(54) **Title:** PROCESSING SPATIAL FEATURES

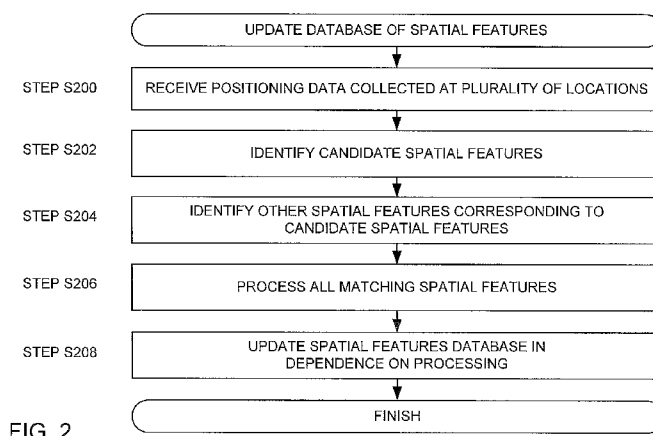

FIG. 2

(57) **Abstract:** There is disclosed a method of updating a database of spatial features, said spatial features being associated with a region, and the method comprising: receiving positioning data that has been collected at a plurality of locations within the region; processing the collected positioning data to identify at least one candidate spatial feature associated with the region; identifying at least one other spatial feature corresponding to said at least one candidate spatial feature, said at least one other spatial feature and said at least one candidate spatial feature as a whole constituting matching spatial features; processing said matching spatial features; and updating the database of spatial features in dependence on the processing of said matching spatial features.

1 PROCESSING SPATIAL FEATURES

2
3 Field of the invention

4
5 The present invention relates to (but is not limited to) autonomously identifying indoor
6 spatial features, for example by crowd-sourcing.

7
8 Background to the invention

9
10 Various methods exist to allow the user of a mobile device (such as a smartphone) to
11 estimate the location of the device. Devices may, for example, include a positioning
12 module, such as a Global Navigation Satellite System (GNSS) which provides an
13 estimate of a user's absolute position. Other systems, such as Pedometer Dead
14 Reckoning (PDR) systems, provide an estimate of the user's relative position, which
15 can be combined with previous absolute position estimates to provide a current, real-
16 time position estimate. A further class of positioning system carries out range-finding
17 on electromagnetic signals received at the device, and combines the range data with
18 predetermined information about the sources of the signals (such as their location) to
19 produce a position estimate.

20
21 The GNSS and similar systems can produce relatively accurate position estimates,
22 but are limited in that they typically do not function indoors. The relative positioning
23 systems (such as PDR) and range-finding systems (such as Wi-Fi location systems)
24 are relatively less accurate, but are typically the only systems which provide

1 meaningful results indoors. The accuracy of range-finding positioning is limited by
2 factors such as multi-path interference, attenuation by walls, and the like, which can
3 result in poor performance even when the location of electromagnetic signal sources
4 (such as Wireless Access Points, WAPs) is known precisely.

5
6 The accuracy of range-finding positioning systems can be improved by 'war-walking'
7 in the vicinity of the above-mentioned electromagnetic signal sources, so as to assist
8 in mapping particular received signals to a particular location within a building. This
9 can be done as part of a 'crowd-sourcing' initiative, whereby a number of users
10 contribute data over time, allowing refinement of the location database. Results can
11 be improved further by using the received crowd-sourced data to create/refine a map
12 of features of a particular building, so as to model the interference effects and so on.
13 However, it is generally very difficult and inconvenient to have the war-walking/crowd-
14 sourcing done in a structured and rigorous fashion, thus preventing the easy
15 modelling of building features and the like.

16
17 The present invention seeks to address deficiencies in the prior art.

18
19 Summary of the invention

20
21 In a first aspect of the invention, there is provided a method of updating a database of
22 spatial features, said spatial features being associated with a region, and the method
23 comprising: receiving positioning data that has been collected at a plurality of
24 locations within the region; processing the collected positioning data to identify at
25 least one candidate spatial feature (such as a path and/or node) associated with the
26 region; identifying at least one other spatial feature corresponding to said at least one
27 candidate spatial feature, said at least one other spatial feature and said at least one
28 candidate spatial feature as a whole constituting matching spatial features;
29 processing said matching spatial features; and updating the database of spatial
30 features (preferably by updating existing records or creating new entries in the
31 database, as appropriate) in dependence on the processing of said matching spatial
32 features. This provides a way to process (additional) positioning data, such as that
33 received from crowd-sourcing, to update databases of spatial features.

34
35 The positioning data may include at least one of a position estimate and/or
36 measurement data. By measurement data we refer to raw or intermediate data such
37 as may be received by a positioning module and used in the computation of the

position estimate (and as such distinct from the position estimate). Thus in the case of an electromagnetic (EM) signal positioning module, the position estimate may for example include an approximate 2D or 3D position in space, and the measurement data may, for example, include signal identifiers (such as SSID), signal strength measurements, and the like. A pedometer dead reckoning (PDR) positioning system may likewise report an absolute 2D or 3D position, or a relative vector position, and its measurement data may include, for example, accelerometer readings, gyroscope readings, compass measurements and intermediate data such as pacing measurements (which may be deduced from said accelerometer readings and the like). Further types of positioning systems are mentioned below; in these cases measurement data may for example include visual or infrared images (device camera), sound amplitudes, delays and/or waveforms (ultrasound detector), and so on.

The step of identifying at least one other spatial feature may comprise deriving at least one spatial feature from additional positioning data collected within the region. The positioning data may be collected (at least partially) at the same or (at least partially) at a further plurality of locations. The additional positioning data may be received at (or transmitted by) the same device or system as for the positioning data, or by a different device (operated by the same or a different user).

Preferably a correlation algorithm is applied to the spatial features (that is, is applied to the said one or more candidate spatial features and one or more other spatial features including the said at least one other spatial feature) with appropriate inputs. Data relating to the at least one other spatial feature may be received from another system, and/or may be included in 'third party' data that may be purchased by the operator of the present system, or otherwise, for example.

The step of identifying at least one other spatial feature may comprise accessing the database to identify within the database at least one stored spatial feature corresponding to said at least one candidate spatial feature.

The data in the database associated with said at least one stored spatial feature (or any other spatial feature) preferably relates to one or more properties of said at least one stored spatial feature, and is preferably an estimate, such as an estimate of start or end position, length, height, shape, relationship with other spatial features, and so on. A candidate spatial feature may represent an estimate of at least one property of

1 a spatial feature, as above. For example, a candidate node may be an estimate of the
2 location of the node in 2D or 3D space, and a candidate path may be an estimate of
3 the start and end point and may also include intermediate points, curve information,
4 and so on.

5
6 The method may further comprise receiving geographical data relating to a
7 geographical region in the vicinity of the region (or a path taken through the region by
8 a user and/or a mobile user device associated with the user), and wherein identifying
9 at least one other spatial feature comprises deriving (including identifying or
10 generating as appropriate) said at least one other spatial feature from the
11 geographical data.

12
13 The geographical data may in particular include data representing at least one spatial
14 feature. Accordingly, processing said matching spatial features may comprise
15 comparing the position of said at least one candidate spatial feature with the position
16 of said at least one spatial feature.

17
18 The geographical data may also define at least one spatial feature corresponding to
19 an access point of a building (here access point refers to any entrance or exit from
20 the building, and the like, which may be expected to be traversed by a user). In this or
21 in other cases, at least some of said at least one candidate spatial features may be
22 inside a (or the aforementioned) building and the geographical data may define at
23 least one spatial feature outside the building. These features can assist the post-
24 processing of matching spatial features and/or estimated paths within the building so
25 as to relate them to spatial features (such as building access points and features
26 external to the building where positioning can be more accurately carried out) having
27 a more accurate or certain/known location.

28
29 If at least some of said at least one candidate spatial features are inside a building,
30 the geographical data may define at least one spatial feature outside the building, in
31 which case a partial update of the matching spatial features and/or database of
32 spatial features may be carried out. Preferably, however, the geographical data
33 includes spatial or other features inside the building, in appropriate GIS format for
34 example.

35
36 The method may further comprise processing said matching spatial features using
37 the geographical data to validate or adjust said matching spatial features. In this and

1 in any related aspect, processing the matching spatial features may be carried out at
2 any appropriate local, for example at a user handset or on a server which may be a
3 positioning server or computer system connected thereto. In this and any other
4 aspects, this processing may be carried out after the end of a session in which the
5 positioning data is collected (or in other cases at least partly during the session).

6
7 The geographical data may include at least one recorded path (preferably one or
8 more 'ground truth routes', or recorded paths having a relatively high and/or
9 verified/validated accuracy), in which case processing said matching spatial features
10 may comprise validating or adjusting said matching spatial features in dependent on
11 said at least one recorded path (or 'ground truth route'). In this way, the method may
12 further comprise correlating said matching spatial features with at least one position
13 in said at least one recorded path to determine a quality measure associated with
14 said matching spatial features; for example if the estimated position of (one or more)
15 matching spatial features closely match positions on a recorded route then the
16 matching spatial features can be assigned a relatively high quality measure.
17 Additionally or alternatively, the method may further comprise revising (one or more
18 of) said matching spatial features in dependence on said at least one position in said
19 at least one recorded path. Thus a single recorded path can be used to improve the
20 accuracy of the matching spatial features, and/or a number of recorded paths/ground
21 truth routes can be fused, for example subject to passing a threshold quality measure
22 (which may be a quality measure as aforesaid). The estimates can be revised to
23 create spatial features which are best fit to all the considered paths (recorded and
24 recently measured), and so on.

