5 It is known that higher plants have a general plant defense mechanism
against plant pathogens. At the present, the mechanism that triggers the activa-
tion of plant defense mechanisms and induces systemic resistance is not known.
10 It is known that pathogenic attack can cause in plants the synthesis of high
levels of Pathogenesis-Related (PR) proteins. Among these, PR-1 is usually
15 synthesized in response to viral attack; PR-2 encodes a β -1,3-glucanase, which
may serve as an anti-bacterial/fungal enzyme; PR-3 encodes an anti-fungal
enzyme, chitinase (Linthorst, 1991); Phenylalanine ammonia-lyase (PAL), a
20 key enzyme in the phenylpropanoid pathway that is involved in the biosyn-
thesis of phenolic compounds (Bowles, 1990).

 Transgenic plants of this invention contain much higher levels of PR
25 proteins and salicylic acid (SA) than corresponding wild-type plants, and
accumulate UV-fluorescence compounds (accumulation of UV fluorescence
compounds is a well documented anti-microbial process that is part of the plant
30 defense mechanism). Higher endogenous levels of SA are known to function as
a signal for systemic acquired resistance against a broad spectrum of pathogens
(including virus, bacteria and fungi) in plants. Upon challenge with viral and
35 bacterial pathogens, it has been found that the transgenic plants provided by
this invention show heightened disease resistance, similar to systemic acquired
40 resistance.

 The following is a list of designations used herein and the designations
have the following definitions:

45 bO gene - bacterio-opsin gene

 Cab-t - chlorophyll a/b binding protein transit peptide

 GUS - β -glucuronidase coding region

50 HR - Hypersensitive Response

- 5 NOS - nopaline synthase gene
Ω - synthetic omega translation enhancing sequence
PCR - polymerase chain reaction
10 PR - Pathogenesis Related Proteins, for example, PR-1, PR-2 and PR-3
SA - salicylic acid
15 SAR -systemic acquired resistance
TMV - tobacco mosaic virus
TNV - tobacco necrosis virus
20 WT - wild-type plants (plants which are not transgenic)

SUMMARY OF THE INVENTION

25 Provided by this invention is a process to provide higher plants with enhanced resistance to pathogenic attack by one or more plant pathogens by transforming cells of higher plants with the bO gene. The bO gene is present in
30 the bacteria *Halobacterium halobium*. The plants can be transformed using various means including using vectors, such as binary vectors, as illustrated in
35 FIG. 1.

40 Provided also are higher plant cells transformed to encode the bO gene, resulting in enhanced resistance to the pathogenic attack by one or more plant pathogens.

45 Also, provided are transgenic higher plants which encode the bO gene resulting in higher plants having enhanced resistance to pathogenic attack by one or more plant pathogens.

50 Provided also are bO vectors which can be used to transform the cells of higher plants according to the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 are diagrams showing: (1) the binary vector EL-301 having a bO gene segment, a 35S segment which is a promoter fragment (800 base), an "Ω" segment which is the omega translation enhancing segment sequence, and a Cab-t segment which represents Cab-transit peptide; (2) the RM-102 vector which corresponds to the EL-301 vector except it does not have the Cab-transient peptide segment; transgenic plants transformed using these vectors form spontaneous lesions (lesion mimic); (3) RM 101 vector corresponding to EL-301 vector except the bO segment of EL-301 has been replaced with the GUS (β-glucuronidase) coding region, RM-101 is a control vector (this vector when used to transform plants was found to provide plants indistinguishable from control SR-1 plants); and (4) EL-RM-XX vectors for pathogen driven hypersensitive response in transgenic plants; the pathogen-responsive promoter (PRP segment) will cause localized pathogen derived high expression of the bO gene, resulting in the formation of lesions (much like the spontaneous lesions formed on transgenic plants that express high levels of the bO gene).

35

FIG. 2A shows the structure of EL binary vector.

40

FIG. 2B shows screening of transgenic tobacco plants that express the bO gene using RNA gel blot analysis with a probe to the bO gene (top panel) and with a probe to the 18S ribosomal RNA (bottom panel, as control).

45

FIG. 3A shows a leaf of a lesion mimic phenotype of a high expressor demonstrating the appearance of spontaneous lesions on a tobacco plant leaf.

FIG. 3B shows a leaf of a lesion mimic phenotype of a high expressor demonstrating the appearance of spontaneous lesions on a tobacco plant stem.

50

FIG. 4 is a bar graph having lanes 1-4 showing SA levels in leaves of control wild-type (WT) and transgenic (EL301) plants expressing the bO gene.

5 Plant material was collected from upper (no lesions) and lower (with lesions)
leaves of 5-week-old bO expressing plants and wild-type plants. Leaf tissue
10 (0.3 g) was analyzed for total SA content as described in Methods section
appearing below. The data presented are the mean and standard deviation of
five individual samples gFW, grams fresh weight, of tissue.

