagram of an exemplary building infrastructure in which a WDS, such as the WDS of FIG. 6, can be managed via the SDN architecture of FIG. 3; and

FIG. 8 is a schematic diagram representation of additional detail illustrating an exemplary computer system that could be employed in a controller, including the SDN controller of FIG. 3, for managing the communications system based on the SDN architecture of FIG. 3.

#### DETAILED DESCRIPTION

Embodiments of the disclosure relate to managing a communications system based on software defined networking (SDN) architecture. In examples discussed herein, a communications system includes a wireless distribution

system (WDS) and a local area network (LAN). An SDN controller is provided in the communications system to manage the WDS and the LAN based on SDN architecture. The SDN controller is communicatively coupled to a WDS control system in the WDS and a LAN control system in the LAN via respective SDN control data plane interfaces (CDPIs). In one aspect, the SDN controller receives a WDS performance report indicating the operational status of the WDS from the WDS control system. In another aspect, the SDN controller receives a LAN performance report indicating the operational status of the LAN from the LAN control system. The SDN controller analyzes the WDS performance report and the LAN performance report to determine whether a WDS element(s) and/or a LAN element(s) need to be reconfigured to meet predetermined quality-of-experience (QoE) targets of the communications system. Accordingly, the SDN controller provides a WDS configuration instruction(s) and/or a LAN configuration instruction(s) to the WDS control system and/or the LAN control system to reconfigure the WDS element(s) and/or the LAN element(s) to improve the QoEs of the communications system. By managing the WDS and the LAN based on the SDN architecture, it may be possible to monitor and optimize the WDS and the LAN based on a unified software-based network management platform, thus helping to improve performance of a heterogeneous communications system at reduced operational costs and complexity.

Before discussing exemplary aspects of managing a heterogeneous communications system based on SDN architecture, an overview of SDN architecture is first provided with reference to FIG. 2. The discussion of specific exemplary aspects of managing a communications system including a WDS and a LAN based on SDN architecture starts below with reference to FIG. 3.

In this regard, FIG. 2 is a schematic diagram of an exemplary SDN architecture 200 that can be employed to manage a heterogeneous communications system, such as the heterogeneous communications system 100 of FIG. 1 for example. The SDN architecture 200 includes an application plane 202, a control plane 204, and a data plane 206. At the heart of the SDN architecture 200 is an SDN controller 208 located in the control plane 204. The SDN controller 208 interfaces with one or more SDN applications 210 in the application plane 202 via one or more SDN northbound interfaces (NBIs) 212, respectively. In a non-limiting example, each of the SDN applications 210 represent a respective physical network (e.g., a WDS, a LAN, etc.) managed by the SDN controller 208. The SDN applications 210 are programs that can communicate explicitly, directly, and programmatically respective network requirements and desired network QoE targets to the SDN controller 208. Each of the SDN applications 210 includes SDN application logic 214 and at least one NBI driver 216 for communicating with the SDN controller 208 via the SDN NBIs 212.

The SDN controller 208 is a logically centralized entity in charge of translating the network requirements and QoE targets received from the SDN applications 210 into network configuration instructions 218. The SDN controller 208 is configured to provide the network configuration instructions 218 to one or more network elements 220 in the data plane 206. In a non-limiting example, each of the network elements 220 represents a physical network (e.g., a WDS, a LAN, etc.). As such, the SDN controller 208 is further configured to present the network elements 220 to the SDN applications 210 as abstracted views of the physical networks. The SDN controller 208 includes at least one NBI agent 222 configured to communicate with the NBI driver

216 via the SDN NBIs 212. The SDN controller 208 also includes SDN control logic 224, which can be provided as a microcontroller, a microprocessor, or a field programmable gate array (FPGA) for example. The SDN control logic 224 may include memory and/or other types of storage media for storing the network requirements and QoE targets received from the SDN applications 210. The SDN controller 208 also includes at least one CDPI driver 226 for communicating with the network elements 220 via one or more SDN CDPIs 228.

Each of the network elements 220 includes an SDN datapath 230. In a non-limiting example, the SDN datapath 230 is a logical network device that can encompass all or a subset of the physical network (e.g., a WDS, a LAN, etc.). The SDN datapath 230 includes a CDPI agent 232 for communicating with the SDN controller 208 via the SDN CDPIs 228. The SDN datapath 230 may also include at least one forwarding engine/processing function 234 for processing the network configuration instructions 218 and configuring the physical network encompassed by the SDN datapath 230.

The SDN architecture 200 provides a unified software-based platform that can be employed and flexibly configured to manage a heterogeneous communications network. As is further discussed below, the SDN architecture 200 can be employed to manage a communications system including a WDS and a LAN, thus helping to improve performance of the communications system at reduced operational costs and complexity.

In this regard, FIG. 3 is a schematic diagram of an exemplary communications system 300 in which an SDN controller 302 is configured to manage a WDS 304 and a LAN 306 based on SDN architecture 308, such as the SDN architecture 200 of FIG. 2, for improved performance of the communications system 300. The SDN architecture 308 includes an SDN data plane 310, an SDN control plane 312, and an SDN application plane 314 that can be functionally equivalent to the data plane 206, the control plane 204, and the application plane 202 of FIG. 2, respectively. The SDN data plane 310 includes a WDS control system 316 and a LAN control system 318 that are functionally equivalent to the SDN datapath 230 of FIG. 2. The WDS control system 316 is communicatively coupled to the WDS 304. The WDS control system 316 is configured to generate a WDS performance report 320 indicating the operational status and QoE measurements of the WDS 304. The LAN control system 318 is communicatively coupled to the LAN 306. The LAN control system 318 is configured to generate a LAN performance report 322 indicating the operational status and QoE measurements of the LAN 306.