25
26 In any case in which a quality measure is assessed, of individual position estimates
27 and/or partial or whole path elements, if a quality falls below an appropriate threshold
28 an alarm signal may be generated, for example to trigger the removal of apparently
29 incorrect spatial features or to notify map owners/maintainers.

30
31 The method may further comprise processing said matching spatial features to better
32 match the said geographical descriptive data, for example to snap the revised
33 position of (one or more of) the matching spatial features to a pathway, walkway,
34 corridor, room or pavement known from the geographical descriptive (mapping) data.

35
36 The step of processing said matching spatial features preferably further comprises
37 generating at least one composite spatial feature in dependence on said matching

1 spatial features, and updating the database of spatial features includes storing said
2 composite spatial feature in the database. The term 'composite' is not intended to be
3 limiting, and merely denote that the composite spatial feature arises from processing
4 multiple spatial features.

5
6 In a related aspect of the invention, there is provided a method of (automatically)
7 identifying a spatial feature of an indoor region (and/or a method of creating and/or
8 maintaining a spatial features database storing data representing one or more spatial
9 features of an indoor region), the method comprising: collecting (for example, over a
10 navigation session) positioning data relating to an indoor region from a mobile device;
11 identifying one or more candidate spatial features of the indoor region from the
12 collected positioning data; and correlating the said one or more candidate spatial
13 features with one or more other candidate spatial features to determine two or more
14 matching candidate spatial features (that is, candidate spatial features which have
15 been determined to relate to the same spatial feature of the indoor region). The
16 indoor region may for example be one which the mobile device occupies, moves
17 through or towards. The other candidate spatial features may be provided in a local
18 pool of spatial feature data stored on the mobile device or a central pool of spatial
19 feature data stored on one or more servers in data communication with the mobile
20 device). The method preferably further comprises using the matching candidate
21 spatial features to selectively update a spatial features database.

22
23 Preferably the positioning data is received from at least one positioning module (such
24 as a Global Navigation Satellite System, Wi-Fi subsystem, Pedometer Dead
25 Reckoning system, and so on) in a mobile device. Preferably, in particular, said at
26 least one positioning module comprises at least one of: a satellite positioning system
27 module (such as GNSS), a wireless positioning system module (such as a WiFi
28 positioning system) using signals detected from terrestrial electromagnetic signal
29 sources, a pedometer dead reckoning (PDR) positioning system module, and so on.
30 Other possible types of positioning module include: a camera or other imaging
31 device, for example matching captured visible or infrared images with known or
32 estimated geographical features, ultrasound or other sonic systems for ranging and
33 detection of environmental features, time of flight cameras, for obtaining depth
34 information, and so on. The term positioning module may envisage any module,
35 physically located on a user device or otherwise, which is capable of making at least
36 one measurement from which a relative or absolute position may be estimated or
37 inferred.

1
2 The positioning data may be pre-processed (which is to say, subject to an additional
3 processing step) to combine different positioning module data into a single position or
4 other estimate, and so on, for example corresponding to the position estimate as
5 aforesaid. Alternatively the positioning data may be in a 'raw' form as received from
6 the positioning module, corresponding to the measurement data as aforesaid.
7 Preferably the processing steps are carried out partially or wholly on said mobile
8 device, but may be carried out partially or fully remote from the mobile device, for
9 example at a remote server, which may be a location server in a telephone or other
10 network.

11
12 It may be that said matching candidate spatial features are derived from positioning
13 data relating to (e.g. obtained by) one or more mobile devices approaching and/or
14 passing through a spatial feature at different angles and/or from different directions.

15
16 The database of spatial features may include stored positioning data associated with
17 said at least one stored spatial feature, in which case the step of processing said at
18 least one candidate spatial feature and said at least one stored spatial feature
19 includes processing said stored positioning data. The additional information provided
20 by stored positioning data can assist in the estimation of properties of the relevant
21 spatial feature(s). In addition, the method may comprise filtering the stored
22 positioning data to identify anomalous or outdated positioning data, and consequently
23 to identify anomalous or outdated spatial features (for example if the structure of a
24 building is changed), once sufficient additional positioning data is received. In
25 addition, individual elements of the positioning data can retrospectively be identified
26 as unreliable or otherwise excluded from the processing, potentially leading to better
27 results than if only the resulting spatial feature estimations were retained.

28
29 The method may further comprise storing at least a portion of (that is, part of or all of)
30 the collected positioning data in the database of spatial features, preferably by
31 combining it with the (original) stored positioning data. Thus in a subsequent iteration
32 of the method, the collected positioning data (or part thereof) may be used in addition
33 to the original stored positioning data so as to give an improved new estimate of
34 relevant properties of the relevant spatial features.

35
36 Typically a signal measurement profile is associated with each candidate spatial
37 feature. Preferably the signal measurement profile is an electromagnetic signal

1 profile, but may alternatively be a visual or other profile relating to magnetic and other
2 readings, and may for example include images or other visual data/measurements,
3 for example relating to features of the environment imaged as part of the data
4 collection process and/or reference visual features associated with to that location. In
5 one example, the signal measurement profile may include distance or depth readings
6 from ultrasonic or other measurement systems. In particular, the electromagnetic
7 signal profile may include measurements relating to electromagnetic signal sources
8 detected in the vicinity of the spatial feature, such measurements for example relating
9 to signal strength and identifier, and having associated statistical data. Preferably the
10 quality assessment as aforesaid is computed in dependence on the signal
11 measurement profile, and also preferably the signal measurement profile is stored in
12 conjunction with the candidate spatial feature(s), other spatial features or matching
13 spatial features, as appropriate. The signal measurement profile may include data in
14 respect of a plurality of signal or measurement sources, and said sources may be
15 included more than once in the signal measurement profile in some instances. The
16 signal measurement profile may include data relating to a propagation model/path
17 loss model, and the signal sources may include (but are not limited to) Wi-Fi access
18 points, mobile telephone base stations, Bluetooth(RTM) beacons, and other
19 electromagnetic sources.

20
21 Thus the signal measurement profile preferably includes at least one of:
22 electromagnetic signal strength measurements, identifiers associated with
23 electromagnetic signal sources, environmental mapping, distance measurements,
24 image data, acoustic data, data quality assessments, propagation model parameters,
25 and path loss parameters.

26
27 Preferably the aforesaid correlation algorithm (or other algorithm, device or process)
28 carries out the correlation between spatial features in dependence on at least the
29 signal measurement profile as aforesaid.

30
31 The method may further comprise assigning each candidate spatial feature to at least
32 one of a plurality of groups of candidate spatial features.

33
34 Preferably each candidate spatial feature is assigned to a respective one of said
35 groups of candidate spatial features in dependence on its similarity to other candidate
36 spatial features in the same group. The similarity may be determined in terms of

1 determined location or geographical area, similarity of signal measurement profile,
2 similarity of images captured by a device, and so on.

3
4 Each group may correspond to a geographical sub-division of the region, such as a
5 floor, building, office unit, room, corridor, and so on. A candidate feature may typically
6 be added to only one group (though can optionally be added to more than one if
7 appropriate), which can reduce processing requirements. The grouping need only be
8 approximate but usefully corresponds to different areas in a building such as different
9 floors, where locations are naturally segregated, increasing the efficiency of the
10 process.

11
12 Processing the collected positioning data may comprise identifying a plurality of said
13 locations as node locations, and generating node spatial features corresponding to
14 said node locations. Nodes may be key points within an estimated path, such as
15 turning points (locations where a path changes relatively sharply) and floor-changing
16 spatial features (such as stairs, elevators, and so on). The method may further
17 comprise identifying locations intermediate said node locations. In particular,
18 processing the collected positioning data preferably further comprises identifying
19 locations intermediate node locations as path locations, and generating path spatial
20 features corresponding to said path locations. Preferably all path locations
21 intermediate two node locations are transformed into a single path spatial feature.

22
23 The method may further comprise normalising said candidate spatial features based
24 on at least one of: travel time, speed of movement, distance, starting position, end
25 position, a turning point; and a floor change point or region. The parameters may be
26 included in or else derivable from the positioning data (in which case the method may
27 further comprise processing the collected and/or stored positioning data to compute
28 the relevant parameters). Normalisation steps performed prior to correlation may
29 include: rotation and scaling of features; splitting positioning data which relates to
30 relatively long journeys into smaller data portions relating to shorter journeys (for
31 example if a user walks through a floor of a shopping centre, the normalisation
32 algorithm may split the data relating to the entire journey into smaller paths between
33 pairs of nodes prior to correlation); combining positioning data which relates to a
34 plurality of relatively shorter journeys to form a larger data portion relating to a longer
35 journey (for example if a user walks through a plurality of shorter paths in the same
36 floor of a shopping centre, the normalisation algorithm may combine the data relating
37 to the shorter journeys between nodes into a longer path prior to correlation); using

1 the signal measurement profile (or captured images, sonic depth/distance
2 measurements, and so on) to normalise said candidate spatial features, e.g. using
3 the signal profile (or captured images, sonic depth/distance measurements, and so
4 on) to identify shorter paths between nodes from collected data relating to a longer
5 journey. The signal measurement profile (and/or captured images, sonic
6 depth/distance measurements, and so on) may be used to identify common start and
7 end points of paths (e.g. to identify common start and end points of one or more
8 relatively shorter journeys from positioning data relating to longer journeys, or to
9 identify common start and end points of a relatively long journey from positioning data
10 relating to a plurality of shorter journeys).