15 FIG. 5 shows expression of genes encoding PR proteins and phenyl-
alanine ammonia-lyase (PAL) in transgenic tobacco plants expressing the bO
gene. Expression of PR proteins and PAL was compared between various
20 leaves of a greenhouse grown wild-type plant (WT, 1 to 8, top to bottom) and a
transgenic tobacco plant expressing the bO gene (EL 301A, 1 to 9, top to bot-
tom). Occurrence of spontaneous lesions is indicated (+) on the bottom leaves
25 of the bO-expressing transgenic plant. Leaves obtained from top (leaf number
1) to bottom (leaf number 8 or 9) of a wild-type (WT) and a transgenic (RI
progeny of EL 301) Samsun NN greenhouse-grown plants were analyzed by
30 RNA gel blots and immunoblots. Total RNA (30 μ g) was loaded in each lane,
and hybridization was conducted with the probes indicated at left. PR-1, PR-2
and PR-3 transcripts were detected with the corresponding tobacco cDNAs as
35 probes and the level of PAL transcript with a corresponding parsley cDNA as a
probe. PR-1 protein was detected via immuno-blot with a monoclonal anti-PR-
40 1 antibody.

45 FIG. 6 is a protein gel analysis showing occurrence of PR proteins in the
intercellular fluid of leaf tissue with spontaneous lesions (EL 301, with lesions)
or without lesions (EL 301, no lesions) from bO-expressing plants. The level
of PR proteins is compared with the intercellular fluid from mock infected (WT
50 mock) and TMV infected (WT TMV) wild-type Samsun NN plants. Intercellu-
lar fluid was collected and analyzed according to Lawton et al. (1993), The

5 molecular biology of systemic acquired resistance. In Mechanisms of Plant
Defence Responses, B. Fritig and M. Legrand, eds (Dordrecht, Netherlands,
Kluwer Academic Publishers), pp. 422-432.

10 FIG. 7 shows the accumulation of UV-fluorescence compounds in
leaves of an EL-301 transgenic plant:

- 15 7A - Control WT leaf
7B - The same WT leaf showing no occurrence of UV-fluorescence
compounds
20 7C - Transgenic EL-301 leaf with spontaneous lesions
7D - The same EL-301 leaf showing accumulation of UV-fluores-
cence.

25 FIG. 8 are photographs of leaves of tobacco plants showing heightened
disease resistance of transgenic plants expressing bO to TMV and TNV infec-
tion:

- 30 8A (a) Control WT tobacco infected with TMV
8B (b) Equivalent leaf of a transgenic (R1 progeny of EL 301A)
plant infected with TMV
35 8C (c) Control WT tobacco infected with TNV.
8D (d) Equivalent leaf of a transgenic (R1 progeny of EL 301A)
40 plant infected with TNV.

45 FIG. 9A is a protein gel and FIG. 9B is a corresponding immuno-blot
probed with an anti-TMV coat protein serum, demonstrating inhibition of TMV
replication in the infected leaf of two individual bO expressing plants compared
to two WT plants. FIG. 9C is a bar graph showing inhibition of *P.s. tabaci*
50 growth in leaves of bO-expressing Samson (EL 301) and SR1 (RM 102; FIG. 1

5 for vector description) plants, indicating an increased disease resistance
compared with the corresponding wild-type plants (WT Samsun, WT SR1). No
bacterial growth was found in mock-inoculated plants. The data presented are
10 the mean and standard deviation from five individual leaves. Conditions for
pathogen infection and analysis are described in Methods, CFU, colony-
forming unit.
15

20 DETAILED DESCRIPTION OF THE INVENTION AND ITS PREFERRED EMBODIMENTS

In an illustrative preferred embodiment of the invention, cells of tobacco
25 plants are transformed with the bO encoding gene. The transformed plants
show enhanced capability to withstand pathogenic attack.

The bO gene is derived from the bacterium *Halobacterium halobium*.
30 The bO gene is described in an article by Nassal et al., 1987.

It has been found that the bO gene material can be introduced into the
tobacco or other higher plant cell in a vector that can be mobilized into plant
35 cells via *Agrobacterium tumefaciens*, such as by a binary vector as shown in
FIG. 1. The bO gene material can also be introduced by other known methods,
40 such as by use of a "gene gun".

The vector structure (EL-301) shown in FIG.1 is as follows:

35S - Ω - Cab-t - bO - Nos 3'

45 The vector was assembled using known methods of biology including
restriction digests, ligation and PCR. The nucleotide sequences of the desig-
nated vectors were determined to confirm the published structures.
50

5 Other bO vectors shown in FIG. 1 are RM-102 (Cab-t segment was
deleted from the structure of EL-301 vector) and RM-101 (bO gene segment of
EL-301 was replaced with GUS segment) were likewise assembled. EL-RM-
10 XX vectors (35S segment of EL-301 and RM-102 will be replaced with
promoters known to be activated upon pathogen attack). They have the
following structures:

15 RM-102

35S - Ω - bO - Nos 3'

20 RM-101

35S - Ω - Cab-t - GUS - NOS 3'

EL-RM-XX

25 (1) PRP - Ω - Cab-t - bO - Nos 3'

(2) PRP - Ω - bO - Nos 3'

30 The backbone vectors were purchased through commercial sources (SK
pBluescript from Stratagene and pBI 100 series from Clontech). The following
is a description of other sources and methods used to obtain the different com-
35 ponents of the construct:

- 40 a. 35S promoter of cauliflower mosaic virus was obtained by restriction digest
from the pBI121 vector.
- b. Chlorophyll A/B binding protein-transit peptide was obtained by PCR from
total soybean genomic DNA.
- 45 c. Omega translation enhancer sequence was obtained by PCR based on
published sequence.