The SDN controller 302 is provided in the SDN control plane 312 and is functionally equivalent to the SDN controller 208 of FIG. 2. The SDN controller 302, which can be implemented as a microprocessor, a microcontroller, or an FPGA for example, is communicatively coupled to the WDS control system 316 via a first SDN CDPI 324 and to the LAN control system 318 via a second SDN CDPI 326. The SDN controller 302 is communicatively coupled to a WDS application 328 and a LAN application 330 that are located in the SDN application plane 314. The WDS application 328 and the LAN application 330 are functionally equivalent to the SDN applications 210 of FIG. 2. In this regard, the WDS application 328 is configured to communicate WDS network requirements and QoE targets 332 to the SDN controller 302. Likewise, the LAN application 330 is configured to communicate LAN network requirements and QoE targets 334 to the SDN controller 302. The SDN application plane

**314** may further include a system application **336** configured to communicate network requirements and QoE targets **338** of the communications system **300** to the SDN controller **302**. The SDN controller **302** may store the WDS network requirements and QoE targets **332**, the LAN network requirements and QoE targets **334**, and the network requirements and QoE targets **338** of the communications system **300** in such storage media as memory, flash drive, solid state hard drive, etc.

With continuing reference to FIG. 3, the SDN controller **302** receives the WDS performance report **320** from the WDS control system **316** and the LAN performance report **322** from the LAN control system **318**. The SDN controller **302** analyzes the WDS performance report **320** and the LAN performance report **322** to determine whether QoEs of the communications system **300** meet predefined performance targets. In a non-limiting example, the predefined performance targets can include network throughput, network capacity, connection count, coverage area RF performance, coverage area interference level, downlink and uplink signal-to-noise ratios (SNRs), call drop rate, handover failure rate, and so on.

The SDN controller **302** provides a WDS configuration instruction **340** to the WDS control system **316** in response to determining that the WDS **304** needs to be reconfigured to improve the QoEs of the communications system **300**. In response to receiving the WDS configuration instruction **340**, the WDS control system **316** reconfigures the WDS **304** based on the WDS configuration instruction **340**. In a non-limiting example, the WDS control system **316** is configured to provide the WDS performance report **320** to the SDN controller **302** and receive the WDS configuration instruction **340** from the SDN controller **302** via the first SDN CDPI **324**. Similarly, the SDN controller **302** provides a LAN configuration instruction **342** to the LAN control system **318** in response to determining that the LAN **306** needs to be reconfigured to improve the QoEs of the communications system **300**. In response to receiving the LAN configuration instruction **342**, the LAN control system **318** reconfigures the LAN **306** based on the LAN configuration instruction **342**. In a non-limiting example, the LAN control system **318** is configured to provide the LAN performance report **322** to the SDN controller **302** and receive the LAN configuration instruction **342** from the SDN controller **302** via the second SDN CDPI **326**. By managing the communications system **300** based on the SDN architecture **308**, it is possible to monitor and adjust both the WDS **304** and the LAN **306** from a unified software-based platform, thus helping to improve overall performance of the communications system **300** at reduced operational costs and complexity.

The communications system **300** can be managed based on the SDN architecture **308** according to a process. In this regard, FIG. 4 is a flowchart of an exemplary process **400** that can be employed to manage the communications system **300** of FIG. 3 based on the SDN architecture **308**.

With reference to FIG. 4, the WDS control system **316** that is communicatively coupled to the WDS **304** is configured to generate the WDS performance report **320** (block **402**). The LAN control system **318** that is communicatively coupled to the LAN **306** is configured to generate the LAN performance report **322** (block **404**). The SDN controller **302** is communicatively coupled to the WDS control system **316** and the LAN control system **318** via the first SDN CDPI **324** and the second SDN CDPI **326** to receive the WDS performance report **320** and the LAN performance report **322**, respectively (block **406**). The SDN controller **302**

analyzes the WDS performance report **320** and the LAN performance report **322** to determine whether the QoEs of the communications system **300** meet the predefined performance targets (block **408**). The SDN controller **302** provides the WDS configuration instruction **340** to the WDS control system **316** in response to determining that the WDS **304** needs to be reconfigured to improve the QoEs of the communications system **300** (block **410**). The SDN controller **302** provides the LAN configuration instruction **342** to the LAN control system **318** in response to determining that the LAN **306** needs to be reconfigured to improve the QoEs of the communications system **300** (block **412**). The WDS control system **316** reconfigures the WDS **304** based on the WDS configuration instruction **340** (block **414**). The LAN control system **318** reconfigures the LAN **306** based on the LAN configuration instruction **342** (block **416**).

With reference back to FIG. 3, the WDS **304** includes one or more WDS circuits that the WDS control system **316** can reconfigure based on the WDS configuration instruction **340** to improve the QoEs of the communications system **300**. Likewise, the LAN **306** includes one or more LAN circuits that the LAN control system **318** can reconfigure based on the LAN configuration instruction **342** to improve the QoEs of the communications system **300**. In this regard, FIG. 5 is a schematic diagram providing an exemplary illustration of the WDS **304** and the LAN **306** in the communications system **300** of FIG. 3. Common elements between FIGS. 3 and 5 are shown therein with common element numbers and will not be re-described herein.

