(54) Title: IMPROVED CLEAT FOR AN ATHLETIC SHOE

(57) Abstract

A cleat (10) for an athletic shoe includes a base plate (11) and a blade (13) having a tapered and slightly curved ground-engagement member (15) and a support member (17) for coupling the engagement member to the base plate. At least one notch (61) is defined by the base plate, the support member and the engagement member for receiving bonding material to attach the cleat to a shoe sole. The configuration of the base plate and blade is such that the cleats may be arranged in closely spaced or abutting relationships. An athletic shoe sole includes an array of such cleats disposed along a substantially circular path to define an annular cleat array, with the cleat blades generally in registry with the path. Pivoting movements are facilitated.

DESIGNATIONS OF "DE"

Until further notice, any designation of "DE" in any international application whose international filing date is prior to October 3, 1990, shall have effect in the territory of the Federal Republic of Germany with the exception of the territory of the former German Democratic Republic.

20 Title: IMPROVED CLEAT FOR AN ATHLETIC SHOE

Field of the Invention

25 This invention is related generally to athletic shoes of the type having cleats for penetrating ground engagement and, more specifically, to shoes with annular cleating for pivotability. Still more particularly, this invention relates to shoes with blade-like cleats of the type generally referred to as spikes and to such cleats.

Background of the Invention

30 Certain athletic shoes for field sports such as baseball have a number of blade-like cleats (or "spikes") for the purpose of increasing traction. Such cleats or spikes dig into the ground to prevent slipping during starting, stopping and cutting maneuvers.

35 However, in addition to providing desirable traction for starting, stopping and cutting, such cleats typically

1 provide undesirable resistance to pivoting. This can be a
disadvantage in at least two ways.

5 First, the resistance of many prior art cleating
arrangements to turning movements can create stresses
within the leg when unwanted torque or force is applied to
the athlete, particularly to the athlete's leg. Injuries,
particularly knee and ankle injuries, can result if a
twisting movement is forcibly applied to a leg at a time
when the cleats are firmly planted in the turf and release
is difficult or impossible.

10 Second, when pivoting is inhibited, maneuverability
of the athlete is limited, thus making performance less
than it could be. Enhancing the ability of a player to
pivot while still maintaining good traction and foot
stability can greatly increase effectiveness on the field.

15 When pivoting is inhibited, the maneuverability of
the athlete is limited and performance is less than it
could be. Enhancing the ability of a player to pivot while
yet maintaining or improving stability and traction in foot
motions not involving pivoting can greatly increase
effectiveness on the field.

20 Pivotability is of great importance in baseball in a
number of common motions. For example, pivoting is
important in batting to avoid certain unnatural motions
which occur because of poor pivotability, in pitching on
both the lead foot and the drive foot, in fielding such as
in turning to make a throw.

25 Attention has been given to improving pivotability in
cleated athletic shoes. One example of a blade-like cleat
is shown in United States Patent No. 4,347,674, which shows
three arcuate spikes widely spaced along a circular path to
facilitate pivoting. Both the configuration of such
cleats, with their flat ends which are vertical (that is,
perpendicular to the main sole surface), and the widely
spaced arrangement of such cleats, spaced apart in fact by
35 dimensions well in excess of spike width, are such that any
resulting improvement in pivotability will not be very

1 substantial. The configuration and spacing of such cleats
is not conducive to excellent pivotability.

Such vertical ends are disadvantageous because they
present a long edge for cutting the full depth of the
5 penetrated ground during pivoting motions. This edge
arrangement results in fairly high resistance to pivoting.
And, the wide spacing means that fresh ground or turf is
being cut for most or all of many pivoting motions.

In addition, such blade cleat has a distal edge which
10 is generally parallel to the main sole surface along all or
nearly all the width of the cleat. Such relatively long
sole-parallel distal edge presents a surface which is more
resistive to penetration of the ground. With such a cleat,
it becomes more difficult to penetrate ground with harder
15 surfaces, especially for players of lighter body weight.

In addition to the structural features described
above, there are other structural features of prior
blade-like cleats which are disadvantageous in certain
situations. Some background discussion is necessary for
20 proper understanding.