5 d. bO gene was subcloned from a plasmid containing an artificial gene encoding the bO protein (given by Dr. Mark P. Krebs of Dr. Gobind Khorana's laboratory).

10 e. termination signal was obtained by restriction digest of the pBI121 vector.

15 f. GUS open reading frame was obtained by restriction digest of the pBI121 vector. All portions of the constructs (Figure 1) were initially cloned into pBluescript and sequenced and the final construct was then mobilized into the pBI100 backbone binary vector.

20 In illustration, the EL-301 bO gene vector structure was constructed by the following procedure: The chlorophyll a/b transit peptide (Cab-t) coding region was amplified by polymerase chain reaction from total genomic soybean
25 DNA and fused to the bO gene (gift of G. Khorana, Massachusetts Institute of Technology, Cambridge, MA; Nassal et al., 1987). The Cab-t/bO fusion gene was then fused to a synthetic Ω translation enhancing sequence and inserted
30 downstream from the cauliflower mosaic virus 35S promoter (Figure 1A). The 35S - Ω - Cab-t - bO - Nos (noapline synthase) 3' construct was inserted into a
35 T-DNA pBI100 backbone plasmid (Clontech) and mobilized into tobacco (*Nicotiana tabaccum cv Samsun NN*) plants via *Agrobacterium tumefaciens* mediated transformation (Fraley et al., 1985). Individual transformants were
40 screened for the expression level of the bO transgene by RNA gel blot analysis. Other bO gene vectors such as EL-301 vector variants can be conducted which are effective in providing enhanced capability by plants to withstand
45 pathogenic attack.

50 The following is a discussion of biological mechanisms or pathways involved in the increased resistance of higher plants transformed with this invention.

5 During the HR, the recognition of a pathogen induces a rapid cell death
process that results in the formation of a zone of dead cells around the site of
infection. This HR lesion is believed to inhibit further spread of the pathogen
10 and to generate a signal that activates host defense mechanisms and, in many
cases, induces long-lasting systemic resistance to a broad spectrum of patho-
15 gens (Ross, 1961). Induction of such systemic resistance is termed systemic
acquired resistance (SAR) and is accompanied by an increase in the rate of
synthesis of several pathogenesis-related (PR) proteins and the accumulation of
20 salicylic acid (SA) (Malamy et al., 1990; Metraux et al., 1990; Ward et al.,
1991). In certain instances, however, at least some of these host defense
mechanisms can be activated in the absence of a pathogen. These include a
25 variety of maize, barley, tomato, and arabidopsis mutants that develop spon-
taneous lesions similar to lesions caused by a pathogen attack. These mutants
are often termed "disease lesion mimics" and are thought to develop lesions that
30 resemble necrotic disease symptoms or HR lesions in the absence of a pathogen
(Neuffer and Calvert, 1975; Hoisington et al., 1982; Walbot et al., 1983;
35 Wolter et al., 1993). The occurrence of these mutants, especially mutants that
spontaneously develop lesions that resemble HR lesions (HR-type lesions),
provides evidence for the involvement of a genetically defined pathway for cell
40 death during the HR. Thus, plants may contain a pathway for cell death that
can be spontaneously activated in the absence of a pathogen.

45 It has been demonstrated recently that in some of the Arabidopsis lesion
mimic mutants the appearance of HR-type lesions is also coordinated with acti-
vation of host defense mechanisms, such as PR protein induction, phytoalexin
50 production, and accumulation of SA (Dietrich et al., 1994; Greenberg et al.,
1994). Interestingly, as many as 60 to 80 different loci specifying a lesion

5 mimic phenotype were identified in maize (Pryor, 1987; Walbot, 1991). Such a
large number of different loci may suggest that the spontaneous activation of
10 the HR cell death program is not only the outcome of mutations in a specific
pathogen recognition gene but may also be the result of mutations that alter
cellular homeostasis. The unbalanced biochemical state induced by such a
15 mutation may be misinterpreted by host cells for a pathogen infection, resulting
in the triggering of the HR cell death pathway (Dietrich et al., 1994). Addi-
tional support for this model stems from reports that the perturbation of the
20 ubiquitin-dependent protein degradation pathway (Bachmair et al., 1990;
Becker et al., 1993) and expression of certain transgenes in tobacco plants
(Takahashi et a., 1989; Elkind et al., 1990) induce lesion formation. However,
25 in addition to lesion formation, these plants exhibit several other phenotypes,
including abnormal or suppressed growth. This may indicate that perturbing
cellular homeostasis by the expression of these transgenes and by inhibiting the
30 ubiquitin system may have resulted in a general nonspecific effect on cellular
metabolism. In addition, none of the genes responsible for the "disease lesion
mimic" phenotype has been cloned.