With reference to FIG. 5, the WDS **304** includes a central unit **500** communicatively coupled to a WDS signal source **502**. The central unit **500** is configured to distribute a plurality of WDS downlink communications signals **504D(1)-504D(M)** over a WDS downlink communications medium **506** and receive a plurality of WDS uplink communications signals **504U(1)-504U(M)** over a WDS uplink communications medium **508**. The WDS **304** includes a plurality of remote units **510(1)-510(M)**. Each of the remote units **510(1)-510(M)** is configured to receive a respective WDS downlink communications signal among the WDS downlink communications signals **504D(1)-504D(M)** for distribution to at least one WDS client device **512**. Each of the remote units **510(1)-510(M)** is also configured to receive a respective WDS uplink communications signal among the WDS uplink communications signals **504U(1)-504U(M)** from the WDS client device **512** for communication to the central unit **500**.

The LAN **306** includes one or more LAN circuits **514** communicatively coupled to the Internet. The LAN circuits **514** are configured to distribute a plurality of LAN downlink communications signals **516D(1)-516D(N)** and receive a plurality of LAN uplink communications signals **516U(1)-516U(N)**. In a non-limiting example, the LAN circuits **514** can include Ethernet switches, Ethernet bridges, and/or Internet Protocol (IP) routers. The LAN circuits **514** are interconnected with one or more RF circuits **518(1)-518(N)** included in the LAN **306**. In this regard, each of the RF circuits **518(1)-518(N)** is configured to receive a respective LAN downlink communications signal among the LAN downlink communications signals **516D(1)-516D(N)** for distribution to at least one LAN client device **520**. Each of the RF circuits **518(1)-518(N)** is also configured to receive a respective LAN uplink communications signal among the LAN uplink communications signals **516U(1)-516U(N)** from the LAN client device **520** for communication to the LAN circuits **514**. In a non-limiting example, the RF circuits

**518(1)-518(N)** can be Wi-Fi access points (APs), indoor base stations, and/or wireless repeaters.

The central unit **500** and/or the remote units **510(1)-510(M)** can be configured to provide the operational status and QoE measurements of the WDS **304** to the WDS control system **316**. Accordingly, the WDS control system **316** can reconfigure the central unit **500** and/or the remote units **510(1)-510(M)** based on the WDS configuration instruction **340**. Similarly, the LAN circuits **514** and/or the RF circuits **518(1)-518(N)** can be configured to provide the operational status and QoE measurements of the LAN **306** to the LAN control system **318**. Accordingly, the LAN control system **318** can reconfigure the LAN circuits **514** and/or the RF circuits **518(1)-518(N)** based on the LAN configuration instruction **342**.

In a non-limiting example, a selected remote unit **510(1)** among the remote units **510(1)-510(M)** is collocated in a coverage area **522** with a selected RF circuit **518(1)** among the RF circuits **518(1)-518(N)**. The selected remote unit **510(1)** and the selected RF circuit **518(1)** may be configured to communicate with the central unit **500** and the LAN circuits **514**, respectively, over a common optical-fiber trunk **524**. For the convenience of reference and illustration, the selected remote unit **510(1)**, the WDS client device **512**, the selected RF circuit **518(1)**, and the LAN client device **520** are discussed in the following optimization scenarios as non-limiting examples. It shall be appreciated that any combination of the remote units **510(1)-510(M)** and the RF circuits **518(1)-518(N)** can be optimized in the optimization scenarios described hereinafter.

In one example, the WDS control system **316** determines that the selected remote unit **510(1)** is out of service. Accordingly, the WDS control system **316** generates and provides the WDS performance report **320** indicating that the selected remote unit **510(1)** is out of service. In response to receiving the WDS performance report **320**, the SDN controller **302** provides the LAN configuration instruction **342** to the LAN control system **318** to reconfigure quality-of-service (QoS) parameters of the LAN **306** to increase bandwidth of the selected RF circuit **518(1)** that is collocated with the selected remote unit **510(1)** in the coverage area **522**. As a result, the WDS client device **512** can switch to receiving wireless services from the selected RF circuit **518(1)** while the selected remote unit **510(1)** is out of service.

In another example, the WDS control system **316** determines that the selected remote unit **510(1)** is powered down. Accordingly, the WDS control system **316** generates and provides the WDS performance report **320** indicating that the selected remote unit **510(1)** is powered down. In response to receiving the WDS performance report **320**, the SDN controller **302** provides the LAN configuration instruction **342** to the LAN control system **318** to reconfigure QoS parameters of the LAN **306** to increase bandwidth of the selected RF circuit **518(1)** that is collocated with the selected remote unit **510(1)** in the coverage area **522**. As a result, the WDS client device **512** can switch to receiving wireless services from the selected RF circuit **518(1)** while the selected remote unit **510(1)** is powered down.

