Abstract:

In a process for upgrading an ethane-containing C5 paraffin stream, the paraffin stream is contacted with an oxygen containing gas in the presence of a selective oxidation catalyst under conditions to selectively oxidize at least part of the ethane in the paraffin stream and produce a first product stream comprising ethylene. At least part of the first product stream is then with an oligomerization catalyst under conditions to oligomerize at least part of the ethylene and produce a second product stream comprising gasoline and/or distillate boiling range hydrocarbons. Gasoline and/or distillate boiling range hydrocarbons are then recovered from the second product stream and at least a part of any residual C5 paraffin stream is recycled to the selective oxidation step.

Title: UPGRADING ETHANE-CONTAINING LIGHT PARAFFINS STREAMS
UPGRADING ETHANE-CONTAINING LIGHT PARAFFINS STREAMS

FIELD
[0001] The present disclosure relates to upgrading ethane-containing light paraffin (C5-) streams, particularly natural gas liquid streams.

BACKGROUND
[0002] The supply of natural gas liquid (NGL) in North America has become abundant because of the shale gas boom. This provides an opportunity to use NGL as a low cost feedstock for the production of transportation fuels and chemicals. Greater supply of shale oil also poses a challenge in meeting gasoline octane requirements, since shale oil-sourced naphthas inherently have low octane values. Efficient conversion of NGL to high octane gasoline and/or high cetane diesel fuel can help alleviate these problems.
[0003] At present, commercially-proven processes for upgrading light paraffins are centered around dehydrogenation. For example, the C3 and C4 Oleflex™ processes, produce propylene and iso-butene by dehydrogenation of propane and iso-butane feedstock, respectively, in a series of radial flow reactors. In addition, the Cyclear™ process converts liquefied petroleum gas (LPG) directly into liquid aromatics by dehydrocyclodimerization, which involves the sequential dehydrogenation of C3 and/or C4 alkanes to olefins, oligomerization of the olefins, cyclization to naphthenes and dehydrogenation of naphthenes to corresponding aromatics.
[0004] However, these processes have so far only been used for generating higher value chemical feedstocks because of the high capital and operating costs involved. In addition, they do not address the oversupply of ethane. There is therefore a need to develop a cost effective process for converting ethane in mixed light paraffin (C5-) streams to liquid fuels.
[0005] An alternative process for converting alkanes to alkenes is by selective oxidation, in which the alkane is catalytically dehydrogenated in the presence of oxygen. The process is also called oxidative dehydrogenation (ODH) and can be carried out at lower reaction temperatures than reductive dehydrogenation processes discussed above, and without the same problem of coke formation. For example, US Patent No. 8,519,210 discloses a process for the oxidative dehydrogenation of gaseous hydrocarbons, particularly ethane, to olefins, particularly ethylene. The process comprises contacting an ethane feed and an oxygen-containing gas in the presence of at least one of water and steam and an oxidative dehydrogenation catalyst comprising MoaVbNbcYdTeeOn wherein Y=Sb or Ni; a=1.0; b=0.05 to 1.0; c=0.001 to 1.0; d=0.001 to 1.0; e=0.001 to 0.5; and n is determined by the oxidation states of the other elements.
[0006] It is also known from, for example, US Patent Nos. 7,807,601 and 7,910,772, that light alkanes, especially propane can be selectively oxidized into unsaturated carboxylic acids,
such as acrylic acid, in the presence of mixed-metal oxide catalysts having the formula MoaVbNbcTedSbeOf wherein, when a=1, b=0.01 to 1.0, c=0.01 to 1.0, d=0.01 to 1.0, e=0.01 to 1.0, and f is dependent upon the oxidation state of the other elements.

[0008] However, although the selective oxidation of light alkanes has been extensively studied, the focus of the studies has been on the production of chemicals and chemical intermediates and, as reported in the Cavani et al. article, significant commercial utility has yet to be demonstrated.

SUMMARY

[0009] According to the present disclosure, it has now been appreciated that the combination of selective oxidation with oligomerization of the resultant olefins can be used to upgrade ethane-containing light paraffin (C5-) streams, particularly natural gas liquid streams, to high octane gasoline and/or high cetane distillate. Such a combination achieves the joint goals of providing an economically attractive route for utilization of the increasing supply of natural gas liquid and addressing the lower octane and cetane values inherent in the increased use of shale oils as gasoline and distillate components.