First, attention is drawn to the recent developments
in athletic shoe cleating made by Michael L. Tanel, the
inventor herein, involving annular cleating which provides
a combination of greatly improved pivotability and
25 excellent traction. These developments tend to reduce the
chance of athletic injuries and significantly improve
maneuverability on the field. Examples of such cleating
are disclosed in United States Patent Nos. 4,577,422,
4,653,206, 4,660,304, 4,669,204, 4,723,365 and 4,748,752.

The improvement in pivotability made possible with
30 shoes in accordance with the principles of such patents is
dramatic, and such shoes give the athletes wearing them a
natural feeling of freedom together with good feeling of
traction for stopping, starting and cutting.

These Tanel inventions have been commercially
35 embodied in shoes having cleats which are integrally formed
with soles and have tapered sides, rather than in

1 spike-like cleats. One significant feature of such annular
cleating arrangements is the substantially continuous
nature of an annular cleat. Such a degree of continuity
becomes somewhat problematic when blade-like cleating,
5 using metal or other rigid material, is contemplated.

Blade-like cleats like those in the aforementioned
Patent No. 4,347,674 have a base plate which is attached to
the blade portion of the cleat at generally right angles
and which is used for securing the cleat to the sole of an
10 athletic shoe. Attachment may be by threaded fasteners or
by injection molding a bonding material over the base
plate. Characteristically, such base plates of blade-like
cleats of the prior art have a width which is significantly
greater than the width of the blade to which they are
15 attached. Such greater width is deemed essential to
firmness of attachment to the sole, particularly when
attachment is by securement by virtue of injection molding
over the base plate.

However, to obtain the benefits of pivotability of
20 substantially continuous annular cleating, and to do so
without loss of sole flexibility, close spacing of discrete
blade-like cleats is essential. Indeed, abutting or nearly
abutting cleats is highly desirable. Such cleat "density"
provides improved traction with little or no impairment of
25 pivotability.

Unfortunately, the undue width of earlier cleat base
plates rules out such close or nearly abutting arrangement
of cleats. As a consequence, with such blade-like cleats
of the prior art it has not been reasonably possible to
30 construct an athletic shoe which maximizes cleat density
for maximum traction. And, to merely reduce the width of
the cleat bases would tend to substantially weaken the
engagement of the cleat with the sole.

Another very practical consideration for athletic
35 shoes which would have an annular arrangement of closely
spaced cleats relates to the fact that athletic shoes
obviously must come in a wide variety of sizes. Because

1 of such wide variations in size, a wide variety of cleat
sizes and widths could be thought to be necessary. This
would complicate manufacturing and greatly increase
manufacturing costs. The presence of multiple cleat sizes
5 at the assembly station would tend to cause manufacturing
errors such as selecting a cleat of improper size for a
particular shoe being assembled. A universal cleat would
be highly desirable.

Referring again to ease of ground penetration,
10 consideration must also be given to the total area of the
cleat edges which initially engage the turf. The greater
the total area bearing on the turf, the more difficult it
may be for a cleat to penetrate the ground; the smaller the
total area bearing on the ground, the easier it may be for
15 a cleat to penetrate. Reducing the blade width reduces the
area of the distal ends. However, structural weakness may
result from reduced cleat width and cleat deformation or
breakage will likely result.

To the extent that reducing cleat width adds
20 sharpness, there would be an increased risk of "spiking"
injury. And, regardless of width, sharp corners between
the vertical sides of certain prior art cleats and their
long horizontal distal edges can pose an undue risk of
injury.

25 Still another problem with certain cleated shoes of
the prior art is that the pressure of the individual cleats
can be felt by the foot of the athlete. Because of this,
shoe comfort is reduced. The aforementioned annular cleats
tend to overcome this problem, but for shoes with discrete
blade-like cleats, this problem can be significant,
30 particularly on hard ground.

Yet another concern with certain blade-cleated shoes
of the prior art is that their low number of cleats on the
forefoot provides insufficient traction during certain
movements. Traction through a wide range of athletic moves
35 is highly desirable. And, many blade-cleated shoes of the
prior art have cleating arrangements which do not have

1 sufficient spread to provide good support. In some cases,
insufficient ankle stability is a result.