In another example, the LAN control system **318** determines that the selected RF circuit **518(1)** is out of service. Accordingly, the LAN control system **318** generates and provides the LAN performance report **322** indicating that the selected RF circuit **518(1)** is out of service. In response to receiving the LAN performance report **322**, the SDN controller **302** provides the WDS configuration instruction **340** to the WDS control system **316** to shift capacity to the

selected remote unit **510(1)** that is collocated with the selected RF circuit **518(1)** in the coverage area **522**. As a result, the LAN client device **520** can switch to receiving wireless services from the selected remote unit **510(1)** while the selected RF circuit **518(1)** is out of service.

In another example, the WDS control system **316** determines that the selected remote unit **510(1)** has increased connection count. Accordingly, the WDS control system **316** generates and provides the WDS performance report **320** indicating that the selected remote unit **510(1)** has increased connection count. In response to receiving the WDS performance report **320**, the SDN controller **302** provides the LAN configuration instruction **342** to the LAN control system **318** to shift bandwidth allocation from the LAN **306** to the selected remote unit **510(1)**. As a result, the selected remote unit **510(1)** can adequately handle the increased connection count.

In another example, the WDS control system **316** determines that the WDS client device **512** loses RF connection from the selected remote unit **510(1)**. Accordingly, the WDS control system **316** generates and provides the WDS performance report **320** indicating that the WDS client device **512** has lost RF connection from the selected remote unit **510(1)**. In response to receiving the WDS performance report **320**, the SDN controller **302** provides the WDS configuration instruction **340** and the LAN configuration instruction **342** to the WDS control system **316** and the LAN control system **318**, respectively, to move the WDS client device **512** from the selected remote unit **510(1)** to the selected RF circuit **518(1)** that is collocated with the selected remote unit **510(1)**.

In another example, the LAN control system **318** determines that the selected RF circuit **518(1)** loses power. Accordingly, the LAN control system **318** generates and provides the LAN performance report **322** indicating that the selected RF circuit **518(1)** has lost power. In response to receiving the LAN performance report **322**, the SDN controller **302** provides the WDS configuration instruction **340** to the WDS control system **316** to shift capacity from the selected RF circuit **518(1)** to the selected remote unit **510(1)** that is collocated with the selected RF circuit **518(1)** in the coverage area **522**.

In another example, the LAN control system **318** determines that the selected RF circuit **518(1)** is over capacity. Accordingly, the LAN control system **318** generates and provides the LAN performance report **322** indicating that the selected RF circuit **518(1)** is over capacity. In response to receiving the LAN performance report **322**, the SDN controller **302** provides the WDS configuration instruction **340** and the LAN configuration instruction **342** to the WDS control system **316** and the LAN control system **318**, respectively, to move the LAN client device **520** associated with the selected RF circuit **518(1)** to the selected remote unit **510(1)** that is collocated with the selected RF circuit **518(1)** in the coverage area **522**.

In another example, the WDS control system **316** determines that the selected remote unit **510(1)** experiences interference. Accordingly, the WDS control system **316** generates and provides the WDS performance report **320** indicating that the selected remote unit **510(1)** experiences interference. In response to receiving the WDS performance report **320**, the SDN controller **302** provides the WDS configuration instruction **340** and the LAN configuration instruction **342** to the WDS control system **316** and the LAN control system **318**, respectively, to move the WDS client device **512** associated with the selected remote unit **510(1)**

to the selected RF circuit **518(1)** that is collocated with the selected remote unit **510(1)** in the coverage area **522**.

In another example, the WDS control system **316** determines that the selected remote unit **510(1)** consumes excessive power. Accordingly, the WDS control system **316** generates and provides the WDS performance report **320** indicating that the selected remote unit **510(1)** consumes excessive power. In response to receiving the WDS performance report **320**, the SDN controller **302** provides the WDS configuration instruction **340** to the WDS control system **316** to reduce power supply to less critical service antennas in the selected remote unit **510(1)**.

In another example, the LAN control system **318** determines that the selected RF circuit **518(1)** consumes excessive power. Accordingly, the LAN control system **318** generates and provides the LAN performance report **322** indicating that the selected RF circuit **518(1)** consumes excessive power. In response to receiving the LAN performance report **322**, the SDN controller **302** provides the LAN configuration instruction **342** to the LAN control system **318** to reduce power supply to less critical service antennas in the selected RF circuit **518(1)**.

In another example, the LAN control system **318** determines that the selected RF circuit **518(1)** has increased connection count. Accordingly, the LAN control system **318** generates and provides the LAN performance report **322** indicating that the selected RF circuit **518(1)** has increased connection count. In response to receiving the LAN performance report **322**, the SDN controller **302** provides the WDS configuration instruction **340** to the WDS control system **316** to shift capacity from the WDS **304** to the selected RF circuit **518(1)**.

FIG. 6 is a schematic diagram of an exemplary WDS **600**, such as the WDS **304** of FIG. 3, provided in the form of an optical fiber-based WDS and managed via the SDN architecture **308** of FIG. 3. The WDS **600** includes an optical fiber for distributing communications services for multiple frequency bands. The WDS **600** in this example is comprised of three (3) main components in this example. A plurality of radio interfaces provided in the form of radio interface modules (RIMs) **602(1)-602(M)** are provided in a central unit **604** to receive and process a plurality of WDS downlink communications signals **606D(1)-606D(R)** prior to optical conversion into WDS downlink optical fiber-based communications signals. The WDS downlink communications signals **606D(1)-606D(R)** may be received from a base station as an example. The RIMs **602(1)-602(M)** provide both downlink and uplink interfaces for signal processing. The notations “1-R” and “1-M” indicate that any number of the referenced component, 1-R and 1-M, respectively, may be provided. The central unit **604** is configured to accept the RIMs **602(1)-602(M)** as modular components that can easily be installed and removed or replaced in the central unit **604**. In one example, the central unit **604** is configured to support up to twelve (12) RIMs **602(1)-602(12)**. Each RIM **602(1)-602(M)** can be designed to support a particular type of radio source or range of radio sources (i.e., frequencies) to provide flexibility in configuring the central unit **604** and the WDS **600** to support the desired radio sources.