11
12 It may be that the candidate spatial features input to the correlation algorithm
13 comprise at least one candidate spatial feature from the said smaller data portions
14 relating to shorter journeys (derived by splitting positioning data which relates to
15 relatively long journeys). It may be that the candidate spatial features input to the
16 correlation algorithm comprise at least one candidate spatial feature from a said
17 larger portion relating to a longer journey (derived by combining positioning data
18 which relates to relatively shorter journeys).

19
20 Accordingly, it may be that the method further comprises normalising one or more
21 candidate spatial features by one or more of: rotating a said candidate spatial feature;
22 scaling a said candidate spatial feature; splitting positioning data which relates to
23 relatively long journeys into smaller data portions relating to shorter journeys and
24 deriving one or more candidate spatial features from the said smaller data portions;
25 combining positioning data which relates to a plurality of relatively shorter journeys to
26 form a larger data portion relating to a longer journey and deriving one or more
27 candidate spatial features from the said larger data portion; and normalising a said
28 candidate spatial feature in dependence on a signal measurement profile associated
29 with the said candidate spatial feature.

30
31 Normalisation typically takes into account whether two or more of the said matching
32 candidate spatial features may have been derived from positioning data relating to
33 one or more mobile devices approaching and/or passing through a spatial feature at
34 different angles and/or from different directions.

35
36 The method preferably further comprises generating at least one path estimate in
37 dependence on said at least one candidate spatial feature, and selecting said at least

1 one other spatial feature matching said at least one path estimate. The path estimate
2 is preferably a 'true' path estimate.

3
4 The method may further comprise determining a quality assessment (such as a
5 covariance matrix or other appropriate measure) for a candidate spatial feature (or in
6 particular each path estimate, or node estimate), and processing said matching
7 spatial features in dependence on said quality assessment.

8
9 In more detail, the method may further comprise quality assessing (typically by
10 comparing) one or more (or each of the) possible pairs of candidate spatial features
11 from the said matching candidate spatial features, or quality assessing (typically by
12 comparing) one or more (or each of the) possible pairs of normalised matching
13 candidate spatial features from the said normalised matching candidate spatial
14 features (where provided), to provide one or more quality assessed candidate spatial
15 features (e.g. if candidates of a pair are identical or sufficiently similar it may be that
16 only one quality assessed candidate spatial feature is provided, otherwise typically
17 two quality assessed candidate spatial features are provided per pair), each of the
18 said quality assessed candidate spatial features being associated with one or more
19 quality measures (and typically storing said quality measures and associating the
20 said quality measures with the relevant said quality assessed candidate spatial
21 feature). The method may further comprise: comparing one or more of the said
22 quality assessed candidate spatial features to one or more spatial features from a
23 spatial features database (optionally using the said quality measures associated with
24 the quality assessed candidate spatial features to determine whether the quality
25 assessed candidate spatial features are of greater quality than the spatial features of
26 the spatial features database and, if so, using the said quality assessed candidate
27 spatial feature(s) to update the spatial features database). The method may further
28 comprise combining one or more of the said spatial features from the spatial features
29 database with one or more of the said quality assessed spatial features (e.g. with one
30 or more quality assessed candidate spatial features having one or more quality
31 measures greater than or equal to a corresponding quality measure of the said
32 spatial feature from the spatial features database) to provide a combined spatial
33 feature (e.g. responsive to a determination that the said one or more quality assessed
34 candidate spatial features have one or more quality measures greater than or equal
35 to a corresponding quality measure of the said spatial feature from the spatial
36 features database).

1 A plurality of said at least one candidate spatial features may correspond to a single
2 (real, underlying, or assumed singular) spatial feature. Said plurality may be
3 individual reported readings or data sets relating to said (singular) spatial feature
4 and/or may represent hypotheses of said (singular) spatial feature. The candidate
5 spatial features may as a whole include an entire set of hypotheses relating to a
6 plurality of different real spatial features (in which case the hypotheses may be
7 evaluated per single underlying/assumed spatial feature, or as a whole - for example,
8 per aforesaid group - or in portions thereof). The aforesaid composite spatial feature
9 may for example be a single hypothesis selected from a plurality of hypotheses. For
10 example, the candidate spatial features may include a plurality of candidate node
11 features having different coordinates (amongst other things) representing hypotheses
12 or estimates of the location of a real node traversed by a user, and likewise for path
13 spatial features. Each hypothesis spatial feature is preferably associated with a
14 quality assessment as aforesaid, preferably in the form of a covariance matrix or
15 other appropriate measure.

16
17 Preferably more than one hypothesis is stored in the database or other appropriate
18 storage device, preferably in conjunction with the quality assessment/measure.
19 Accordingly updating the database of spatial features may comprise storing at least
20 one hypothesis of at least one spatial feature (such as a node and the position
21 thereof, and so on). In a process comparable to the grouping of candidate spatial
22 features as aforesaid, the method may further comprise assigning each hypothesis in
23 the database to at least one of a plurality of groups of hypotheses, and each
24 hypothesis may be assigned to a respective one of said groups of hypotheses in
25 dependence on its similarity to other hypotheses in the same group. Similarly, each
26 group may correspond to a geographical sub-division of the region. When the
27 relevant spatial feature is considered at a later time, preferably the hypothesis spatial
28 features are retrieved from the database (for example as the 'other' spatial features
29 compared to a new set of candidate spatial features), and the associated quality
30 assessments can be used to reassess previous estimated positions and other
31 attributes with a minimum of processing power. In one embodiment, some of the
32 hypotheses stored in the database are composite spatial features (for example
33 derived from positioning data gathered by different devices, or derived from
34 positioning data from one or more devices over a particular time period, and so on).

35
36 The method preferably further comprises processing said matching spatial features in
37 the form of a plurality of node spatial features and at least one path spatial feature,

1 and may comprise (as appropriate) transforming stored spatial features into such
2 elements. Processing said matching spatial features preferably comprises identifying
3 matching node spatial features in said matching spatial features, and combining said
4 matching node spatial features into a single node. The method may further comprise
5 adjusting path spatial features in said matching spatial features to conform to the
6 changed node spatial features. The method may comprise grouping similar spatial
7 features first and processing in groups.

8
9 In the case where the database of spatial features includes stored positioning data
10 associated with said at least one other spatial feature, the step of processing said
11 matching features may include processing said stored positioning data. The method
12 preferably further comprises storing at least a portion of the collected positioning data
13 in the database of spatial features.

14
15 The method may further comprise updating the spatial features database by storing
16 the combined spatial feature in the spatial features database (e.g. in place of the said
17 spatial feature of the spatial feature database). In more detail, the method may further
18 comprise storing one or more or all of the said (e.g. matching and/or normalised,
19 where provided and/or quality assessed candidate spatial features having a quality
20 measure exceeding a quality threshold) candidate spatial features in a or the spatial
21 features database.

22
23 It may be that the positioning data collected by the mobile device comprises one or
24 more or each of the following: an estimated (e.g. current) position of the device; a
25 motion vector representing a (current) direction of travel of the device; and a time
26 reference associated with the estimated (current) position and/or the motion vector.
27 Typically the or each motion vector is associated with an or a respective estimated
28 position of the device. Typically the or each motion vector represents a direction of
29 travel of the device at an or a respective estimated position of the device associated
30 with the said motion vector.

31
32 In more detail regarding features mentioned above, the method may comprise
33 dividing one or more or each of the said one or more candidate spatial features
34 and/or one or more of the said matching candidate spatial features and/or one or
35 more of the said normalised matching candidate features and/or one or more of the
36 said quality assessed candidate spatial features into two or more divided (e.g.
37 matching and/or normalised and/or quality assessed as appropriate) candidate

1 spatial features. The method may comprise dividing the said one or more candidate
2 spatial features and/or one or more of the said matching candidate spatial features
3 and/or one or more of the said normalised matching candidate features and/or one or
4 more of the said quality assessed candidate spatial features into two or more nodes
5 (the nodes representing, for example, turning points or floor switching points) and one
6 or more path lines each extending between a respective pair of nodes. The method
7 may comprise: correlating the said nodes to determine one or more matching nodes
8 (e.g. matching nodes which have been determined to relate to the same nodal spatial
9 feature); combining the said matching nodes to provide a combined node; and
10 adjusting the path line(s) extending from the said matching nodes to extend to or from
11 (as appropriate) the said combined node. The method may further comprise:
12 collecting positioning data relating to the said indoor region from the said mobile
13 device in a prior navigation session (e.g. when the said mobile device occupied,
14 passed through or approached the said indoor region); and identifying one or more of
15 the said other candidate spatial features of the indoor region from the positioning data
16 collected in the said prior navigation session.

17
18 Preferably the positioning data is received from at least one positioning module
19 associated with at least one mobile device. Preferably the or each mobile device
20 includes more than one positioning module, but at least one of these may not work
21 indoors (or at least with a predetermined average level of accuracy, and so on). It is
22 preferably processed at least in part on the or each same mobile device. The method
23 may further comprise synchronizing with another device (which may be a server,
24 controller or other centralized element), wholly or in part, at least one of: the collected
25 positioning data, said at least one candidate spatial feature, and said at least one
26 other spatial feature. The method may further comprise accessing the database of
27 spatial features to assist a location service for a mobile device (for example by
28 providing data from the spatial features database to a location server, or alternatively
29 to provide a location service directly based on the same data).