A few general comments are in order before turning to
a description of this invention. In particular, a brief
5 description of the foot and its pivoting and planted
positions will be helpful. This can serve as an aid in
understanding certain embodiments of this invention.

The sole of the foot includes four portions. These
are, in order from back to front: the heel portion; the
10 arch portion; the ball-of-the-foot portion; and the toe
portion. The heel portion and the ball-of-the-foot portion
are those portions which share most if not all of the
player's weight when the player is in a normal standing
position with feet generally flat on the ground. In such
15 position, the arch portion and toe portion bear little if
any weight.

When a player is "on his toes" in a "ready" position,
virtually all of the player's weight is normally shared by
the toe portion and the ball-of-the-foot portion. The same
20 is usually true when a player is "digging" in a running
action. Indeed, when a player is in the ready position,
the juncture of the phalanges (toe bones) and the
metatarsals is the center of weight bearing. In other
words, the center of weight bearing in the forward portions
25 of the foot actually moves forward when a player shifts to
the ready position.

The sole of an athletic shoe has portions immediately
below these four portions of the foot which may be
designated, and herein are designated, by the same terms.

30 Objects of the Invention

It is an object of this invention to overcome some of
the problems and shortcomings of the prior art, including
those mentioned above.

35 Another object of this invention is to provide an
improved blade-like cleat.

1 Yet another object of this invention is to provide a
blade-like cleat which facilitates mounting in an annular
abutting relationship with other cleats.

5 Still another object of this invention is to provide
a universal blade-like cleat, which may be used on a wide
variety of shoe sizes.

 Another object of this invention is to provide a
cleat which provides improved pivotability and excellent
traction.

10 Still another object of this invention is to provide
a cleat which provides good traction characteristics upon
hard ground, including hard ground covered with wet grass.

 Another object of this invention is to provide a
cleat which penetrates the ground well without bending or
15 breaking.

 Another object is to provide an improved athletic
shoe sole of the type having blade-like cleats.

 Another object of this invention is to provide an
athletic shoe having both improved pivotability and
20 excellent traction.

 Another object of this invention is to provide an
improved athletic shoe which tends to reduce the risk of
certain common injuries of athletes, particularly knee and
ankle injuries.

25 Another object is to provide an improved athletic
shoe of the type having annular cleating.

 Another object of this invention is to provide an
improved annular-cleated athletic shoe with enhanced ground
penetration.

30 Another object of this invention is to provide a
blade-cleated athletic shoe which reduces the possibility
of ankle injuries.

 Another object of this invention is to provide
improved ground penetration in an annular-cleated shoe
without the need to sharpen the distal edge of annular
35 cleating.

1 Yet another object of this invention is to provide a
cleated athletic shoe exhibiting excellent sole comfort.

 These and other important objects will be apparent
from the descriptions of this invention which follow.

5

Summary of the Invention

 This invention is an improved blade-like cleat for
athletic shoe soles and an improved athletic shoe for field
sports. The invention provides excellent controlled
10 pivotability and traction in a commercially desirable form
particularly useful for baseball and the like.

 A plurality of the improved blade-like cleats of this
invention are disposed on a substantially circular path to
permit easy pivoting movement. The cleats are mounted in
15 an abutting or substantially abutting (closely spaced)
relationship, such that they together form what is
essentially an annular circular edge. Such array of cleats
provides excellent penetration and pivoting characteristics
without compromising traction.

 The configuration of the blade-like cleat of this
20 invention allows mounting to a sole in such abutting
arrangement. The inventive cleat firmly engages the sole
despite its abutting relationship to adjacent cleats. And
the configuration is such that a single cleat configuration
25 allows formation of an annular array for shoes of a wide
variety of sizes.

 The cleat of this invention includes a base plate
with an outer segment having a first width and a tongue for
attachment of the cleat to a shoe sole by embedding it in
30 the material forming the sole. A blade is attached to the
base plate and extends generally perpendicularly from it.
The blade has an engagement member for providing traction
on the ground and a support member for coupling the
engagement member to the plate. The cleat is preferably
35 integrally formed, with all of the aforementioned "members"
thereof being portions of one piece.