35 By this invention, the expression of the bacterial proton-channel bO
gene illustrated in transgenic tobacco results in a phenotype that is very similar
40 to the "disease lesion mimic" mutants. HR-type lesions were formed and
multiple defense mechanisms were activated in the absence of a pathogen.
Transgenic plants expressing the bO gene also exhibited heightened disease
45 resistance against certain viral and bacterial pathogens (FIGS. 8 and 9).
However, in contrast to other transgenes that induce lesions, bO-expression did
not result in abnormal or suppressed growth except in cases of very high
50 overexpression.

RESULTS

5 Expression of bO gene in higher plants has been shown to result in a
"disease lesion mimic" phenotype. A gene was introduced from *Halobacterium*
10 *halobium* encoding bO (Krebs and Khorana, 1993) into tobacco (*Nicotiana*
tabacum cv. Samsun NN). Functioning as a light-driven proton pump that
15 utilizes a different light spectrum from that used by the photosynthetic
apparatus of higher plants, the bO proton-pump may increase the photo-
synthetic capacity of these plants when supplied with its chromophore retinal.
20 In order to direct the bO protein into the thylakoid membrane, the bO gene was
fused to the soybean chlorophyll a/b binding protein transit peptide (Figure 1A,
EL 301, Cab-t). Different families of transgenic tobacco plants were generated
25 that vary in the level of expression of the Cab-t/bO fusion gene, presumably
due to insertion of the gene into different regions of the plant genome and/or
different copy numbers of the transgene (Figure 1B). Transgenic plants ex-
30 pressing the bO gene were found to contain detectable levels of the mature bO
protein (Figure 1C) indicating that the Cab-t/bO fusion protein was processed
to its mature form in plants.

35 Introduction of the bO gene into the tobacco genome produced a pheno-
type very similar to that of the "disease lesion mimic" mutants (Fig. 2A and B).
40 Transgenic tobacco plants expressing the bO gene developed distinct HR-type
lesions on leaves and stems. However, these plants did not exhibit growth or
developmental abnormality. The number and size of spontaneous lesions were
45 roughly correlated with the expression level of the bO transgene.

5 **Formation of spontaneous lesions is coordinated with activation of host
defense mechanisms**

10 Since the appearance of spontaneous lesions in the transformed plants
indicated that the introduction of the bO gene into the tobacco genome may
have activated some general plant defense mechanisms, the expression levels of
several PR proteins were examined. Transgenic plants expressing the bO gene
15 produced high levels of PR proteins in a constitutive manner both in tissue
culture and under normal growth conditions (FIG. 5). Among these: PR-1 is
usually synthesized in response to viral attack; PR-2 encodes a β -1,3-
glucanase which may serve as an anti-bacterial/fungal enzyme; and PR-3
20 encodes an anti-fungal enzyme, chitinase (Linthorst, 1991). Phenylalanine
ammonia-lyase (PAL), a key enzyme in the phenylpropanoid pathway involved
in the biosynthesis of phenolic compounds (Bowles, 1990), also appeared to
increase in its expression level. Several PR proteins were found in the
30 intercellular fluid of leaf tissue from bO-expressing plants (FIG. 6). The
pattern of synthesis of these PR proteins was similar to that occurred in TMV-
infected Samsun NN wild-type plants, supporting the similarity observed
35 between the spontaneous lesions and TMV-induced lesions. This similarity
also suggests that expression of the bO gene may trigger the same host defense
mechanism that is naturally activated by a TMV infection. In addition, as
40 shown in FIG. 4, both the lower (lesion containing) and upper (no lesions)
leaves of bO-expressing plants contained very high levels of SA compared to
wild-type tobacco. Since SA is thought to mediate the process of SAR in
45 tobacco (Enyedi et al., 1992), this observation is consistent with a constitutive
activation of SAR in bO-expressing plants. Furthermore, the appearance of
50 spontaneous lesions was accompanied by accumulation of autofluorescent

5 compounds around the lesions and in the cell walls of collapsed cells within the
lesions (FIG. 7). This may be indicative of cross-linked phenolics that serve to
strengthen cell walls against an invading pathogen (Dietrich et al., 1994).
10 Accumulation of autofluorescent material did not occur in response to
wounding by dry ice, suggesting that the bO-derived lesions were not simply
the result of cellular injury but rather appear to be the outcome of HR
15 activation. Thus, introduction of the bO gene into the tobacco genome has
been shown to result in the spontaneous activation of several components of the
plant defense mechanism against an invading pathogen. These included the
20 triggering of an HR-type cell death response in the absence of a pathogen,
induction of several PR proteins, accumulation of autofluorescent material and
high levels of SA. Activation of host defense mechanisms in the absence of a
25 pathogen is similar to the activation of defense mechanisms in some of the
"disease lesion mimic" mutants recently described in *Arabidopsis* (Greenberg et
al., 1994; Dietrich et al., 1994).
30