30
31 In more detail, the method may further comprise: collecting positioning data from a
32 second mobile device (e.g. over a navigation session) relating to (e.g. the second
33 mobile device occupying, moving through or towards) the indoor region, the second
34 mobile device being a different mobile device (albeit they may be of the same type)
35 from the said (first) mobile device; and identifying one or more of the said other
36 candidate spatial features of the indoor region from the positioning data collected by
37 the second mobile device.

1
2 In yet more detail regarding the controller mentioned above, the method may further
3 comprise: the mobile user device providing the identified candidate spatial features to
4 the controller (e.g. provided on one or more servers); and the controller correlating
5 the said one or more candidate spatial features with one or more other candidate
6 spatial features from a or the spatial features database to determine two or more
7 matching candidate spatial features (i.e. candidate spatial features which have been
8 determined to relate to the same spatial feature of the indoor region). The method
9 may comprise the controller normalising the said matching candidate spatial features.
10 The method may further comprise the controller quality assessing (typically by
11 comparing) one or more (or each of the) possible pairs of the said matching
12 candidate spatial features to provide one or more quality assessed candidate spatial
13 features, each of the said quality assessed candidate spatial features being
14 associated with one or more quality measures. The method may further comprise the
15 controller combining one or more of the said spatial features from the spatial features
16 database with one or more of the said quality assessed spatial features (e.g. with one
17 or more quality assessed candidate spatial features having one or more quality
18 measures greater than or equal to a corresponding quality measure of the said
19 spatial feature from the spatial features database) to provide a combined spatial
20 feature (e.g. responsive to a determination that the said one or more quality assessed
21 candidate spatial features have one or more quality measures greater than or equal
22 to a corresponding quality measure of the said spatial feature from the spatial
23 features database). The method may further comprise the controller updating the
24 spatial features database by storing the combined spatial feature in the spatial
25 features database (e.g. in place of the said spatial feature of the spatial feature
26 database). The method may further comprise the controller transmitting at least an
27 updated portion of the spatial features database to the mobile device.
28

29 In another aspect of the invention there is provided a data processing system (for
30 example a singular device, a more general data processing apparatus or interlinked
31 apparatus) including (at least one) processor and (at least one) associated memory,
32 said data processing system being operable to update a database of spatial features,
33 said spatial features being associated with a region, and said data processing system
34 being programmed to perform a method of: receiving positioning data that has been
35 collected at a plurality of locations within the region; processing the collected
36 positioning data to identify at least one candidate spatial feature associated with the
37 region; identifying at least one other spatial feature corresponding to said at least one

1 candidate spatial feature, said at least one other spatial feature and said at least one
2 candidate spatial feature as a whole constituting matching spatial features;
3 processing said matching spatial features; and updating the database of spatial
4 features in dependence on the processing of said matching spatial features.

5
6 In a further aspect of the invention there is provided a non-transitory computer
7 readable carrier storing computer program code for causing a data processing
8 system (for example a singular device, a more general data processing apparatus or
9 interlinked apparatus) to update a database of spatial features, said spatial features
10 being associated with a region, said data processing system including (at least one)
11 processor and (at least one) associated memory, and the computer program code,
12 when stored in said memory and executed by said processor, causing said data
13 processing system to perform a method of: receiving positioning data that has been
14 collected at a plurality of locations within the region; processing the collected
15 positioning data to identify at least one candidate spatial feature associated with the
16 region; identifying at least one other spatial feature corresponding to said at least one
17 candidate spatial feature, said at least one other spatial feature and said at least one
18 candidate spatial feature as a whole constituting matching spatial features;
19 processing said matching spatial features; and updating the database of spatial
20 features in dependence on the processing of said matching spatial features.

21
22 The invention may further extend to data processing apparatus (or system)
23 comprising a collection module programmed to collect positioning data from a mobile
24 device (for example over a navigation session) relating to (for example the mobile
25 device occupying, moving through or towards) an indoor region; a spatial feature
26 identification module programmed to identify one or more candidate spatial features
27 of the indoor region from the collected positioning data; and a correlation module
28 programmed to correlate the said one or more candidate spatial features with one or
29 more other candidate spatial features (for example which may be provided in a local
30 pool of spatial feature data stored on the mobile device or a central pool of spatial
31 feature data stored on one or more servers in data communication with the mobile
32 device) to determine two or more matching candidate spatial features (that is,
33 candidate spatial features which have been determined to relate to the same spatial
34 feature of the indoor region).

35
36 In a yet further, related, aspect of the invention, there is provided a method of
37 updating a database of spatial features, said spatial features being associated with a

1 region, and the method comprising: receiving positioning data that has been collected
2 at a plurality of locations within the region; processing the collected positioning data
3 to identify at least one group of candidate spatial features (such as paths and nodes)
4 associated with the region; for each group: accessing the database to identify at least
5 one stored spatial feature corresponding to the respective candidate spatial features
6 in the group, said at least one stored spatial feature and said respective candidate
7 spatial features constituting matching spatial features, processing said matching
8 spatial features, and updating the database of spatial features in dependence on the
9 processing of said matching spatial features. Identifying may comprise selecting or
10 generating, as appropriate.

11
12 The invention may further extend to a method for autonomous indoor spatial features
13 crowd-sourcing comprising the following steps:

- 14 a. Aggregating position data over one navigation session;
- 15 b. Pre-processing the aggregated set of points to generate a rough estimation of
16 spatial features in form of path lines and nodes;
- 17 c. Post processing a group of rough estimations of spatial features to generate
18 multiple true path(s) estimations associated with quality measures;
- 19 d. Comparing the new estimations to the best matches in an existing spatial
20 features database;
- 21 e. Combining existing and new estimations of spatial features to improve the
22 quality of spatial features in the database; and
- 23 f. Updating the database with the combined version and all possible
24 estimations.

25
26 Various aspects of the invention described herein may relate to the detection of
27 estimates of position or characteristics of movement of mobile devices (such as
28 mobile phones) from (typically radio frequency) electromagnetic signals detected
29 from (typically radio frequency) electromagnetic signal sources (e.g. terrestrial
30 electromagnetic signal sources such as Wi-fi access points, Bluetooth(RTM) beacons
31 and the like) using positioning data. Positioning data can be stored as a database of
32 positioning data on a tangible computer readable medium (for example one or more
33 memories). Typical positioning data include identifiers of electromagnetic signals
34 sources (e.g. MAC IDs), and the position (estimated or measured) of electromagnetic
35 signal sources (at least some of which are typically indoors). Databases of positioning
36 data may include the strength of signals from electromagnetic signal sources, or
37 other data from which the strength of signals from the electromagnetic signal sources

1 can be deduced. This positioning data enables mobile user devices to determine
2 their position from the measured strength of signals from electromagnetic signal
3 sources, for example by triangulation. Some databases of positioning data include
4 the strength of signals from electromagnetic signals sources at different locations
5 instead of, or in addition to, the location of the electromagnetic sources. Again, the
6 position of a mobile user device can be determined from the measured strength of
7 signals from electromagnetic signal sources, for example by interpolation.

8
9 The invention, in any aspect, may relate to databases of positioning data for use by
10 mobile user devices to estimate their position more accurately. Further relevant
11 information can be found in US 8,634,359, International Patent Applications
12 WO 2011/077166, WO 2010/052496, WO 2013/041885, WO 2013/054144,
13 WO 2013/041889, WO 2013/108043, WO 2013/171465, WO 2014/006423,
14 WO 2014/016602, WO 2014/091249, US Patent Application 13/923,864 and US
15 provisional Patent Application 62/037,236, each of which is hereby incorporated by
16 reference.

17
18 The invention provides a method for creating a database of geographical spatial
19 features by post processing data submitted by a plurality (e.g. crowd) of users
20 (typically carrying mobile user devices) approaching an indoor area, e.g. from
21 different angles and/or walking in different directions. The method typically involves
22 aggregating inputs from all of the said users to form a pool of geographical spatial
23 features; and processing the pool of geographical spatial features to generate core
24 database entries.

25
26 Another aspect of this invention is to maintain a or the database of geographical
27 spatial features and improve it by post processing further data sourced through the
28 said plurality of mobile user devices. To support this adaptive nature of the
29 geographical spatial feature database, the method also involve a means of splitting,
30 or normalizing, a spatial feature, such as corridor, into multiple simplified spatial
31 features, such as lines and turning points, to support partial correlation with any new
32 data streamed into the pool.

33
34 A further aspect of this invention is to support aggregation of geographical spatial
35 features in a local database versus the centralized database. This involves means of
36 synchronizing local and central databases applying the same steps of normalization
37 and correlation used in maintaining the database.

1
2 The method further extends to data processing apparatus for performing any method
3 aspect of the invention as aforesaid.

4
5 Optional or essential features described above in respect of any one of the various
6 aspects of the invention are at least optional features of any of the aspects of the
7 invention.

8
9 Although various aspects and embodiments of the present invention have been
10 described separately above, any of the aspects and features of the present invention
11 can be used in conjunction with any other aspect, embodiment or feature where
12 appropriate. For example apparatus features may where appropriate be interchanged
13 with method features. References to single entities should, where appropriate, be
14 considered generally applicable to multiple entities and vice versa. Unless otherwise
15 stated herein, no feature described herein should be considered to be incompatible
16 with any other, unless such a combination is clearly and inherently incompatible.
17 Accordingly, it should generally be envisaged that each and every separate feature
18 disclosed in the introduction, description and drawings is combinable in any
19 appropriate way with any other unless (as noted above) explicitly or clearly
20 incompatible.