1 The engagement member includes a lower shoulder and
an upper tip, the latter to initially engage and penetrate
the surface of an athletic field. The support member has a
second width which is less than the first width, thereby
5 forming a notch between the engagement member and the base
plate. Bonding material may be received in the notch and
over the base plate for attaching the cleat to the sole of
an athletic shoe.

 In a highly preferred cleat, the engagement member
10 will have generally straight edges which are angularly
arranged. These edges extend between the extremities of
the lower shoulder and the corresponding extremities of the
upper tip. The shape of the engagement member thereby
resembles that of a truncated isosceles triangle.

 In a preferred embodiment, the outer segment or edge
15 of the base plate has a width which is generally equal to
the width of the lower shoulder of the engagement member.
In any event, the width of the outer segment need be no
greater than that of the lower shoulder. This permits
20 mounting of cleats in a relationship whereby the lower
shoulder extremities of adjacent cleats may be closely
spaced one to another or may actually abut.

 It is also preferred that the engagement member be
joined to the base plate by a support member. This support
25 member is preferably centered generally midway between the
extremities of the lower shoulder and the outer segment and
has a width which is significantly less than either of the
foregoing. When constructed in that fashion, the lower
shoulder, the support member and the base plate cooperate
30 to define a notch at either side of the cleat. This notch
is used to receive bonding materials such as injection
molded nylon or polyurethane used to attach the cleat to
the sole of a shoe, or to form the sole around such cleat
base.

 The inventive cleats may be arranged in a wide of
35 variety of patterns upon the sole of a shoe. However, for
the athletic shoe of this invention with its annular array

1 of cleats, a plurality of cleats project from the sole and
are disposed along a substantially circular path. This
path encompasses a major area of the ball-of-the-foot and
toe portions. The unique structure of the cleats permits
5 them to be arranged in an abutting or nearly abutting
relationship to each other, in end-to-end fashion. This
arrangement forms what may be described as an annular cleat
which provides improved engagement between the shoe sole
and the surface of the turf.

10 In a highly preferred embodiment, the engagement
member is slightly curved (arcuate) to facilitate pivoting
movement. When the cleat functions as a universal cleat,
suitable for shoes of all sizes, its curvature is set to
follow a perfect circle for a shoe of mid-range size.
15 Thus, if the cleat will be used on shoes from sizes 7 to
16, the curvature for a size 11 or 12 cleat will be used.
It has been determined that such curvature is fully
acceptable for annular arrays throughout the entire size
range. While spacing between cleats will vary slightly,
20 such universal cleat will essentially follow the circles of
all such sizes.

When constructed as described, the inventive cleat
has a distal edge which presents a relatively small area to
the surface of the ground. This enhances ease of ground
25 penetration. In addition, the cleat has edges which
angularly cut through the turf after initial penetration.
This configuration accomplishes two highly desirable
results.

30 First, resistance to initial penetration is low and
increases gradually rather than instantaneously as the
cleat penetration depth increases. Second, as the shoe is
pivoted the angularly arranged edges of the engagement
member will slice through and penetrate turf more readily
than the vertical edges of earlier blade-like cleats. And,
35 because of the close spacing made possible by the cleat of
this invention, pivoting rotation causes a trailing cleat

1 to promptly enter and follow a path cut by a leading cleat,
with only the most minimal initial pivoting necessary to
start such following process. Because of the tapered
edges, as pivoting progresses through such initial stages,
5 there is a continuous reduction in resistance to pivoting
movement.

While it may be recognized that traction is increased
by increasing the number of blade-like cleats on the
forward portion of a sole (sometimes referred to as cleat
10 "density"), other factors will be important. For example,
an athlete needs excellent sole flexibility, particularly
in the ball-of-the-foot portion. Therefore, it is
preferred that the annular cleat arrangement be such as can
promote flexibility, while yet maintaining excellent
15 capability for stopping, starting and cutting.

When mounted in an abutting relationship, adjacent
pairs of the tapered cleats define generally V-shaped
spaces. Sole flexibility is enhanced by positioning cleats
so that opposed pairs of such spaces form a plurality of
20 cross-sole breaks (for example, two) in the annular cleat
array. Such breaks are preferably near the juncture of the
ball-of-the-foot and toe portions of the sole and between
the ball-of-the-foot and arch portions.