For example, one RIM **602** may be configured to support the Personalized Communications System (PCS) radio band. Another RIM **602** may be configured to support the 800 megahertz (MHz) radio band. In this example, by inclusion of the RIMs **602(1)-602(M)**, the central unit **604** could be configured to support and distribute communications signals on both PCS and Long-Term Evolution (LTE) **700** radio bands, as an example. The RIMs **602(1)-602(M)** may be

provided in the central unit **604** that support any frequency bands desired, including but not limited to the US Cellular band, PCS band, Advanced Wireless Service (AWS) band, 700 MHz band, Global System for Mobile communications (GSM) **900**, GSM **1800**, and Universal Mobile Telecommunications System (UMTS). The RIMs **602(1)-602(M)** may also be provided in the central unit **604** that support any wireless technologies desired, including but not limited to Code Division Multiple Access (CDMA), CDMA200, 1xRTT, Evolution—Data Only (EV-DO), UMTS, High-speed Packet Access (HSPA), GSM, General Packet Radio Services (GPRS), Enhanced Data GSM Environment (EDGE), Time Division Multiple Access (TDMA), LTE, iDEN, and Cellular Digital Packet Data (CDPD).

The RIMs **602(1)-602(M)** may be provided in the central unit **604** that support any frequencies desired, including but not limited to US FCC and Industry Canada frequencies (824-849 MHz on uplink and 869-894 MHz on downlink), US FCC and Industry Canada frequencies (1850-1915 MHz on uplink and 1930-1995 MHz on downlink), US FCC and Industry Canada frequencies (1710-1755 MHz on uplink and 2110-2155 MHz on downlink), US FCC frequencies (698-716 MHz and 776-787 MHz on uplink and 728-746 MHz on downlink), EU R & TTE frequencies (880-915 MHz on uplink and 925-960 MHz on downlink), EU R & TTE frequencies (1710-1785 MHz on uplink and 1805-1880 MHz on downlink), EU R & TTE frequencies (1920-1980 MHz on uplink and 2110-2170 MHz on downlink), US FCC frequencies (806-824 MHz on uplink and 851-869 MHz on downlink), US FCC frequencies (896-901 MHz on uplink and 929-941 MHz on downlink), US FCC frequencies (793-805 MHz on uplink and 763-775 MHz on downlink), and US FCC frequencies (2495-2690 MHz on uplink and downlink).

With continuing reference to FIG. 6, the WDS downlink communications signals **606D(1)-606D(R)** are provided to a plurality of optical interfaces provided in the form of optical interface modules (OIMs) **608(1)-608(N)** in this embodiment to convert the WDS downlink communications signals **606D(1)-606D(R)** into a plurality of WDS downlink optical fiber-based communications signals **610D(1)-610D(R)**. The notation “1-N” indicates that any number of the referenced component 1-N may be provided. The OIMs **608(1)-608(N)** may be configured to provide a plurality of optical interface components (OICs) that contain optical-to-electrical (O/E) and electrical-to-optical (E/O) converters, as will be described in more detail below. The OIMs **608(1)-608(N)** support the radio bands that can be provided by the RIMs **602(1)-602(M)**, including the examples previously described above.

The OIMs **608(1)-608(N)** each include E/O converters to convert the WDS downlink communications signals **606D(1)-606D(R)** into the WDS downlink optical fiber-based communications signals **610D(1)-610D(R)**. The WDS downlink optical fiber-based communications signals **610D(1)-610D(R)** are communicated over a downlink optical fiber-based communications medium **612D** to a plurality of remote units **614(1)-614(S)**. The notation “1-S” indicates that any number of the referenced component 1-S may be provided. Remote unit O/E converters provided in the remote units **614(1)-614(S)** convert the WDS downlink optical fiber-based communications signals **610D(1)-610D(R)** back into the WDS downlink communications signals **606D(1)-606D(R)**, which are then provided to antennas **616(1)-616(S)** in the remote units **614(1)-614(S)** to client devices in the reception range of the antennas **616(1)-616(S)**.

The remote units **614(1)-614(S)** receive a plurality of uplink RF communications signals from the client devices through the antennas **616(1)-616(S)**. The remote units **614(1)-614(S)** convert the uplink RF communications signals into a plurality of WDS uplink communications signals **618U(1)-618U(S)**. Remote unit E/O converters are also provided in the remote units **614(1)-614(S)** to convert the WDS uplink communications signals **618U(1)-618U(S)** into a plurality of WDS uplink optical fiber-based communications signals **610U(1)-610U(S)**. The remote units **614(1)-614(S)** communicate the WDS uplink optical fiber-based communications signals **610U(1)-610U(S)** over an uplink optical fiber-based communications medium **612U** to the OIMs **608(1)-608(N)** in the central unit **604**. The OIMs **608(1)-608(N)** include O/E converters that convert the received WDS uplink optical fiber-based communications signals **610U(1)-610U(S)** into a plurality of WDS uplink communications signals **620U(1)-620U(S)**, which are processed by the RIMs **602(1)-602(M)** and provided as the WDS uplink communications signals **620U(1)-620U(S)**. The central unit **604** may provide the WDS uplink communications signals **620U(1)-620U(S)** to a base station or other communications system.