21 22 Description of the Drawings

23
24 An example embodiment of the present invention will now be illustrated with
25 reference to the following figures in which:

26
27 Figure 1 is a table of typical positioning data;

28
29 Figure 2 is a flowchart of a method of updating a database of spatial features;

30
31 Figure 3 is a flowchart showing the method of Figure 2 in more detail;

32
33 Figure 4 is a flowchart showing the pre-processing step of Figure 3 in more detail;

34
35 Figure 5 is a flowchart of a method of synchronising spatial features updated in
36 accordance with the method of Figure 2;

37

1 Figure 6 is a schematic of a device for use with the method of Figure 2;

2

3 Figure 7 is a schematic of a central controller for use with the method of Figure 5;

4

5 Figure 8 is a schematic of a first embodiment of a system in accordance with the
6 method of Figure 2;

7

8 Figure 9 is a schematic of a second embodiment of a system in accordance with the
9 method of Figure 2;

10

11 Figure 10 is a schematic of a third embodiment of a system in accordance with the
12 method of Figure 2;

13

14 Figures 11a and 11b are example floor plans from a building showing an example
15 navigation path through the building;

16

17 Figures 12a and 12b are a plan view and isometric view of the example navigation
18 path of Figures 11a and 11b;

19

20 Figures 13a and 13b are illustrations of the decomposition of the navigation path of
21 Figures 12a and 12b into different groups of spatial features;

22

23 Figures 14a and 14b are illustrations of the simplification of the groups of Figure 13b
24 into separate spatial features;

25

26 Figure 15 is an illustration of a stored path relating to the building of Figures 11a and
27 11b;

28

29 Figure 16 is an illustration of the simplification of the stored path of Figure 15 into
30 separate spatial features;

31

32 Figures 17a and 17b illustrate the combination of multiple estimated nodes into a
33 single node;

34

35 Figure 18 illustrates a composite path formed by combining nodes according to the
36 process shown in Figures 17a and 17b;

37

Figures 19a and 19b illustrate the decomposition of the composite path of Figure 18 into a minimum number of true paths;

Figures 20a, 20b and 20c illustrate the decomposition of the composite path of Figure 18 into a minimum number of non-overlapping true paths; and

Figures 21a and 21b illustrate the use of electromagnetic signals profiles in an embodiment of the method of Figure 2.

Detailed Description of an Example Embodiment

One real life example of indoor spatial features crowd-sourcing involves a navigation session relating to step by step navigation points followed by a mobile user carrying a smart phone. For every navigation session, the phone would store all coordinates associated with universal time stamps and the correlated motion vector. The motion vector is an estimation of pedestrian movement as distance and bearing from the last coordinates.

The table of Figure 1 provides an example of input data, where

Position type:	represents the method used in obtaining the coordinates;
Universal time:	UTC time in Unix format;
Lat/Lng/alt:	The 3D coordinates defining the location of the phone at this time;
Estimated error:	An indication of possible error in meters;
Floor:	An indication to the floor number in multi-storey building if applicable;
Quality Index:	An indication to the confidence in the data and the quality of the information sources such as GPS, WiFi, Bluetooth(RTM), Accelerometer and digital compass;
Speed:	an estimation of the walking or movement speed in meter per second;
Distance:	An estimation of how many meters the phone moved since last entry; and
Bearing:	An estimation of the phone bearing, movement direction, during this time.

Once the user decides to end the navigation session, the input data mentioned above will be pre-processed and inserted into the pool of spatial features. This initial pre-processing comprises one or more or all of the following steps:

- Split the data into floors and generate one more floor changing spatial feature as a polygon containing consecutive data points with different floor values;
- Streaming each group of floor data into a filter to identify the turning points coordinates as a polygon containing consecutive data points with bearing exceeding the filter threshold; and
- Process every set of data points between (every) consecutive turning points to generate a path line in a form of a line or arc associated with two references to either turning points polygons or floor changing polygons or combination of both.

As a result of processing the input data for one navigation session, a set of spatial features will be added to a local or central pool of spatial features.

The next step comprises post processing all the data in the pool to update the spatial features database. The post processing method comprises one or more or all of the following steps:

- Initial correlation check of all data in pool to group them into multiple matches;
- For each group:
 - o Perform a normalization based on travel time, speed and distance and modify the start point, end point as well as any turning points or floor changing points;
 - o Feed all possibilities into a spatial filter that will output multiple estimations of a true path, each associated with time stamp, statistical measures and uncertainty values;
 - o Fetch from the spatial database all possible matches to the estimated true path;
 - o Break all estimated true path into path lines and nodes (nodes being turning points or floor switching points);
 - o Combine every matching group of nodes into one node and adjust the path lines to follow the combined nodes;
 - o Update the spatial features database with the combined nodes, path lines and the new ones with no matches.

1 If the spatial features database is hosted locally, or shared between limited numbers
2 of mobile devices, the method may also involve a step of synchronizing these data to
3 a central database where it can be shared with larger number of users or mobile
4 devices.

5
6 The synchronization process may comprise one or more or all of the following steps:

- 7
- 8 - Select from the local database all spatial features that have been updated
9 after the last synchronization run;
 - 10 - Send the selected data to the central controller over any means of data
11 transferring;
 - 12 - On receiving the data the controller fetches from the central database all
13 possible matching features;
 - 14 - Run every matching pair into combining filter (same steps as post
15 processing method described above) in respect to the time stamp,
16 statistical measures and uncertainty values;
 - 17 - Update the central database
 - 18 - Send the updates to the local controller to update the local database.
- 19

20 The spatial features may comprise any of the following or any other suitable spatial
21 features: areas (or spaces) within the indoor region (such as rooms or corridors),
22 linear features (e.g. walls), gaps in features (e.g. portals such as doors), floor-change
23 features such as elevators, escalators or staircases, turning points, ends of corridors
24 and so on.

25
26 The methods and systems mentioned above will now be described in more detail,
27 with reference to Figures 2 to 20.

28
29 Figure 2 is a flowchart of a method of updating a database of spatial features
30 according to one embodiment.

31
32 In step S200 positioning data, collected at a plurality of locations, is received. The
33 data may be in the form of the data shown in Figure 1, for example. The positioning
34 data is typically compiled by one or more mobile devices, each having one or more
35 positioning modules including Global Navigation Satellite Systems (GNSS), Wi-Fi
36 rangefinder systems, pedometer dead reckoning (PDR) systems, and so on, though
37 typically the areas of interest are indoors and therefore the available data is a mixture

1 of low accuracy absolute positioning data (for example from the Wi-Fi rangefinding)
2 and low- to high-accuracy relative positioning data (from the PDR systems, for
3 example).

4
5 In Step S202 candidate spatial features are identified, as explained in more detail
6 below (and above). In Step S204, other spatial features (for example from a pool of
7 features or from the same or a further spatial features database) corresponding to the
8 candidate spatial features are identified, both sets of features together constituting
9 'matching spatial features'. The database of spatial features may be a local or remote
10 database, for example used by a positioning service. In step S206, all the matching
11 spatial features are processed, typically to create improved estimates of spatial
12 features, and the spatial features database is updated (S208) as a consequence of
13 the processing, typically by storing (at least) the improved estimates.

14
15 Figure 3 is a flowchart showing the method of Figure 2 in more detail. The flowchart
16 covers the updating of existing features in a spatial features database. However, with
17 appropriate modification (for example to step S308 below, if it refers instead to spatial
18 features within a pool of collected data, rather than to data in an existing spatial
19 features database) a method of creating new entries in the database is described.

20
21 In step S300, positioning data is received as before. In step S302, the positioning
22 data is pre-processed, as will be explained below. While beneficial, this step can be
23 omitted if necessary and/or appropriate.

24
25 In step S304 the positioning data is normalised. The positioning data is adjusted to
26 take into account factors such as travel time, speed and distance, with start point, end
27 points and any relevant turning points and floor-changing points being modified as
28 necessary as a consequence. While beneficial, this step can be omitted if necessary
29 and/or appropriate.

30
31 In step S306, the (if appropriate, pre-processed and normalised) positioning data is
32 processed with a spatial filter to generate multiple estimations of 'true' path. As part of
33 Step S306 (or otherwise), a quality measure (or multiple measures) may be applied
34 to the generated estimates, based for example on the type of positioning and any
35 other relevant factors.

36

1 In step S308, all possible matches to the estimated true path(s) are retrieved from the
2 database of spatial features. The matches may be limited by any appropriate means,
3 for example geographically limited, or limited to a particular number or quality of
4 match. As mentioned above, the described process may be adapted, by search a raw
5 pool of collected spatial features data (rather than an existing spatial features
6 database) to create new data in a spatial features database. Where appropriate,
7 references herein to selecting from a spatial feature database (and/or updating
8 existing data in the database) can be applied alternatively or additionally to selecting
9 from a different (local or other) pool of collected spatial features data (and/or creating
10 new data in the database).

11
12 In step S310 the estimated true path(s), including the candidate true path(s)
13 generated by the spatial filter and the true path(s) retrieved from the database are
14 converted into path lines and nodes. (The processing of the candidate and stored
15 spatial features may as appropriate be divided into separate processing steps at
16 different times.)

17
18 In step S312 matching nodes are grouped into a single node. Nodes which do not
19 match any other may result in new spatial features being generated. In step S314
20 path lines are adjusted to conform to the amended nodes. In step S316, the spatial
21 features database is updated with the combined nodes and updated path lines, any
22 new spatial features arising from the processing in step S314, and (optionally, though
23 usefully) additional positioning data used to create the new estimates, so that
24 subsequent processing steps can take the positioning data into account when
25 creating estimates, and so on.