35 Induction of systemic resistance against viral and bacterial pathogens

Several of the "disease lesion mimic" mutants exhibited a heightened
disease resistance against a variety of pathogens (Wolter et al., 1993; Green-
40 berg et al., 1994; Dietrich et al., 1994). To ascertain whether the constitutive
activation of plant defense mechanisms in bO-expressing plants confers disease
protection, bO-expressing plants were challenged with TMV and tobacco
45 necrosis virus (TNV). Transgenic tobacco plants expressing the bO gene
developed very few HR lesions in response to a TMV challenge and success-
fully blocked TNV necrotic symptoms (FIG. 8). These results are very similar
50 to the response of SAR-induced tobacco plants upon subsequent pathogen

5 infection (Ross, 1961; Ward et al., 1991). Thus, the formation of few HR
lesions upon TMV challenge and the blocking of TNV necrotic symptoms are
10 indicative of a heightened disease resistance state induced by expression of the
bO gene. Further testing was done on whether the formation of only a few HR
lesions on the infected leaf of bO-expressing plants was the outcome of suc-
15 cessful inhibition of virus replication. As shown in Figures 9A and 9B, bO-
expressing plants were superior to wild-type plants in their ability to block the
replication of TMV in the infected leaf. This inhibition of TMV replication
20 may explain the formation of very few HR lesions on plants with induced
systemic resistance. The amount of TMV particles in the infected leaves of
these plants may be insufficient to trigger the HR response.

25 The resistance of bO-expressing plants to a bacterial challenge was
tested. Transgenic plants expressing the bO gene exhibited a higher degree of
resistance to the bacterial pathogen *Pseudomonas syringae pv. tabaci*. As
30 shown in FIG. 9C, plants expressing the bO gene successfully blocked the
growth of bacteria.

35 These results show that the heightened disease resistance exhibited by
bO-expressing tobacco plants is similar to pathogen-induced SAR (Ross, 1961;
Ward et al., 1991). This observation suggests that expression of bO in higher
40 plants may be misinterpreted by the plant for a pathogen challenge and that the
bO gene action may be similar to some of the "disease lesion mimic" mutations
(Greenberg et al., 1994; Dietrich et al., 1994).

45 **Functional analysis of bO in plants**

50 Bacterio-opsin is a light driven proton-channel that requires the presence
of the chromophore retinal in order to function (Krebs and Khorana, 1993).

5 However, retinal is not thought to be present in higher plants. It is therefore
puzzling and unpredictable that the bO protein may have such a dramatic effect
on plants. It is possible that the bO protein, when expressed in plants, may still
10 function as a passive proton channel which causes leakage of protons. In order
to address the question of bO protein function and to test if this function may
involve some proton-pumping properties of the bO protein, a mutated form of
15 bO was expressed that has a single amino acid substitution (Asp to Ala) at
position 85 (D85A). This amino acid substitution renders the bO protein
incapable of active proton pumping due to an alteration in the charge
20 translocating path through the "proton channel" (Otto et al., 1990). However,
this mutant preserves the ability to reconstitute with retinal to form a pigment
that is very similar to wild-type bacteriorhodopsin. Thus, the protein folding
25 properties of this mutant are likely not affected significantly (Krebs and
Khorana, 1993). Transgenic plants expressing this D85A mutant did not
develop spontaneous lesions, did not exhibit elevated levels of PR-1 and in
30 contrast to bO-expressing plants did not show heightened disease resistance.
However, transgenic plants expressing the D85A mutant did synthesize the
35 mutated bO protein to similar levels as bO-expressing plants. These results
suggest that the bO protein may require some active or passive proton-pumping
properties for eliciting its lesion mimic phenotype.
40

 It will, however, be understood by those skilled in the art that some
mutated forms of bO will be effective to enhance the resistance of higher plants
45 to transgenic attack.

 In summary, transgenic plants expressing the bO gene exhibit many
characteristics of a "disease lesion mimic" mutant. These include the formation
50 of HR-type lesions, the activation of host defense mechanisms in the absence of

5 a pathogen and the induction of heightened disease resistance similar to pathogen-induced SAR (Greenberg et al., 1994; Dietrich et al., 1994).