Note that the downlink optical fiber-based communications medium **612D** and the uplink optical fiber-based communications medium **612U** connected to each of the remote units **614(1)-614(S)** may be a common optical fiber-based communications medium, wherein for example, wave division multiplexing (WDM) is employed to provide the WDS downlink optical fiber-based communications signals **610D(1)-610D(R)** and the WDS uplink optical fiber-based communications signals **610U(1)-610U(S)** on the same optical fiber-based communications medium.

The WDS **600** of FIG. 6 may be provided in an indoor environment, as illustrated in FIG. 7. FIG. 7 is a partial schematic cut-away diagram of an exemplary building infrastructure **700** in which a WDS, such as the WDS **600** of FIG. 6, can be managed via the SDN architecture **308** of FIG. 3. The building infrastructure **700** in this embodiment includes a first (ground) floor **702(1)**, a second floor **702(2)**, and a third floor **702(3)**. The floors **702(1)-702(3)** are serviced by a central unit **704** to provide antenna coverage areas **706** in the building infrastructure **700**. The central unit **704** is communicatively coupled to a base station **708** to receive downlink communications signals **710D** from the base station **708**. The central unit **704** is communicatively coupled to a plurality of remote units **712** to distribute the downlink communications signals **710D** to the remote units **712** and to receive uplink communications signals **710U** from the remote units **712**, as previously discussed above. The downlink communications signals **710D** and the uplink communications signals **710U** communicated between the central unit **704** and the remote units **712** are carried over a riser cable **714**. The riser cable **714** may be routed through interconnect units (ICUs) **716(1)-716(3)** dedicated to each of the floors **702(1)-702(3)** that route the downlink communications signals **710D** and the uplink communications signals **710U** to the remote units **712** and also provide power to the remote units **712** via array cables **718**.

FIG. 8 is a schematic diagram representation of additional detail illustrating an exemplary computer system **800** that could be employed in a controller, including the SDN controller **302** of FIG. 3, for managing the communications system **300** based on the SDN architecture **308**. In this regard, the computer system **800** is adapted to execute

instructions from an exemplary computer-readable medium to perform these and/or any of the functions or processing described herein.

In this regard, the computer system **800** in FIG. 8 may include a set of instructions that may be executed to predict frequency interference to avoid or reduce interference in a multi-frequency DAS. The computer system **800** may be connected (e.g., networked) to other machines in a LAN, an intranet, an extranet, or the Internet. While only a single device is illustrated, the term “device” shall also be taken to include any collection of devices that individually or jointly execute a set (or multiple sets) of instructions to perform any one or more of the methodologies discussed herein. The computer system **800** may be a circuit or circuits included in an electronic board card, such as, a printed circuit board (PCB), a server, a personal computer, a desktop computer, a laptop computer, a personal digital assistant (PDA), a computing pad, a mobile device, or any other device, and may represent, for example, a server or a user’s computer.

The exemplary computer system **800** in this embodiment includes a processing circuit or processor **802**, a main memory **804** (e.g., read-only memory (ROM), flash memory, dynamic random access memory (DRAM), such as synchronous DRAM (SDRAM), etc.), and a static memory **806** (e.g., flash memory, static random access memory (SRAM), etc.), which may communicate with each other via a data bus **808**. In a non-limiting example, the main memory **804** and/or the static memory **806** can be used to store the predefined performance targets of the QoEs of the communications system **300**. Alternatively, the processor **802** may be connected to the main memory **804** and/or the static memory **806** directly or via some other connectivity means. The processor **802** may be a controller, and the main memory **804** or the static memory **806** may be any type of memory.

The processor **802** represents one or more general-purpose processing devices, such as a microprocessor, central processing unit, or the like. More particularly, the processor **802** may be a complex instruction set computing (CISC) microprocessor, a reduced instruction set computing (RISC) microprocessor, a very long instruction word (VLIW) microprocessor, a processor implementing other instruction sets, or other processors implementing a combination of instruction sets. The processor **802** is configured to execute processing logic in instructions for performing the operations and steps discussed herein.

The computer system **800** may further include a network interface device **810**. The computer system **800** also may or may not include an input **812**, configured to receive input and selections to be communicated to the computer system **800** when executing instructions. The computer system **800** also may or may not include an output **814**, including but not limited to a display, a video display unit (e.g., a liquid crystal display (LCD) or a cathode ray tube (CRT)), an alphanumeric input device (e.g., a keyboard), and/or a cursor control device (e.g., a mouse).

The computer system **800** may or may not include a data storage device that includes instructions **816** stored in a computer-readable medium **818**. The instructions **816** may also reside, completely or at least partially, within the main memory **804** and/or within the processor **802** during execution thereof by the computer system **800**, the main memory **804** and the processor **802** also constituting computer-readable medium. The instructions **816** may further be transmitted or received over a network **820** via the network interface device **810**.