26
27 Figure 4 is a flowchart showing the pre-processing step of Figure 3 in more detail.

28
29 In step S400, the data is divided into different floors (or other geographical
30 regions/sub-regions, as appropriate, including divisions within the same floor or
31 vertical height). In step S402, floor-changing spatial features are converted into
32 polygons ('floor-changing polygons') containing consecutive data points with different
33 floor values, although other data structures and formats are of course possible.

34
35 In step S404, each group of floor data is processed by a filter (or other appropriate
36 means) to identify turning points, and in step S406 'turning-point polygons' are

1 generated, consisting of polygons containing consecutive data points with bearing
2 exceeding a relevant threshold.

3
4 In step S408 every set of data points between consecutive turning points are
5 processed to generate path lines in the form of a line or arc, and each path line is
6 associated with two references, each reference being either to a turning-point
7 polygon or a floor-changing polygon.

8
9 Thus, the positioning data has been simplified into a floor-changing spatial features,
10 turning-point spatial features, and a series of paths linking them together.

11
12 Figure 5 is a flowchart of a method of synchronising spatial features updated in
13 accordance with the method of Figure 2. This synchronising method relates to a
14 particular embodiment (see below) in which at least one device carries out local
15 processing and storage, and a central controller maintains a central registry of spatial
16 features data, and the two carry out a synchronisation process to ensure that both
17 data stores are up to date. The synchronising method may be executed at any
18 appropriate moment, either on demand by a user, in accordance with a schedule,
19 after a certain amount of data has been updated, acquired or processed, or on
20 request from the central controller, for example.

21
22 In step S500, a local device (having its own local spatial features database) selects
23 from its spatial features database all spatial features which have been updated after
24 the last synchronisation process. In step S502, the device sends the selected data to
25 a central server/controller. In step S504, the central server fetches from its own
26 central spatial features database all possible spatial features matching the spatial
27 features data received from the device. In Step S506, the central server runs every
28 matching pair of spatial features into a combining filter, mirroring the processing
29 carried out at the local device (including steps shown in Figure 3 and described
30 above, for example). The central database is then updated. Because the central
31 server may have received additional data from other devices, or may apply different
32 (for example more sophisticated) processing, the result of the processing may differ
33 from that carried out originally at the device. Accordingly, in step S510, any updated
34 data (with reference to what is known or inferred to be stored at the device, which
35 may for the reasons mentioned above go beyond the data modified in step S508) is
36 sent back to the device. The device then inserts the data received from the central
37 server into its local spatial features database, but in a variant of the present

1 embodiment the local device may as appropriate reprocess the data received from
2 the central server before updating its own database (for example if new data has
3 been received in the meantime).

4
5 Figure 6 is a schematic of a device for use with the method of Figure 2. The device
6 600, which may be a handheld, mobile or other device, contains a processor 602,
7 data storage 604 (which may include the above-mentioned local database of spatial
8 features), (optional) user interface 606, (optional) network (or other communications)
9 interface 608, and one or more positioning modules 610, 612.

10
11 Figure 7 is a schematic of an optional central controller for use with the method of
12 Figure 5. The central controller contains, for example, a processor 702, data storage
13 704 (which may include the above-mentioned central database of spatial features)
14 and network interface 706.

15
16 Figure 8 is a schematic of a first embodiment of a system in accordance with the
17 method of Figure 2. In this embodiment, a single device 800 is provided, with a
18 corresponding database 810 of spatial features.

19
20 Figure 9 is a schematic of a second embodiment of a system in accordance with the
21 method of Figure 2. In this embodiment, a central server/controller 910 has an
22 associated database of spatial features 912, connected to a plurality of devices 930,
23 932, 934 via a network 920 or other communications link. The devices are typically
24 autonomous (for example handheld devices such as smartphones) but do not contain
25 a local spatial features database (though they may have local caches of various
26 sorts). In one mode of operation, the devices 930, 932, 934 used the server 910 as a
27 database server, carrying out spatial features processing locally but using the server
28 database 912 as a repository of the data. In another mode of operation, the
29 processing is carried out partly or wholly at the server 910, which receives positioning
30 data from the devices 930, 932, 934 and transmits back further positioning data, such
31 as an estimated current position of the relevant device, for example.

32
33 Figure 10 is a schematic of a third embodiment of a system in accordance with the
34 method of Figure 2. In this embodiment, a central server 1010 as before is associated
35 with a central repository (database) 1012 of spatial features, and in communication
36 with a plurality of devices 1030, 1032, 1034 via a network (or other communications
37 link) 1020. In this embodiment, however, each device 1030, 1032, 1034 is associated

1 with its own local database 1040, 1042, 1044 of spatial features. A method identical
2 to, or similar to, that described above in relation to Figure 5 is used to synchronise
3 data across all the databases 1012, 1040, 1042, 1044. Other arrangements, for
4 example incorporating a mix of the system of Figures 9 and 10, are of course
5 possible.

6
7 A worked example, representing a simplified and abstracted version of a real life
8 example for the sake of ease of explanation, will now be described with reference to
9 Figures 11 to 20.

10
11 Figures 11a and 11b are example floor plans from a building showing an example
12 navigation path through the building, as might be taken by a user of a mobile device
13 corresponding for example to the device of Figure 6 in any one of the systems as
14 shown in Figures 8 to 10. A lower floor 1100 and a higher floor 1102 are shown,
15 connected by elevators 1120 and a stairwell 1122. The present example relates to
16 consecutive floors, but the same principles may apply, for example, to a journey
17 taken from one floor to another floor several storeys above or below (for example by
18 elevator), or to a journey within one floor or many floors, or in areas limited
19 geographically in other ways (for example in different buildings on the same or on
20 different levels), or wholly or partially outdoors, and so on. The path taken 1110 is
21 shown as a dashed line overlaid on the floor plans, which omit details of offices and
22 so on for simplicity, and is broken in the region of the stairwell 1122, which (like the
23 elevator 1120) constitutes a floor-changing zone as described above. Data (or
24 sampling) points, corresponding to locations where positioning data is collected from
25 at least one positioning module associated with the device, are shown with small
26 solid circles 1112. For ease of illustration, the 'true path' taken by a user of the device
27 is shown. In a real life example, there may be more or fewer data points 1112, and
28 the accuracy will typically be lower, especially indoors where a satellite signal is not
29 available for use with GNSS systems. Examples of these inaccuracies, and systems
30 for compensating for them and providing appropriate estimates and quality indices
31 are given in the co-pending applications referred to above.

32
33 Figures 12a and 12b are a plan view and isometric view of the example navigation
34 path of Figures 11a and 11b. Here the unbroken (true) navigation path 1200 is
35 shown, as well as planes 1210, 1212 representing the two different floors. The
36 landings of the stairwell area are also shown for ease of interpretation.

Figures 13a and 13b are illustrations of the decomposition of the navigation path of Figures 12a and 12b into different groups of spatial features. Figure 13a shows a region 1302 of the navigation path 1300 which is assessed (from prior processing and/or by consideration of the positioning data, e.g. the height) as relating to a floor-changing spatial feature. The navigation path is decomposed into two groups 1310, 1320 corresponding to navigation paths 1312, 1322 within two different floors. The portion of the navigation path relating to the floor-changing spatial feature is simplified, as described above, into a polygon 1332 having one data point per floor. The path 1312 corresponds to the navigation path taken on the lower floor, and the path 1322 corresponds to the navigation path taken on the upper floor.

Figures 14a and 14b are illustrations of the simplification of the groups of Figure 13b into separate 'candidate' (C) spatial features. Here, the two paths 1312, 1322 of Figure 13b are divided into nodes and 'simple' paths C_1 to C_{11} , which are shown in exploded form for ease of explanation. The path 1312 on the lower floor is decomposed into path C_1 , C_2 and a variety of paths C_3 , C_4 , C_5 and C_5'' corresponding to different true path estimations 1400 of the same element of the path 1312. In more detail, the true path estimates 1400 include one solution C_3 with two nodes joined by one arcing path (passing through the data point shown with a dashed line, which has been eliminated as part of the process), one solution C_4 with two nodes joined by one straight path, and a further solution C_5 , C_5'' with three nodes (corresponding essentially to the original data points) and two straight paths inbetween. Each of the solutions C_3 , C_4 , C_5 , C_5'' is attributed a quality measure indicating the quality of the estimate. In a real world example there may be more solutions outputted than as shown in Figures 14a and 14b; the set of solutions 1400 are merely indicative.

The navigation path 1322 from Figure 13b of the upper floor is decomposed in this example more simply into elements C_6 , C_7 , C_8 , C_9 , C_{10} , C_{11} , again shown in exploded form in Figure 14b for ease of illustration. The nodes shown at intersection 1402 will be discussed further below by way of an example of the processing method described above. In Figure 14b, various data points have been eliminated because they failed to meet the threshold for a turning point, for example because the change in bearing was below a threshold (or, put another way, the angle subtended at the intersection did not fall sufficiently below 180 degrees to be considered to represent a substantial change in direction).

1 As a result of the processing illustrated in Figures 13 and 14, it will be appreciated
2 that the number of data points has been reduced, and the structure of the spatial
3 features greatly simplified.

4
5 Figure 15 is an illustration of a stored path relating to the building of Figures 11a and
6 11b, and in particular relating to the lower floor and navigation path 1322 of Figure
7 13b. The path is a model (M) of spatial features, and may be stored and/or defined in
8 any appropriate way. In this example the model M defines a particular path through
9 the floor in question. The deviation of the navigated path 1322 from the model path M
10 is illustrated with a dotted line.