[0010] Thus, in one aspect, the present disclosure resides in a process for upgrading an ethane-containing C5- paraffin stream, the process comprising:

(a) contacting the paraffin stream with an oxygen containing gas in the presence of a selective oxidation catalyst under conditions to selectively oxidize at least part of the ethane in the paraffin stream and produce a first product stream comprising ethylene; and

(b) contacting at least part of the first product stream with at least one oligomerization catalyst under conditions to oligomerize at least part of the ethylene and produce a second product stream comprising gasoline and/or distillate boiling range hydrocarbons; and

(c) recovering gasoline and/or distillate boiling range hydrocarbons from the second product stream and recycling at least a part of the residual C5- paraffin stream to the contacting (a).

DETAILED DESCRIPTION

[0011] For the purpose of this description and appended claims, the following terms are defined. The term "C_n" hydrocarbon wherein n is a positive integer, e.g., 1, 2, 3, 4, or 5, means a hydrocarbon having n number of carbon atom(s) per molecule. The term "C_n+" hydrocarbon
wherein \( n \) is a positive integer, e.g., 1, 2, 3, 4, or 5, means a hydrocarbon having at least \( n \) number of carbon atom(s) per molecule. The term "\( \text{C}_n \)" hydrocarbon wherein \( n \) is a positive integer, e.g., 1, 2, 3, 4, or 5, means a hydrocarbon having no more than \( n \) number of carbon atom(s) per molecule. The term "hydrocarbon" encompasses mixtures of hydrocarbon having different values of \( n \). As used herein, the numbering scheme for the groups of the Periodic Table of the Elements is as disclosed in Chemical and Engineering News, 63(5), 27 (1985).

[0012] Described herein is a multi-step process for upgrading an ethane-containing light paraffin (C5-) stream, particularly a natural gas liquid stream or fraction thereof, to gasoline and/or distillate boiling range hydrocarbons. As a first step, the ethane-containing light paraffin (C5-) stream is reacted with an oxygen containing gas in the presence of a selective oxidation catalyst under conditions to convert at least part of the ethane to ethylene. At least part of the resultant ethylene is then oligomarized in a single stage or in multiple stages to produce the desired gasoline and/or distillate boiling range hydrocarbons. Residual C5- paraffins can be separated from the selective oxidation effluent and/or the oligomerization effluent and recycled back to the selective oxidation step.

Feedstock

[0013] The present process can be used to upgrade any ethane-containing light paraffin (C5-) feedstock, but is particularly effective for upgrading natural gas liquid (NGL) streams and fractions thereof. NGL is a mixture of ethane and lesser quantities of propane, butanes and pentanes remaining after demethanization of natural gas. In most cases, the as-produced natural gas is initially subjected to multiple pretreatment steps to remove condensate, water, nitrogen and reactive gaseous impurities, such as hydrogen sulfide and carbon oxides, before being fed to the demethanizer. In addition, before being used in the present process, the NGL can be treated, for example by fractionation, to remove part or all of the C3+ hydrocarbons.

[0014] Preferred ethane-containing light paraffin (C5-) streams useful in the present process contain at least 80 wt%, such as at least 85 wt%, for example at least 90 wt%, such as at least 95 wt%, even up to 100 wt%, ethane; less than 20 wt %, such as less than 15 wt%, for example less than 10 wt%, such as less than 5 wt % methane and/or less than 20 wt %, such as less than 15 wt%, for example less than 10 wt%, such as less than 5 wt % propane. To avoid excessive separation costs, most light paraffin streams employed in the present process will contain at least 0.5 wt% methane and/or at least 0.5 wt% propane.