While the computer-readable medium **818** is shown in an exemplary embodiment to be a single medium, the term “computer-readable medium” should be taken to include a single medium or multiple media (e.g., a centralized or distributed database, and/or associated caches and servers) 5 that store the one or more sets of instructions. The term “computer-readable medium” shall also be taken to include any medium that is capable of storing, encoding, or carrying a set of instructions for execution by the processing device and that cause the processing device to perform any one or more of the methodologies of the embodiments disclosed herein. The term “computer-readable medium” shall accordingly be taken to include, but not be limited to, solid-state memories, optical medium, and magnetic medium. 10

The embodiments disclosed herein include various steps. The steps of the embodiments disclosed herein may be formed by hardware components or may be embodied in machine-executable instructions, which may be used to cause a general-purpose or special-purpose processor programmed with the instructions to perform the steps. Alternatively, the steps may be performed by a combination of hardware and software. 20

The embodiments disclosed herein may be provided as a computer program product, or software, that may include a machine-readable medium (or computer-readable medium) 25 having stored thereon instructions, which may be used to program a computer system (or other electronic devices) to perform a process according to the embodiments disclosed herein. A machine-readable medium includes any mechanism for storing or transmitting information in a form readable by a machine (e.g., a computer). For example, a machine-readable medium includes: a machine-readable storage medium (e.g., ROM, random access memory (“RAM”), a magnetic disk storage medium, an optical storage medium, flash memory devices, etc.); and the like. 35

Unless otherwise expressly stated, it is in no way intended that any method set forth herein be construed as requiring that its steps be performed in a specific order. Accordingly, where a method claim does not actually recite an order to be followed by its steps, or it is not otherwise specifically stated in the claims or descriptions that the steps are to be limited to a specific order, it is in no way intended that any particular order be inferred. 40

It will be apparent to those skilled in the art that various modifications and variations can be made without departing from the spirit or scope of the invention. Since modifications, combinations, sub-combinations and variations of the disclosed embodiments incorporating the spirit and substance of the invention may occur to persons skilled in the art, the invention should be construed to include everything within the scope of the appended claims and their equivalents. 50

What is claimed is:

1. A method for managing a communications system based on software defined networking (SDN) architecture, comprising: 55  
 generating a wireless distribution system (WDS) performance report from a WDS control system communicatively coupled to a WDS comprising a plurality of optical fiber-based communications media; 60  
 generating a local area network (LAN) performance report from a LAN control system communicatively coupled to a LAN;  
 communicatively coupling an SDN controller to the WDS control system and the LAN control system via a first SDN control data plane interface (CDPI) and a second 65

SDN CDPI to receive the WDS performance report and the LAN performance report, respectively;  
 analyzing the WDS performance report and the LAN performance report by the SDN controller to determine whether quality-of-experiences (QoEs) of the communications system meet predefined performance targets;  
 providing a WDS configuration instruction from the SDN controller to the WDS control system in response to determining that the WDS needs to be reconfigured to improve the QoEs of the communications system;  
 providing a LAN configuration instruction from the SDN controller to the LAN control system in response to determining that the LAN needs to be reconfigured to improve the QoEs of the communications system;  
 reconfiguring the WDS by the WDS control system based on the WDS configuration instruction;  
 reconfiguring the LAN by the LAN control system based on the LAN configuration instruction;  
 configuring the WDS control system to provide the WDS performance report to the SDN controller and receive the WDS configuration instruction from the SDN controller; and  
 configuring the LAN control system to provide the LAN performance report to the SDN controller and receive the LAN configuration instruction from the SDN controller. 10

2. The method of claim 1, further comprising:  
 determining a selected remote unit in the WDS that has increased connection count; and  
 generating the WDS performance report indicating that the selected remote unit has the increased connection count. 15

3. The method of claim 2, further comprising providing the LAN configuration instruction to the LAN control system to shift bandwidth allocation from the LAN to the selected remote unit. 20

4. The method of claim 1, further comprising:  
 determining a selected radio frequency (RF) circuit in the LAN that loses power; and  
 generating the LAN performance report indicating the selected RF circuit that loses power. 25

5. The method of claim 4, further comprising providing the WDS configuration instruction to the WDS control system to shift capacity from the selected RF circuit to a selected remote unit that is collocated with the selected RF circuit. 30

6. The method of claim 1, further comprising:  
 determining a selected radio frequency (RF) circuit in the LAN that is over capacity; and  
 generating the LAN performance report indicating that the selected RF circuit is over capacity. 35

7. The method of claim 6, further comprising providing the WDS configuration instruction and the LAN configuration instruction to the WDS control system and the LAN control system, respectively, to move a LAN client device associated with the selected RF circuit to a selected remote unit that is collocated with the selected RF circuit. 40

8. The method of claim 1, further comprising:  
 determining a selected remote unit in the WDS that consumes excessive power; and  
 generating the WDS performance report indicating the selected remote unit that consumes excessive power. 45

9. The method of claim 8, further comprising providing the WDS configuration instruction to the WDS control system to reduce power supply to selected service antennas in the selected remote unit. 50

17

10. The method of claim 1, further comprising:  
determining a selected radio frequency (RF) circuit in the  
LAN that consumes excessive power; and  
generating the LAN performance report indicating the  
selected RF circuit that consumes excessive power.