11
12 Figure 16 is an illustration of the simplification of the stored path of Figure 15 into
13 separate spatial features M_1 to M_7 . The process corresponds essentially to that
14 undertaken in Figures 14a and 14b. As a result of the process, the model path M is
15 simplified into simple nodes and paths, for ease of comparison with and joint
16 processing with the candidate spatial features in Figures 14a and 14b. In one
17 embodiment, spatial features are stored in the database in the form shown in Figure
18 16, obviating the need for the present step of processing. The nodes shown at 1600
19 coincide approximately (geographically) to the nodes shown at 1402 in Figure 14b.

20
21 Figures 17a and 17b illustrate the combination of multiple estimated nodes into a
22 single node N. When the data derived from the model path M is combined with the
23 data derived from the navigation path (in accordance with the method described
24 above), the paths C_{10} , C_{11} , M_5 , M_6 meet approximately within the area 1700
25 corresponding to the areas 1402 and 1600 above. As part of the node combining
26 process mentioned earlier, the estimates for the four nodes are combined to form a
27 single node N. The weighting/quality indices associated with the four nodes are taken
28 into account, so that the node N is not necessarily at the geographical centre of the
29 pre-combined nodes. After the node combination, paths are adjusted to conform to
30 the adjusted node positions and the data is simplified. Figure 17b shows pre-existing
31 path elements M_5 , M_6 and a new path element M_8 derived from the (new) positioning
32 data.

33
34 Figure 18 illustrates a composite path formed by combining nodes according to the
35 process shown in Figures 17a and 17b. This shows the effect of combining the path
36 elements M_1 to M_8 resulting from the node combining and re-pathing process

mentioned above. The path elements will normally need to be further processed in an appropriate fashion in order to update the database of spatial features.

Figures 19a and 19b illustrate the decomposition of the composite path of Figure 18 into a minimum number of true paths. Here, paths M_A and M_B represent all possible traversals of the composite path in Figure 18.

Figures 20a, 20b and 20c illustrate the decomposition of the composite path of Figure 18 into a minimum number of non-overlapping true paths. Here, paths M_A , M_B and M_C can be reassembled to form the composite path in Figure 18. This form of spatial features can have benefits for path-finding, for example, but any appropriate storage format can be used.

Figures 21a and 21b illustrate the use of electromagnetic signal profiles in an embodiment of the method of Figure 2.

In this embodiment (as also in embodiments described above) the spatial features processing system detects sudden changes in GPS quality metrics to flag an entrance (or exit) and any major change in heading.

Away from entrances and exits, typically the positioning data received from different mobile devices following a particular path between two nodes (or the same device retracing the same route) is not identical, for example if two or more mobile devices collecting PDR (pedometer dead reckoning) positioning data are oriented differently from each other (if they were in a pocket, in a hand, in a calling position, and so on). In these cases, the direction reported by the compass (and therefore the estimated positions along the path or at the nodes) will look very different in each case. Due to these differences in the collected positioning data, positioning data which relates to the same spatial feature (such as a node or a path) may not be correctly correlated (that is, the correlation algorithm may not in the first instance correctly determine that the positioning data relates to the same spatial feature).

To assist with this problem, an electromagnetic signal profile (for example, relating to Bluetooth(RTM) and/or Wifi signals received by the mobile device as it follows the path in question) can be generated in respect of each candidate spatial feature which is taken into account during the correlation stage (that is, the stage which identifies matching spatial features). Thus, even when the positioning data is not sufficiently

similar for the correlation algorithm to identify that it relates to the same spatial feature, the electromagnetic signal profile will provide a secondary indicator which the algorithm can use to determine that the positioning data does indeed relate to the same spatial feature. This can also prevent the identification of false nodes and paths. Ordinarily, the electromagnetic signal profile cannot be used without the positioning data to identify spatial features.

By way of example, Figure 21a shows an interior space 2100 and a simplified version of the (actual) path 2102 taken through the space by a user participating in the data collection, and the (actual) nodes 2104, 2106, 2108, 2110 through which the simplified path passes, from entry point 2104 to exit point 2110.

As mentioned above, when the received data is processed, each of the reported points (nodes) 2104, 2106, 2108, 2110 is associated with an electromagnetic signals profile and may possibly include other profiles such as magnetic field measure. These profiles are then used for matching all submissions from different users to the same group, if they belong to the same node. One example of an electromagnetic signals profile could be represented as a fingerprint array such as:

$$\{ (BSSID, \mu_{RSSi}, \sigma_{RSSi}), \dots \}$$

where $BSSID$ is the identifier of the signal source, μ_{RSSi} is the median of $RSSi$ (received signal strength) values for all submissions that matches this node, and σ_{RSSi} is the standard deviation of $RSSi$ values for all submissions that matches this node.

On the other hand, all position data recorded between two nodes are used to create a path line (the individual portions of line 2102) defined by travel distance and covariance matrix indicating if any transformation had to be made in order to fit the path line between nodes. Similar to the nodes each path line would also hold radio profile and other profiles. An example of path line radio profile is explained below:

$$\{ (BSSID, (X,Y), \mu_{RSSi}, \sigma_{RSSi}, RSS0, N), \dots \}$$

where x/y are coordinates of the central propagation point on the path line, usually the point with strongest $RSSi$; and μ_{RSSi} and σ_{RSSi} are the statistical values for the central propagation point signal strength. This is required when combining multiple submissions or when there is a range of strong signals in one submission. $RSS0$ and

1 N are the propagation parameters for a particular path loss model (which describes
2 the propagation between the signal source and the path). Different propagation
3 parameters may be specified for either side of the central propagation point on the
4 path (for example first propagation parameters may be specified for where the path
5 extends between first and second nodes, and second propagation parameters for
6 between the central propagation point and the second node).

7
8 The profile should have multiple entries for all signal sources which were visible
9 throughout the transit on the relevant path line and might have duplicates if the same
10 WAP was seen in two segregated regions of the same path. The signal profile for a
11 path may have duplicated entries for a particular signal source if, for example, that
12 signal source was visible with a first set of parameters over a first portion of the path,
13 visible with a second set of parameters over a second portion of path, and invisible to
14 the mobile device over a third portion of the path. The electromagnetic signal profiles
15 may take any other suitable form.

16
17 As a crowd based solution, each spatial feature would typically have many
18 submissions that will either agree or disagree on certain parameters including
19 location. Therefore, each feature is associated with a quality measure or covariance
20 matrix (see for example the matrix-algebra/covariance-matrix.aspx page at
21 stattrek.com) describing the variance between different submissions of all
22 parameters. An example of such parameters is shown below:

23
24 Node (turning point): {Number of valid submissions, Average location error, Average
25 compass error, Distance from entrance, Accuracy}

26
27 This matrix is created for each group of submissions sharing a similar radio profile,
28 such as 80% matching WAPs and signal strength. Then the matrix is used to cluster
29 such submissions into multiple hypotheses, mainly based on distance but optionally
30 based on any combination of thresholds. A probability is then assigned to each one.
31 Finally the overall data can be plotted as in Figure 21b, showing multiple hypothesis
32 (unfilled circles) surrounding the favoured hypothesis or actual values (filled circles)
33 in respect of a single path element (shown in dotted line).

34
35 Multiple hypotheses are kept in the database to ensure a smoother switch if further
36 submissions have boosted the probability for any of them. A range of candidates may
37 be selected and tested to determine whether they are over a certain probability

1 threshold, to try and fit combination of multiple features together, such as path lines
2 and nodes. A selected node may be validated against neighbouring path lines, and
3 vice versa.

4
5 Typically the correlation stage is performed on a server, but may alternatively be
6 performed by the mobile device or by a device intermediate the mobile device and
7 the server. The types of electromagnetic signal sources being used are typically
8 terrestrial radio-frequency electromagnetic signal sources, such as (but not limited to)
9 Bluetooth(RTM) beacons, Wi-Fi access points and 5G (or other) short range mobile
10 towers and/or transceivers (sometimes referred to as 'nanocells' or 'microcells').

11
12 With regard to any of the foregoing embodiments and variants, spatial features may
13 be nested and/or abstracted, such that a floor/storey may be considered a single
14 spatial feature, containing within it sub-features such as portals, corridors, and so on.
15 The spatial features database may include or be associated with a database of
16 electromagnetic signal sources (such as wireless access points, Bluetooth(RTM)
17 beacons, mobile phone base stations, and so on) available in the vicinity of the region
18 being modelled, so as to assist in the provision of a mobile device location service.

19
20 It will be appreciated that the method described above is also applicable to outdoor
21 regions. Spatial features outdoors may for example include paths, roads, bridges,
22 crossing points, building entrances, and so on. Navigation sessions may partly or
23 wholly extend into outdoor regions. Part of a pre- or post-processing step may include
24 dividing a navigation session into indoor and outdoor portions, for example based on
25 positional data received at a relevant device (for example a poor performance of
26 satellite-based positioning modules, a detection of light levels, or comparison of
27 estimated location with geographical data, and so on). The pre-processing may for
28 example eliminate outdoor portions so as to selectively process only the indoor
29 portions.

30
31 Although the present invention has been described above with reference to specific
32 embodiments, it will be apparent to a skilled person in the art that modifications lie
33 within the spirit and scope of the present invention.

34

35

1 Claims

2
3 1. A method of updating a database of spatial features, said spatial features
4 being associated with a region, and the method comprising:

5 receiving positioning data that has been collected at a plurality of locations
6 within the region;

7 processing the collected positioning data to identify at least one candidate
8 spatial feature associated with the region;

9 identifying at least one other spatial feature corresponding to said at least one
10 candidate spatial feature, said at least one other spatial feature and said at least one
11 candidate spatial feature as a whole constituting matching spatial features;

12 processing said matching spatial features; and

13 updating the database of spatial features in dependence on the processing of
14 said matching spatial features.