Ethane Oxydehydrogenation

[0015] Any catalyst effective for the oxydehydrogenation of ethane in a C5- mixed paraffin stream to produce ethylene can be used in the present process. The effectiveness of the catalyst
is usually primarily determined by two parameters: the activity of the catalyst for ethane conversion, and selectivity (efficiency) of the conversion to ethylene rather than acetic acid. Suitable oxydehydrogenation catalysts with a desirable combination of activity and selectivity are frequently mixed metal oxides, especially mixed oxides of molybdenum and vanadium, optionally with one or more other metal oxides. One such preferred oxide is niobium oxide.

For example, the article entitled "The Oxidative Dehydrogenation of Ethane over Catalyst Containing Mixed Oxide of Molybdenum and Vanadium" by E. M. Thorsteinson, T. P. Wilson, F. G. Young and P. H. Kasai, Journal of Catalysis 52, pp. 116-132 (1978) discloses that mixed oxide catalysts containing molybdenum and vanadium together with another transition metal oxide (Ti, Cr, Mn, Fe, Co, Ni, Nb, Ta, or Ce) are active at temperatures as low as 200° C for the oxydehydrogenation of ethane to ethylene.

U.S. Patent No. 4,250,346, the entire contents of which are incorporated herein by reference, discloses catalytic oxydehydrogenation of ethane to ethylene at temperatures less than 550° C, in which the catalyst is a calcined composition comprising the elements Mo, X, and Y in the ratio:

\[
\text{Mo}_a \text{X}_b \text{Y}_c
\]

wherein: \(X=\text{Cr}, \text{Mn}, \text{Nb}, \text{Ta}, \text{Ti}, \text{V}, \text{and/or W}; Y=\text{Bi}, \text{Ce}, \text{Co}, \text{Cu}, \text{Fe}, \text{K}, \text{Mg}, \text{Ni}, \text{P}, \text{Pb}, \text{Sb}, \text{Si}, \text{Sn}, \text{Ti}, \text{and/or U}; a=1; b=0.05 \text{ to } 1.0 \text{ and } c=0 \text{ to } 2.\)

U.S. Patent No. 4,568,790, the entire contents of which are incorporated herein by reference, discloses process for converting ethane to ethylene by catalytically oxydehydrogenating ethane exothermically at a temperature of less than 450° C in the gas phase using a calcined catalyst containing:

\[
\text{Mo}_a \text{V}_b \text{Nb}_c \text{Sb}_d
\]

wherein \(a=0.5 \text{ to } 0.9, b=0.1 \text{ to } 0.4, c=0.001 \text{ to } 0.2 \text{ and } d=0.001 \text{ to } 0.1.\)

U.S. Patent No. 7,910,772, the entire contents of which are incorporated herein by reference, discloses a catalyst for the oxidation of an alkane, alkene or mixtures thereof and including a mixed-metal oxide having the formula \(\text{Mo}_a \text{V}_b \text{Nb}_c \text{TedSb}_f\) whereby, when \(a=1, b=0.01 \text{ to } 1.0, c=0.01 \text{ to } 1.0, d=0.01 \text{ to } 1.0, e=0.01 \text{ to } 1.0, \text{ and } f \text{ is dependent upon the oxidation state of the other elements, the catalyst further characterized by having at least two crystal phases, the first crystal phase being an orthorhombic M1 phase and the second crystal phase being a pseudo-hexagonal M2 phase, the orthorhombic M1 phase present in an amount between greater than 60 weight percent to less than 90 weight percent.}

a catalyst for the oxidative dehydrogenation of ethane, with a relatively high yield to ethylene reporting selectivity to ethylene higher than 90% with productivity in the range 2,500 g ethylene per hour and kg of catalyst. The catalyst employed is a tellurium-containing solid with as general formula VxMo\textsubscript{H}VbTe\textsubscript{M}MenOp, wherein Me is a metal belonging to the group Ta, Ti, W, Hf, Zr and Sb, or a mixture of them. The entire contents of these patent documents are incorporated herein by reference.

[0021] U.S. Patent Application Publication No. 2010/0256432A1, assigned to Lummus Novolent GMBH/Lummus Technology Inc., and U.S. Patent No. 8,105,971 B2 assigned to Lummus Technology Inc., disclose a high performance catalyst for the oxidative dehydrogenation of ethane to ethylene. Over this catalytic system represented by Mo.xVb.29Nbo.17Sb0.25Te0.1250x, ethane conversion reportedly reach values of up to 81% with an ethylene selectivity of 89% when reaction is conducted at 360° C. The entire contents of these patent documents are incorporated herein by reference.