10 Disease lesion mimic mutants were classified into two major groups: initiation mutants and feedback or propagation mutants (Walbot et al., 1983, Dietrich et al., 1994; Greenberg et al., 1994). Initiation mutants form lesions whose growth is determinate, therefore giving rise to lesions with a defined border. These mutants are thought to be defective in regulating the trigger of the HR response, and may either lack a negative regulator of HR activation (a recessive mutation; see *lsd3*, *lsd5*, Dietrich et al., 1994) or constitutively activate an HR signaling component (a dominant mutation, see *lsd2*, *lsd4*, Dietrich et al., 1994; Neuffer and Calvert, 1975). Propagation mutants form lesions that spread indeterminately, eventually resulting in the death of the entire leaf. These mutants are presumed to be defective in down-regulating the process of lesion progression (a recessive mutation; see *lsd1*, Dietrich et al., 30 1994; *acd1*, Greenberg and Ausubel, 1993; *acd3*, Greenberg et al., 1994). Transgenic plants expressing the *bO* gene mimic dominant initiation mutants. The dominant nature of the *bO* transgene also support the assumption that the *bO* action results in the constitutive activation of a pathogen response signal. Since the *bO* gene induced spontaneous lesion formation in several different tobacco cultivars (*Samsun NN*, *Xanthi-nc nn* and *SR1*, Mittler and Lam, unpublished data) and in transgenic *Arabidopsis* plants (Marques and Lam, unpublished data), it is unlikely that it functions by mimicking the infection of a specific pathogen. The expression of the *bO* gene may therefore affect the activation of the *pcd* pathway at a relatively basic level that is common to different plants. 50

5 It has been previously suggested that some of the dominant lesion initia-
tion mutants perturb cellular homeostasis. The resulting unbalanced biochemi-
cal state may be misinterpreted by the host cells as a pathogen infection and
10 trigger the HR. Since bacteriorhodopsin is a light driven proton-pump, its ex-
pression in higher plants may result in an artificial increase in proton-pumping
activity that may perturb the natural ionic homeostasis of the cell. However,
15 plants are presumed to lack retinal which is required for the active pumping of
protons. In addition, *Halobacterium halobium* cells deficient in retinal biosyn-
thesis accumulate mature bO protein, suggesting that at least in the bacterial
20 system bO does not cause leakage of protons. However, the expression of the
D85A mutant which is incapable of active proton-pumping does not result in a
lesion mimic phenotype. This finding suggests that the bO protein may require
25 some properties that involve proton translocation across membranes for eliciting
its action as a lesion inducer gene. It may be possible that expression of the
bO gene in higher plants alters cellular homeostasis through unbalanced leak-
30 age of protons. Such perturbation of cellular homeostasis may in turn trigger a
HR pathway. It should be noted that the triggering of the HR in tobacco cells
35 by certain bacterial pathogens requires the activation of a plasma membrane K⁺
efflux/net H⁺ uptake exchange. In addition, the induction of this altered bio-
chemical balance depends on a plasmalemma H⁺-pumping ATPase activity
40 (Atkinson and Baker, 1989). Alteration of the proton pumping homeostasis by
the bO gene may induce a similar altered biochemical balance causing the
45 spontaneous triggering of a HR pathway.

50 Since the bO gene functions as a lesion inducer in at least two different
plant species and since induction of systemic resistance, similar to SAR, is ex-
pected to confer disease protection against a variety of viral, fungal and bacte-

5 rial pathogens (Lawton et al., 1993), the bO gene may be useful as a general
agronomic tool to enhance disease protection in different cultivars against a
variety of pathogens. Application of the bO gene may involve screening for
10 transgenic lines that express the bO gene at a moderate level, causing the for-
mation of few spontaneous lesions, yet conferring disease protection. Alter-
natively, inducible expression of the bO gene by a regulated promoter may
15 allow controlled activation of the plant defense mechanism, thus mimicking the
time for which the defense mechanism will be turned on.

20 **RNA isolation and analysis**

Leaves were collected, frozen in liquid nitrogen and ground to a powder.
25 RNA was then extracted as described by Nagy et al. (1987) and analyzed by
northern blots. Northern blots were first hybridized with either the bO or PR
and PAL probes and then with a probe for 18S rRNA. Northern blot hybridi-
30 zation and membrane washing were performed using Duralose-UV membranes
and quickHyb solution (Stratagene) as suggested by the manufacturer. PR1,
PR2 and PR3 transcripts were detected with the corresponding tobacco cDNAs
35 as probes (gift of Dr. D. Klessig), and the level of PAL transcript with a corre-
sponding parsley cDNA as a probe (gift of Dr. K. Hahlbrock).

40 **Protein Isolation and Immunodetection**

45 Immunodetection of PR-1, bO and TMV coat protein was performed by
western blot analysis of total leaf protein with a chemiluminescence detection
system (Renaissance kit from DuPont). Monoclonal Anti-PR1 antibody was a
50 gift of Dr. D. Klessig, monoclonal anti-bO antibody was a gift of Dr. G.
Khorana and anti-TMV coat protein serum was a gift of Dr. N. Turner. Detec-

5 tion of PR proteins in the intracellular fluid of bO-expressing or TMV infected tobacco plants was performed according to the Lawton et al. (1993).

10 **Salicylic Acid Determination**

SA was extracted from leaf samples (0.3g) and quantified by HPLC. Total SA (the sum of free and glucose-conjugated SA) was determined and corrected for SA recovery as previously described (Yalpani et al., 1993).