11. The method of claim 10, further comprising providing  
the LAN configuration instruction to the LAN control system  
to reduce power supply to selected service antennas in  
the selected RF circuit.

12. The method of claim 1, further comprising:  
determining a selected radio frequency (RF) circuit in the  
LAN that has increased connection count; and  
generating the LAN performance report indicating that  
the selected RF circuit has the increased connection  
count.

13. The method of claim 12, further comprising providing  
the WDS configuration instruction to the WDS control  
system to shift capacity from the WDS to the selected RF  
circuit.

14. The method of claim 1, further comprising:  
determining a selected remote unit in the WDS that has  
increased connection count;  
generating the WDS performance report indicating that  
the selected remote unit has the increased connection  
count; and  
providing the LAN configuration instruction to the LAN  
control system to shift bandwidth allocation from the  
LAN to the selected remote unit.

15. The method of claim 1, further comprising:  
determining a selected radio frequency (RF) circuit in the  
LAN that is over capacity;  
generating the LAN performance report indicating that  
the selected RF circuit is over capacity; and  
providing the WDS configuration instruction and the  
LAN configuration instruction to the WDS control  
system and the LAN control system, respectively, to  
move a LAN client device associated with the selected  
RF circuit to a selected remote unit that is collocated  
with the selected RF circuit.

16. The method of claim 1, further comprising:  
determining a selected radio frequency (RF) circuit in the  
LAN that consumes excessive power;  
generating the LAN performance report indicating the  
selected RF circuit that consumes excessive power; and  
providing the LAN configuration instruction to the LAN  
control system to reduce power supply to selected  
service antennas in the selected RF circuit.

17. The method of claim 1, further comprising:  
determining a selected radio frequency (RF) circuit in the  
LAN that has increased connection count;  
generating the LAN performance report indicating that  
the selected RF circuit has the increased connection  
count; and  
providing the WDS configuration instruction to the WDS  
control system to shift capacity from the WDS to the  
selected RF circuit.

18. A method for managing a communications system  
based on software defined networking (SDN) architecture,  
comprising:

generating a wireless distribution system (WDS) performance  
report from a WDS control system communicatively  
coupled to a WDS comprising a plurality of  
optical fiber-fiber-based communications media;  
generating a local area network (LAN) performance  
report from a LAN control system communicatively  
coupled to a LAN;

18

communicatively coupling an SDN controller to the WDS  
control system and the LAN control system via a first  
SDN control data plane interface (CDPI) and a second  
SDN CDPI to receive the WDS performance report and  
the LAN performance report, respectively;

analyzing the WDS performance report and the LAN  
performance report by the SDN controller to determine  
whether quality-of-experiences (QoEs) of the commu-  
nications system meet predefined performance targets;

providing a WDS configuration instruction from the SDN  
controller to the WDS control system in response to  
determining that the WDS needs to be reconfigured to  
improve the QoEs of the communications system;

providing a LAN configuration instruction from the SDN  
controller to the LAN control system in response to  
determining that the LAN needs to be reconfigured to  
improve the QoEs of the communications system;

reconfiguring the WDS by the WDS control system based  
on the WDS configuration instruction;  
reconfiguring the LAN by the LAN control system based  
on the LAN configuration instruction;

configuring the WDS control system to provide the WDS  
performance report to the SDN controller and receive  
the WDS configuration instruction from the SDN controller;

determining a selected radio frequency (RF) circuit in the  
LAN that loses power;

generating the LAN performance report indicating the  
selected RF circuit that loses power; and

providing the WDS configuration instruction to the WDS  
control system to shift capacity from the selected RF  
circuit to a selected remote unit that is collocated with  
the selected RF circuit.

19. A method for managing a communications system  
based on software defined networking (SDN) architecture,  
comprising:

generating a wireless distribution system (WDS) performance  
report from a WDS control system communicatively  
coupled to a WDS comprising a plurality of  
optical fiber-fiber-based communications media;

generating a local area network (LAN) performance  
report from a LAN control system communicatively  
coupled to a LAN;

communicatively coupling an SDN controller to the WDS  
control system and the LAN control system via a first  
SDN control data plane interface (CDPI) and a second  
SDN CDPI to receive the WDS performance report and  
the LAN performance report, respectively;

analyzing the WDS performance report and the LAN  
performance report by the SDN controller to determine  
whether quality-of-experiences (QoEs) of the commu-  
nications system meet predefined performance targets;

providing a WDS configuration instruction from the SDN  
controller to the WDS control system in response to  
determining that the WDS needs to be reconfigured to  
improve the QoEs of the communications system;

providing a LAN configuration instruction from the SDN  
controller to the LAN control system in response to  
determining that the LAN needs to be reconfigured to  
improve the QoEs of the communications system;

reconfiguring the WDS by the WDS control system based  
on the WDS configuration instruction;  
reconfiguring the LAN by the LAN control system based  
on the LAN configuration instruction;

configuring the WDS control system to provide the WDS  
performance report to the SDN controller and receive  
the WDS configuration instruction from the SDN con-  
troller;  
determining a selected remote unit in the WDS that 5  
consumes excessive power;  
generating the WDS performance report indicating the  
selected remote unit that consumes excessive power;  
and  
providing the WDS configuration instruction to the WDS 10  
control system to reduce power supply to selected  
service antennas in the selected remote unit.