[0022] U.S. Patent No. 9,409,156, the entire contents of which are incorporated herein by reference, discloses the oxidative dehydrogenation of light paraffins, such as ethane, at moderate temperatures (<500° C) to produce ethylene without the formation of side products, such as acetic acid and/or other oxygenated hydrocarbons, using a tellurium-free, multimetallic catalyst possessing orthorhombic M1 phase having the formula:

\[
\text{MoVhSb}_x\text{A}_y\text{O}_z
\]

wherein A represents Nb, W, Ga, Bi, Sn, Cu, Ti, Fe, Co, Ni, Cr, Zr, rare earth metals or rare earth alkaline metals or mixtures of thereof, h and i, respectively, are each between 0.001 and 4.0, 0≤j≤2.0, the ratio i/h is between 0.3 and 10.0, and x represents the number determined by and consistent with the valence requirements of the other elements present in the multimetallic mixed oxide.

[0023] Any or all of the above mixed metal oxide catalyst compositions may be used in the ethane oxidative dehydrogenation step of the present process.

[0024] The mixed metal oxide catalyst is preferably prepared from a solution of soluble compounds (salts, complexes or other compounds) of each of the desired elements. The solution is preferably an aqueous system having a pH of 1 to 7, and preferably 2 to 6. The solution of the element containing compounds is prepared by dissolving sufficient quantities of soluble compounds of each of the elements, so as to provide the desired gram-atom ratios of the elements. To the extent possible the selected compounds of the various elements should be mutually soluble. Where any of the selected compounds of such elements are not mutually soluble with the other compounds, they can be added last to the solution system. The catalyst
composition is then prepared by removing the water or other solvent from the mixture of the compounds in the solution system, such as by evaporation. The dried mixture may then be calcined by being heated at about 220 to 550°C in air or oxygen for 1/2 to 24 hours to produce the final catalyst.

[0025] The mixed metal oxide catalyst can be used with or without a support. Suitable supports include silica, aluminum oxide, silicon carbide, zirconia, titania and mixtures thereof. When used on a support, the supported catalyst usually comprises about 10 to 50 weight % of the mixed metal oxide catalyst composition, with the remainder being the support.

[0026] Where the catalyst is to be used on a support, the compounds of the desired elements are deposited on a particulate porous support by immersing the support individually or collectively in a solution of each of the compounds, evaporating off the major portion of the solvent, and then drying the system at about 80 to 220°C for 2 to 60 hours. Again the dried composition may then be calcined by being heated at about 220 to 550°C in air or oxygen for 1/2 to 24 hours to produce the final catalyst.

[0027] In some cases, it may be desirable that one or more of the metal components in the mixed metal oxide catalyst should be slightly reduced below its highest possible oxidation state. This may be accomplished by thermal treatment of the catalyst in the presence of reducing agents such as NH₃ or organic reducing agents, such as the organic complexing agents, which are introduced into the solution systems from which the catalysts are prepared. The catalyst may also be reduced in the reactors in which the oxidation reaction is to be conducted by the passage of hydrogen or hydrocarbon reducing agents such as ethane, ethylene, or propylene through the catalyst bed.

[0028] The oxydehydrogenation reaction is conducted by contacting the ethane-containing light paraffin (C₅-) with any oxygen containing gas, such as air, in the presence of one or more mixed metal oxide catalysts as described above under conditions effective to selectively oxidize at least part of the ethane to produce ethylene. Suitable conditions include a temperature from 200 °C to 700 °C, such as from 300 to 550°C and a pressure from 100 kPa-a to 6895 kPa-a, such as from 100 to 5000 kPa-a. The reaction can be conducted in any suitable reactor, such as a fixed bed reactor or fluidized bed reactor.