20 **Pathogen Infection and Analysis**

Fully expanded young leaves were infected with equal amounts of TMV strain U1 or TNV strain A, in 5 mM potassium phosphate buffer, pH 7, or mock infected with the same 5 mM phosphate buffer, by gently rubbing the leaves with carborundum. Plants were either kept at 22°C or 30°C under continuous light. Lesions were photographed 72 hours post-infection. No lesions developed on mock infected leaves of wild-type and transgenic bO-expressing Samsun NN plants. The progression of lesion formation following a temperature shift from 30°C to 22°C, of bO-expressing and TMV infected plants, was assayed by measuring ion leakage from leaf discs obtained at different time points following the shift. For each measurement, 5 leaf discs (7 mm diameter) were floated abaxial side up on 6 ml of distilled water for 4 hours at room temperature. Following incubation, the conductivity of the bathing solution was measured with a Model 604 (VWR Scientific) conductivity meter. Measurements for each time point were performed in triplicate. Inoculation of plants with *Pseudomonas syringae pv. tabaci* (ATCC 11528) was performed by infiltrating the leaves with a 1 ml syringe without a needle. Seventy-two hours following infiltration of leaves with bacteria (500 or 15,000 CFU/cm², in

5 sterile distilled water), the leaves were surface sterilized with 20% bleach/0.1%
tween 20 for 1 min and washed three times with sterile distilled water. Leaf
discs (10 mm diameter) were taken from the infection site, ground in sterile
10 distilled water, diluted and plated on nutrient agar. No bacterial growth was
observed with leaf discs obtained from mock inoculated plants that were
infiltrated with sterile water.
15

Example

Construction of an Expression Vector for the Overproduction of Bacterio- opsin in Higher Plants by Agrobacterium Mediated Transformation

20

The construction of the EL301 vector consisted of two major parts. The
25 first set of manipulations involved putting together a general vector (designated
as EL301) for plant gene expression that incorporates the omega sequence of
the Tobacco Mosaic Virus leader sequence into the 5' region of the desired
30 transcript. As previous work by Gallie et al. (1987) have shown, this should
substantially increase the translation efficiency of the RNA of interest. The
35 second part consisted of the insertion of the synthetic bO gene (Nassal et al.
1987) fused to a sequence encoding the chloroplast-targeting transit peptide
from the soybean Cab3 gene (Walling et al. 1988) into the polylinker sites that
40 are present in our general expression vector EL103. The resultant vector was
designated as EL301. The following is a detailed description of the steps
involved.
45

5 Part 1: Construction of the general expression vector for foreign protein pro-
10 duction in higher plants.

a. The Omega sequence of TMV was amplified from pJII103 (Gallie et al.
1987) by PCR using two primers:

EL174 5'-GCTCTAGATATTTTTACAACAATTACC-3'

EL175 5'-CGATCCGGATCCTGTCTCTTGA-3'

15 These primers introduce an XbaI site immediately upstream from the
Omega sequence and a BamHI site down stream from the 3' end of Omega.
20 These are underlined in EL174 and EL175, respectively.

b. The amplified fragment was digested with the restriction enzymes XbaI and
25 BamHI and was then subcloned into the vector pBI121 (purchased from
Clontech Co.) at the same sites. This places the Omega sequence between
the 35S promoter of CaMV (cauliflower mosaic virus) and the β -glucuronidase
(GUS) reporter gene. A unique HindIII site is present upstream of the
30 35S promoter while an SstI site is present downstream of the GUS gene.

35 c. The XbaI site was then removed by blunting with Klenow fill-in after di-
gestion with XbaI. The polylinker region in the pBluescript II SK
40 (Stratagene) enclosed by BamHI and SstI sites were then used to replace the
GUS gene sequence using the BamHI and SstI restriction sites, giving rise
to a construct called pZM24. This effectively replaced the GUS gene with a
45 polylinker region containing the restriction sites BamHI, SpeI, XbaI, NotI,
SacII and SstI.

- 5 d. The HindIII/EcoRI fragment (35S promoter-Omega-nos 3' terminator) from
pZM24 was then exchanged with the 35S-GUS-nos 3' sequence in pBI121
10 (purchased from Clontech Co.). The vector pBI121 is derived from pBIN19
which is a disarmed *Agrobacterium* vector that allows for plant transforma-
15 tion via this soil bacterium (Bevan, 1984). The final vector, designated as
EL103, contains three unique restriction sites located between the Omega
sequence and the Nos-3' terminator sequence from the nopaline synthase
gene of the *Agrobacterium* T-DNA.

20 Part 2. Amplification of the Cab3 transit peptide from soybean genomic DNA
and cloning of bO gene fusion into expression vector.