The configuration of the inventive cleat may be
25 readily adapted to accommodate specific requirements. For
example, the angles of taper may be changed, the degree of
sharpness of the angled edges and/or the distal edge may be
modified and the projecting length of the cleat may be
changed.

30 The annular array of blade-like cleats of this
invention provides a wide base of cleat engagement, which
tends to reduce the possibility of ankle injuries. The
soles of this invention are also comfortable to wear,
substantially avoiding any feeling of individual cleats as
can occur with certain shoes of the prior art.
35

1 Brief Description of the Drawings

FIGURE 1 is a perspective view of the inventive cleat.

5 FIGURE 2 is an elevation view of the cleat of FIGURE 1 taken along the viewing axis 2 thereof.

FIGURE 3 is a perspective view of a prior art cleat.

FIGURE 4 is a bottom plan view of an athletic shoe sole, devoid of cleats, illustrating the portions thereof.

10 FIGURE 5 is a bottom plan view of an athletic shoe sole in accordance with this invention, having an array of the cleats of this invention.

Detailed Descriptions of Preferred Embodiments

Referring to FIGURES 1 and 2, a universal cleat 10
15 for an athletic shoe includes a base plate 11 and a blade 13 attached to the plate 11 and extending generally normally therefrom. The blade 13 includes an engagement member 15 for providing traction upon an athletic field and a support member 17 for joining the engagement member 15 to
20 the plate 11. The base plate 11 has an outer segment 19 with a curved profile terminating in base extremities 21. An inwardly extending tongue 23 is provided to attach the cleat 10 to the sole, is defined by generally straight edges 25 and terminates in a blunted tip 27. To further
25 facilitate attachment of cleat 10, tongue 23 also includes an aperture 29 which may be of any convenient shape, triangular for example. A way to attach cleat 10 to the sole is described following.

A support member 17 is joined to tongue 23 adjacent
30 outer segment 19 and extends upward to support engagement member 15. One preferred way to form inventive cleat 10 is by stamping and bending and if so formed, support member 17 will exhibit a slight bending radius. To help provide additional rigidity, a small convex dimple 31 is formed in
35 support member 17; in some cases, two or more dimples may be desirable. In a highly preferred embodiment, engagement member 15 tapers upwardly and includes a relatively wide

-13-

1 lower shoulder 33 and a relatively narrow upper tip 35.
Generally straight edges 37 extend between the extremities
39 of lower shoulder 33 and the corresponding extremities
of upper tip 35 so that the shape of engagement member 15
5 resembles that of a truncated isosceles triangle. However,
it is to be appreciated that the angles included between
either of the edges 37 and upper tip 35 need not be equal
one to the other. Special situations may suggest an
engagement member 15 which is tapered to define geometric
10 shapes other than an isosceles triangle.

As described above, conflicts arise from the
configuration of a conventional blade-like cleat and these
were unresolved prior to inventive cleat 10. That is, it
was desirable to have the distal ends of cleats present a
15 total area which was relatively small for initial
engagement of the earth. Inconsistently, the cleat was
required to have a width which was sufficient to provide
acceptable mechanical rigidity against bending forces and
to provide resistance against slipping. The inventive
20 cleat 10 resolves these conflicts in that a relatively
small tip 35 area is presented for initial turf engagement
and penetration. However the overall broad-shouldered
structure of blade 13 is sufficiently robust to resist
bending and breakage.

25 The ease with which tip 35 initially penetrates the
turf may be further improved by the inclusion of a bevel
surface 41, thereby further diminishing the area of the
distal end 43. It is also to be appreciated that unlike an
earlier cleat 45 as shown in FIGURE 3, inventive cleat 10
30 has a distal end 43 which is devoid of 90° corners. The
absence of such sharp corners may help avoid laceration
injuries which commonly occur in baseball.

Before describing other benefits arising from the use
of inventive cleat 10, reference is made to FIGURE 4 which
35 depicts the sole 47 of an athletic shoe devoid of cleats.
The sole 47 has four portions which are defined by the

1 portions for the foot adjacent to them. These sole
portions are: a heel portion 49, immediately below the
player's heel; an arch portion 51, below the arch of the
player's foot; a ball-of-the-foot portion 53, below the
5 ball of the player's foot; and toe portion 55, below the
player's toes.