15
16 2. A method according to Claim 1, wherein identifying at least one other spatial
17 feature comprises deriving at least one spatial feature from additional positioning
18 data collected within the region.

19
20 3. A method according to Claim 1, wherein identifying at least one other spatial
21 feature comprises accessing the database to identify within the database at least one
22 stored spatial feature corresponding to said at least one candidate spatial feature.

23
24 4. A method according to Claim 1, further comprising receiving geographical
25 data relating to a geographical region in the vicinity of the region, and wherein
26 identifying at least one other spatial feature comprises deriving said at least one other
27 spatial feature from the geographical data.

28
29 5. A method according to Claim 4, wherein processing said matching spatial
30 features comprises comparing the position of said at least one candidate spatial
31 feature with the position of said at least one spatial feature.

32
33 6. A method according to Claim 4, wherein the geographical data defines at
34 least one spatial feature corresponding to an access point of a building.

35

1 7. A method according to Claim 4, wherein at least some of said at least one
2 candidate spatial features are inside a building and the geographical data defines at
3 least one spatial feature outside the building.

4
5 8. A method according to Claim 4, wherein processing said matching spatial
6 features comprises using the geographical data to validate or adjust said matching
7 spatial features.

8
9 9. A method according to Claim 4, wherein the geographical data includes at
10 least one recorded path, and processing said matching spatial features comprises
11 validating or adjusting said matching spatial features in dependence on said at least
12 one recorded path.

13
14 10. A method according to Claim 9, further comprising correlating said matching
15 spatial features with at least one position in said at least one recorded path to
16 determine a quality measure associated with said matching spatial features.

17
18 11. A method according to Claim 10, further comprising revising said matching
19 spatial features in dependence on said at least one position in said at least one
20 recorded path.

21
22 12. A method according to Claim 1, wherein processing said matching spatial
23 features further comprises generating at least one composite spatial feature in
24 dependence on said matching spatial features, and updating the database of spatial
25 features includes storing said composite spatial feature in the database.

26
27 13. A method according to Claim 1, further comprising assigning each candidate
28 spatial feature to at least one of a plurality of groups of candidate spatial features.

29
30 14. A method according to Claim 13, wherein each candidate spatial feature is
31 assigned to a respective one of said groups of candidate spatial features in
32 dependence on its similarity to other candidate spatial features in the same group.

33
34 15. A method according to Claim 13, wherein each group corresponds to a
35 geographical sub-division of the region.

36

1 16. A method according to Claim 1, wherein processing the collected positioning
2 data comprises identifying a plurality of said locations as node locations, and
3 generating node spatial features corresponding to said node locations.
4

5 17. A method according to Claim 16, wherein processing the collected positioning
6 data further comprises identifying locations intermediate node locations as path
7 locations, and generating path spatial features corresponding to said path locations.
8

9 18. A method according to Claim 17, wherein all path locations intermediate two
10 node locations are transformed into a single path spatial feature.
11

12 19. A method according to Claim 1, further comprising normalizing the candidate
13 spatial features based on at least one of: travel time, speed of movement, distance,
14 starting position, end position, a turning point; and a floor change point or region.
15

16 20. A method according to claim 1, further comprising normalising one or more
17 candidate spatial features by one or more of: rotating a said candidate spatial feature;
18 scaling a said candidate spatial feature; splitting positioning data which relates to
19 relatively long journeys into smaller data portions relating to shorter journeys and
20 deriving one or more candidate spatial features from the said smaller data portions;
21 combining positioning data which relates to a plurality of relatively shorter journeys to
22 form a larger data portion relating to a longer journey and deriving one or more
23 candidate spatial features from the said larger data portion; and normalising a said
24 candidate spatial feature in dependence on a signal measurement profile associated
25 with the said candidate spatial feature.
26

27 21. A method according to Claim 13, wherein the method further comprises
28 generating at least one path estimate in dependence on said at least one candidate
29 spatial feature, and selecting said at least one other spatial feature matching said at
30 least one path estimate.
31

32 22. A method according to Claim 1, further comprising determining a quality
33 assessment for each candidate spatial feature, and processing said matching spatial
34 features in dependence on said quality assessment.
35

36 23. A method according to Claim 1, wherein a plurality of said at least one
37 candidate spatial features correspond to a single spatial feature.

1
2 24. A method according to Claim 1, wherein updating the database of spatial
3 features comprises storing at least one hypothesis of at least one spatial feature.

4
5 25. A method according to Claim 24, further comprising assigning each
6 hypothesis in the database to at least one of a plurality of groups of hypotheses.

7
8 26. A method according to Claim 25, wherein each hypothesis is assigned to a
9 respective one of said groups of hypotheses in dependence on its similarity to other
10 hypotheses in the same group.

11
12 27. A method according to Claim 25, wherein each group corresponds to a
13 geographical sub-division of the region.

14
15 28. A method according to Claim 1, wherein a signal measurement profile is
16 associated with each candidate spatial feature.

17
18 29. A method according to Claim 28, wherein the signal measurement profile
19 includes at least one of: electromagnetic signal strength measurements, identifiers
20 associated with electromagnetic signal sources, environmental mapping, distance
21 measurements, image data, acoustic data, data quality assessments, propagation
22 model parameters, and path loss parameters.

23
24 30. A method according to Claim 13, wherein the method further comprises
25 processing said matching spatial features in the form of a plurality of node spatial
26 features and at least one path spatial feature.

27
28 31. A method according to Claim 30, wherein processing said matching spatial
29 features comprises identifying matching node spatial features in said matching spatial
30 features, and combining said matching node spatial features into a single node.

31
32 32. A method according to Claim 31, further comprising adjusting path spatial
33 features in said matching spatial features to conform to the changed node spatial
34 features.

35
36 33. A method according to Claim 1, wherein the database of spatial features
37 includes stored positioning data associated with said at least one other spatial

1 feature, and processing said matching features includes processing said stored
2 positioning data.

3
4 34. A method according to Claim 33, further comprising storing at least a portion
5 of the collected positioning data in the database of spatial features.

6
7 35. A method according to Claim 1, wherein the positioning data is received from
8 at least one positioning module associated with at least one mobile device.

9
10 36. A method according to Claim 1, further comprising synchronizing with another
11 device, wholly or in part, at least one of: the collected positioning data, said at least
12 one candidate spatial feature, and said at least one other spatial feature.

13
14 37. A method according to Claim 1, further comprising accessing the database of
15 spatial features to assist a location service for a mobile device.

16
17 38. A data processing system including a processor and associated memory, said
18 data processing system being operable to update a database of spatial features, said
19 spatial features being associated with a region, and said data processing system
20 being programmed to perform a method of:

21 receiving positioning data that has been collected at a plurality of locations
22 within the region;

23 processing the collected positioning data to identify at least one candidate
24 spatial feature associated with the region;

25 identifying at least one other spatial feature corresponding to said at least one
26 candidate spatial feature, said at least one other spatial feature and said at least one
27 candidate spatial feature as a whole constituting matching spatial features;

28 processing said matching spatial features; and

29 updating the database of spatial features in dependence on the processing of
30 said matching spatial features.

31
32 39. A non-transitory computer readable carrier storing computer program code for
33 causing a data processing system to update a database of spatial features, said
34 spatial features being associated with a region, said data processing system
35 including a processor and associated memory, and the computer program code,
36 when stored in said memory and executed by said processor, causing said data
37 processing system to perform a method of:

1 receiving positioning data that has been collected at a plurality of locations
2 within the region;

3 processing the collected positioning data to identify at least one candidate
4 spatial feature associated with the region;

5 identifying at least one other spatial feature corresponding to said at least one
6 candidate spatial feature, said at least one other spatial feature and said at least one
7 candidate spatial feature as a whole constituting matching spatial features;

8 processing said matching spatial features; and

9 updating the database of spatial features in dependence on the processing of
10 said matching spatial features.

INTERNATIONAL SEARCH REPORT

International application No
PCT/GB2015/052798

A. CLASSIFICATION OF SUBJECT MATTER
INV. G01C21/20 G01C21/32
ADD.

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
G01C

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

EPO-Internal, WPI Data

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	US 8 386 422 B1 (KADOUS MOHAMMED WALEED [US] ET AL) 26 February 2013 (2013-02-26)	1-3, 33-35, 37-39
Y	abstract figures 1-13C column 1, line 46 - line 48 column 2, lines 12-13 column 7, line 51 - column 8, line 8 column 8, line 38 - line 52 column 13, line 64 - line 64 column 14, lines 6, 17-48 column 15, lines 43-45 claims 1-23 ----- -/--	4-9

Further documents are listed in the continuation of Box C.

See patent family annex.

* Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

Date of the actual completion of the international search

18 January 2016

INTERNATIONAL SEARCH REPORT

International application No.
PCT/GB2015/052798

Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fees, this Authority did not invite payment of additional fees.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1-11, 33-35, 37-39

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.
- ☐ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.
- ☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. claims: 1-11, 33-35, 37-39

Identifying at least one other spatial feature

2. claims: 12, 22

Processing matching spatial features

3. claims: 13-15, 19-21, 23, 28-32

Processing candidate spatial features

4. claims: 16-18

Processing collected positioning data

5. claims: 24-27

Updating database

6. claim: 36

Synchronizing with another device