- 25 a. The genomic DNA of soybean (*Glycine max*, cv. Corsoy) was used to am-
plify the transit peptide from the Cab3 locus (Walling et al., 1988). The
primers used were:

30 EL60 5'-GATCGATATGGCAGCAGCTTCTTCC-3'

EL61 5'-GAAGCTTGCTCACCCCTTCCACATCC-3'

35 The primers were designed to insert a ClaI site and a HindIII site at the 5'
and 3' portion of this transit peptide sequence, as indicated by the under-
lined nucleotides. After PCR under standard conditions (35 cycles of:
40 94°C, 1 min.; 55°C, 1 min.; 72°C, 1 min.), the amplified fragment was di-
gested with HindIII and ClaI. This fragment was designated as Cab-t.

- 45 b. The fragment was then ligated to a pBluescript SKII vector (cut with
EcoRI/ClaI) and the bO gene plasmid from Dr. Knorana (cut with
50 HindIII/EcoRI). The resultant fusion, designated as Cab-bO, between the
Cab-t sequence and bO was confirmed by sequence analysis. A single base

5 difference was found in our PCR product from that of the published Cab3
sequence. This changed a valine amino acid upstream from the predicted
10 processing site into a cysteine residue.

15 c. The ClaI/SstI fragment containing the Cab-t/bO fusion gene was isolated
from our clone Cab-bO and inserted into EL103. The ClaI site was blunted
by Klenow fill-in and then the fragment isolated from Cab-bO after SstI di-
20 gested. This was subcloned into EL103 vector that has been cut with
BamHI, filled-in with Klenow and then digested with SstI. The resultant
clone is designated as EL301. This is a construct for overexpression of bO
25 in higher plants.

**Expression of bO in Arabidopsis thaliana also result in spontaneous lesions
and induction of defense responses.**

30 The construct EL301, described above, has been introduced into
Arabidopsis thaliana (ecotype RLD) by Agrobacterium-mediated transforma-
35 tion. The transformed plants showed spontaneous lesions in mature rosette
leaves that exhibited similar morphology to those observed with our transgenic
tobacco plants. Furthermore, when examined by fluorescence microscopy, they
40 showed UV-fluorescent material in and around these lesion sites. This is
similar to those observed in lesions arising from an incompatible interaction
between plants containing resistance genes and pathogens containing the
45 corresponding avirulence genes (Greenberg et al., 1994). We have also deter-
mined the level of the major phytoalexin of Arabidopsis, called camalexin, in
50 these transgenic plants containing the construct EL301. We found an approxi-
mately 3 to 4 fold increase in camalexin levels in transgenic leaves without

5 visible lesions. In leaves showing a large number of spontaneous lesions, we
observe about a 100 fold increase in camalexin levels. Since phytoalexins are
antimicrobial compounds, it is expected that this overproduction should lead to
10 significant increase in resistance to bacterial and fungal pathogens. The sali-
cylic acid (abbreviated as SA) content of our transgenic plants has been deter-
15 mined since it is believed that SA is an important signal for the induction of
plant defense genes. About a 20-fold increase has been found in SA content in
transgenic *Arabidopsis* plants that expressed spontaneous lesions in response to
20 the expression of bO. These results are consistent with expectation that bO
expression can be used in divergent plant species to induce the latent defense
responses that are normally activated only upon an incompatible interaction.

25 Testing the effects of bO expression in monocots

30 Genetic mutants from certain monocot plant species, such as maize and
barley, have been characterized which showed a disease lesion mimic pheno-
type. One such locus of barley, called *mlo*, shows heightened resistance to
35 fungal pathogens. This is similar to that observed with some of the lesion
mimics found in dicots species, such as tomato and *Arabidopsis*. The bO trans-
gene should induce spontaneous lesions as well as defense responses in
40 monocots as well. The bO expression cassette is being introduced into
turfgrass. The methodologies have been worked out for the construction of
45 transgenic monocots, such as turfgrass (Hartman et al., 1994). For these
species, the selection marker that will be used is the bacterial bar gene that
confers resistance to Biolafos, a commercial herbicide.

5 The bO gene in like manner is being introduced into other monocot
species, for example, maize and rice.

5 **What is Claimed is:**

- 10 1. A transgenic plant cell which expresses a bacterial gene encoding bacterio-
opsin (bO), whereby a plant having said transgenic cells has an enhanced
15 capability to withstand pathogenic attack.
2. A transgenic plant cell of Claim 1 wherein the plant is a dicot species.
3. A transgenic plant cell of Claim 1 wherein the plant is a monocot species.
- 20 4. A transgenic plant having transgenic cells which express a bacterial gene
encoding bO, whereby said plant is provided with superior capability to
25 withstand pathogenic attack.
5. A transgenic plant of Claim 4 which is a dicot species.
- 30 6. A transgenic plant of Claim 4 which is a monocot species.
- 35 7. A method for enhancing resistance of a higher plant to attack by one or
more plant pathogens by transforming cells of said plant with the bO
40 encoding gene.
8. A method of Claim 7 wherein the plant is a dicot species.
- 45 9. A method of Claim 7 wherein the plant is a monocot species.
- 50

5 10. A method of Claim 7 wherein the cells of said plant were transformed using
 a binary bO gene vector.

10 11. A method of Claim 10 wherein the binary bO gene vector is EL-301 or a
 variant thereof.