As previously noted, the ball-of-the-foot and the
heel portions, 53, 49 respectively, bear weight when the
player is in a flat footed stance while the toe and the
10 ball-of-the-foot portions 55, 53 respectively, bear weight
when the player is in the ready position. For some sports
and/or particular types of playing fields, it may be
desirable for a shoe to exhibit very high tractive
capabilities. One approach to this capability is by
15 increasing the number of cleats 10, i.e., the cleat
"density". Concurrently, the player must be able to
quickly and easily pivot the shoe without undue leg and
knee strain.

Referring additionally to FIGURE 5, these two
20 objectives may be accomplished by arranging cleats 10 along
a substantially circular path 57 which encompasses a major
area of the ball-of-the-foot and toe portions 53, 55
respectively. Each cleat 10 is arranged so that blade 13
is generally in registry with the path 57 and so that
25 cleats 10 are in a closely spaced or substantially abutting
relationship to at least one adjacent cleat 10. This
arrangement forms what may be described as an annular cleat
array 59 which extends along a substantially circular path
57 and encompasses a major area of the ball-of-the-foot and
30 toe portions 53, 55 respectively. This array 59 provides
improved engagement between the shoe sole 47 and the
surface of the turf while yet readily permitting pivoting
movement.

Referring again to FIGURES 1 and 2, arrangement of
35 cleats 10 in a closely spaced or abutting relationship is
facilitated by dimensional features of cleat 10. The
distance between extremities 21 of outer segment 19 is

-15-

1 selected to have a width W_1 . The width of support member
17 is selected to have a width W_2 which is less than W_1 and
the extremities 39 of the lower shoulder 33 are selected to
have a width W_3 therebetween. In a preferred embodiment,
5 the width W_2 will be less than width W_1 while the width W_3
will be at least as great as W_1 . In a highly preferred
embodiment, the width W_1 and W_3 will be generally equal one
to the other. When so constructed, outer segment 19,
support member 17 and lower shoulder 33 will cooperate to
10 define at least one notch 61 therebetween. If, for
example, a vertical edge of support member 17 is aligned
with the corresponding extremities 39, 21 of lower shoulder
33 and outer segment 19 respectively and if the described
dimensional relationships are adhered to, cleat 10 will
15 include only one such notch 61. However, in a highly
preferred embodiment, the support member 17 will be
generally centered between the extremities 21, 39 of the
outer segment 19 and the lower shoulder 33 and the cleat 10
will have two notches 61 as shown in FIGURES 1 and 2. When
20 so formed, the extremities 39 of the lower shoulder 33 will
be in a vertically spaced but otherwise generally
coterminous relationship to the corresponding extremities 21
of the outer segment 19.

If the width W_3 is no less than the width W_1 (and
25 assuming that the width W_2 is less than either) cleats 10
may be mounted to be closely spaced or so that the lower
shoulders 33 of adjacent cleats 10 are in an abutting
relationship. Even when so mounted, cleats 10 will
nevertheless lend themselves to attachment to sole 47 by
30 bonding. When so attached, the bonding material is placed
to cover base plate 11 and extend outward through notches
61 to adhere to sole 47 in regions exterior to circular
path 57. This material will also flow into the aperture 29
and bond to the sole 47, thus further securing cleat 10.

35 When attaching cleat 10 to the sole 47, it is
preferred that the sole 47 be formed with shallow cavities
having a shape conforming to the perimeter outline of the

1 base plate 11 and a depth generally equal to its
thickness. The base plate 11 of a cleat 10 is placed into
each cavity prior to application of the bonding material.

To simplify the manufacturing function, it is
5 preferred that cleat 10 be formed to be useful on shoe
sizes ranging from about size 7 through about size 15.
Accordingly, a highly preferred embodiment of cleat 10 will
include an engagement member 15 having a curved surface 63
and an outer segment 19 which is similarly curved. The
10 curved edge of the outer segment 19 of the base plate 11
will be substantially coincident with a projected extension
of the engagement member 15.

Referring to FIGURE 5, the radius selected when
forming these parts 15, 19 is generally equal to the
15 distance from a central point 63 to circular path 57 on a
midrange shoe size, nominally a size 11 shoe. In addition,
the width W3 is selected in such a way that cleats 10
arranged in abutting relationship on the smallest shoe,
size 7, will define an acceptably smooth ring when cleats
20 10 are arranged in a generally circular path 57.

When using the inventive cleat 10, it is preferred
that the sole 47 of the shoe exhibit a high degree of
flexibility, particularly in those regions adjacent the
junction 65, 67 respectively of toe and ball-of-the-foot
25 portions 55, 53 and adjacent the ball-of-the-foot and the
arch portions 53, 51. It will be noted that each adjacent
pair of cleats 10 defines a generally V-shaped space 71
between them. To attain the desired flexibility, the cleats
10 are arranged so that a first opposed pair 73 of V-shaped
30 spaces 71 defines a break located adjacent the junction 67
of the arch portion 51 and the ball-of-the-foot portion
53. Similarly, a second opposed pair 75 of V-shaped spaces
75 defines a break located adjacent the junction 65 of the
ball-of-the-foot portion 53 and the toe portion 55. The
35 flexibility of the sole is thereby preserved. It is to be
understood that the V-shaped spaces 71 referred to are

-17-

1 defined by edges 37 of adjacent cleats 10 as would be seen
in a side elevation view of the sole of FIGURE 5.

From the foregoing, it will be understood that cleat
10 may be used in a number of patterns and for a wide range
5 of shoe sizes. This minimizes tooling costs and for a
given number of shoes to be fitted with cleats 10 it will
greatly increase the quantity of cleats 10 to be purchased
or manufactured. This will have very favorable
implications for the unit cost of each cleat 10.

10 In addition, inventory management will be greatly
simplified in that the same cleat 10 may be used to
assemble practically all sizes of shoes. This helps avoid
the necessity of segregating cleat sizes. In addition, it
dramatically reduces the chance of error on the part of a
15 shoe assembler who may otherwise use a cleat 10 of the
incorrect size.

Yet another benefit is that the inventive cleat 10
lends itself well to field replacement. A player or
athletic department wishing to effect cleat replacement
20 need only order a single cleat size.

Another benefit of inventive cleat 10 is that the
weight of the shoe may be reduced by fabricating cleat 10
of aluminum or plastic rather than of steel. When formed
of aluminum, cleat 10 may also be colored by anodizing and
25 this may provide certain marketing advantages. Weight
reduction may be especially important when a relatively
large numbers of cleats 10 are used on a shoe. In some
cases, it may be desirable to have, on a single shoe,
cleats of different materials; for example, cleats in
30 positions receiving more stress may be of one material,
while cleats in less-stressed positions may be of another.

While the principles of this invention have been
described in connection with specific embodiments, it
should be understood clearly that these descriptions are
made only by way of example and are not intended to limit
35 the scope of the invention.

1 CLAIMS:

5 1. A blade-like individual cleat for an athletic shoe comprising:

5 -a base plate for attachment to an athletic shoe sole, the base plate including an outer portion of first width and a tongue portion extending therefrom;
10 -a blade substantially normal to the base plate, the blade including a ground-engagement portion extending to a blade distal end and further including a support portion joining the ground-engagement portion to the base plate;

15 -the ground-engagement portion having opposed diverging edges extending from the blade distal end to shoulder extremities near the support portion; and
-the support portion having a width less than the first width to form a notch between the shoulder extremities and the base plate, thereby to facilitate cleat attachment to the sole,

20 whereby, when attached to the athletic shoe sole with a plurality of similar individual cleats arranged such that their ground-engagement portions extend along a circle, said cleat provides improved angular turf cutting and pivotability for said shoe.

25 2. The cleat of claim 1 wherein the ground-engagement portion of the blade forms a truncated isosceles triangle, thereby to provide further improved bidirectional pivotability.

30 3. The cleat of claim 1 wherein:

-the base plate outer portion has base extremities; and
-the shoulder extremities are vertically spaced from and aligned with the base extremities.

35

-19-

1 4. The cleat of claim 3 wherein the support portion
is substantially centered between the shoulder extremities,
thereby to form a pair of said notches at opposite ends of
the support portion.

5 5. The cleat of claim 1 wherein the
ground-engagement portion is arcuate.

10 6. The cleat of claim 1 wherein the tongue portion
extends to a tongue distal end which is narrower than the
first width, thereby facilitating close arrangement of a
plurality of such cleats in pie-piece arrangement.

15 7. A blade-like individual cleat for an athletic
shoe comprising:

 -a base plate for attachment to an athletic shoe
sole, the base plate including an outer portion of
first width and a tongue portion extending therefrom
to a terminal end, all of said tongue portion
configured to be coplanar with the sole;

20 -a blade substantially normal to the base plate, the
blade including a ground-engagement portion extending
to a blade distal end and further including a support
portion joining the ground-engagement portion to the
base plate; and

25 -the support portion having a width less than the
first width to form a substantially unobstructed
notch between the ground-engagement portion and the
base plate,

30 whereby the individual cleat may be more securely attached
to the sole.

35

1 8. A blade-like individual cleat for an athletic
shoe comprising:
 -a base plate for attachment to an athletic shoe
 sole, the base plate including an outer portion of
5 first width and a tongue portion extending therefrom;
 -a blade substantially normal to the base plate, the
 blade including a ground-engagement portion extending
 to a blade distal end and further including a support
10 portion joining the ground-engagement portion to the
 base plate; and
 -the ground-engagement portion having opposed
 diverging edges extending from the blade distal end
 to shoulder extremities near the support portion,
 whereby, when attached to the athletic shoe sole with a
15 plurality of similar individual cleats arranged such that
 their ground-engagement portions extend along a circle,
 said cleat provides improved angular turf cutting and
 pivotability for said shoe.

20 9. A blade-like individual cleat for an athletic
shoe comprising:
 -a base plate for attachment to an athletic shoe
 sole, the base plate including an outer portion of
 first width and a tongue portion extending therefrom;
25 -a blade substantially normal to the base plate, the
 blade including a ground-engagement portion extending
 to a blade distal end and further including a support
 portion joining the ground-engagement portion to the
 base plate; and
30 -the tongue portion extending to a tongue distal end
 which is narrower than the first width,
 thereby facilitating close arrangement of a plurality of
 such individual cleats in a pie-piece arrangement.

35

-21-

1 10. An athletic shoe sole having heel, arch,
ball-of-the-foot and toe portions and comprising:
 -a sole main portion;
 -an annular array of blade-like cleats disposed on
5 the sole main portion along a substantially circular path
which encompasses a major area of the ball-of-the-foot and
toe portions, each cleat including:
 -a base plate for attachment to the sole main
 portion, the base plate having an outer portion of
10 first width and a tongue portion extending therefrom;
 -a blade substantially normal to the base plate,
extending to a blade distal end, and substantially in
registry with said circular path, said blade having a
ground-engagement portion and a support portion
15 joining the ground-engagement portion to the base
plate;
 -the ground-engagement portion having opposed
diverging edges extending from the blade distal end
to shoulder extremities near the support portion; and
20 -the support portion having a width less than the
first width to form a notch between the shoulder
extremities and the base plate, thereby to facilitate
cleat attachment to the sole main portion,
whereby improved angular turf cutting and pivotability is
25 provided.

V. OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND UNSEARCHABLE¹

This international search report has not been established in respect of certain claims under Article 17(2) (a) for the following reasons:

1. Claim numbers _____, because they relate to subject matter¹ not required to be searched by this Authority, namely:

2. Claim numbers _____, because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out¹, specifically:

3. Claim numbers _____, because they are dependent claims not drafted in accordance with the second and third sentences of PCT Rule 6.4(a).

VI. OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING²

This International Searching Authority found multiple inventions in this international application as follows:

1. As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims of the international application.
2. As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims of the international application for which fees were paid, specifically claims:

3. No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claim numbers:

4. As all searchable claims could be searched without effort justifying an additional fee, the International Searching Authority did not invite payment of any additional fee.

Remark on Protest

- The additional search fees were accompanied by applicant's protest.
- No protest accompanied the payment of additional search fees.