[0029] The amount of oxygen added to the light paraffin (C₅-) feed is not critical but generally is selected such that the total feed to the oxydehydrogenation reaction is from 0.01 to 0.7 mole, such as from 0.1 to 0.6 mole of molecular oxygen (as pure oxygen or in the form of air) per mole of ethane in the feed. Since the reaction is exothermic, diluents can also be supplied to
the reaction to moderate heat generation. Suitable diluents include water, nitrogen, helium, \textbf{CO2}, and methane. It will be appreciated that water is an inherent by-product of the reaction.

[0030] By suitable selection of the catalyst and the reaction conditions, the oxidative dehydrogenation step can be conducted so as to selectively convert at least 50\%, such as at least 60\%, such as at least 70\%, such as at least 80\%, even as much as 90\%, of the ethane in the feed to ethylene. Similarly, any propane and/or butane in the feed will be at least partly converted to propylene and butenes.

[0031] In addition to \textit{C2+} olefins and co-produced water, the product of the oxidative dehydrogenation step may contain various organic oxygenates, for example carboxylic acids, such as acetic acid and acrylic acid; alcohols such as methanol and ethanol; aldehydes, such as formaldehyde, acetaldehyde, propionaldehyde, and acrylic aldehyde; esters, such as ethyl acetate and propane acetate and ketones, such as acetone. The product may also contain unreacted \textit{C5+} hydrocarbons, as well as inert impurities present in the initial feedstock, such as \textbf{N2} and \textbf{CO2}.

[0032] The product of the oxidative dehydrogenation step may be fed to the next stage in the process, namely ethylene oligomerization, without intermediate separation or may initially be subjected to one or more separation steps, for example, to remove unreacted \textit{C5+} hydrocarbons for recycle to the dehydrogenation step or to recover valuable organic oxygenates, such as acetic acid and acrylic acid. Generally, however, intermediate separation is avoided since propene and higher olefins as well as many organic oxygenates can be converted to gasoline and/or distillate boiling range hydrocarbons in the oligomerization process.

\textbf{Ethylene Oligomerization}

[0033] Oligomerization of at least part of the ethylene component in the oxidative dehydrogenation effluent to produce gasoline and/or distillate boiling range hydrocarbons may be achieved by contacting the ethylene with one or more oligomerization catalysts in one or multiple stages.

[0034] In one embodiment, the oligomerization catalyst employed in at least one oligomerization stage comprises at least one medium pore molecular sieve having a Constraint Index of 2-12 (as defined in U.S. Patent No. 4,016,218). Suitable medium pore molecular sieves include ZSM-5, ZSM-11, ZSM-12, ZSM-22, ZSM-23, ZSM-35, and ZSM-48. ZSM-5 is described in detail in U.S. Patent Nos. 3,702,886 and Re. 29,948. ZSM-11 is described in detail in U.S. Patent No. 3,709,979. ZSM-12 is described in U.S. Patent No. 3,832,449. ZSM-22 is described in U.S. Patent No. 4,556,477. ZSM-23 is described in U.S. Patent No. 4,076,842. ZSM-35 is described in U.S. Patent No. 4,016,245. ZSM-48 is more particularly described in U.S. Patent No. 4,234,231.
Other suitable oligomerization catalysts comprise one or more large pore molecular sieves having a Constraint Index less than 2. Suitable large pore molecular sieves include zeolite beta, zeolite Y, Ultrastable Y (USY), Ultrahydrophobic Y (UHP-Y), Dealuminized Y (Deal Y), mordenite, ZSM-3, ZSM-4, ZSM-14, ZSM-18, ZSM-20 and mixtures thereof. Zeolite ZSM-3 is described in U.S. Patent No. 3,415,736. Zeolite ZSM-4 is described in U.S. Patent No. 4,021,947. Zeolite ZSM-14 is described in U.S. Patent No. 3,923,636. Zeolite ZSM-18 is described in U.S. Patent No. 3,950,496. Zeolite ZSM-20 is described in U.S. Patent No. 3,972,983. Zeolite Beta is described in U.S. Patent Nos. 3,308,069, and Re. No. 28,341. Low sodium Ultrastable Y molecular sieves (USY) is described in U.S. Patent Nos. 3,293,192 and 3,449,070. Ultrahydrophobic Y (UHP-Y) is described in U.S. Patent No. 4,401,556. Dealuminized Y zeolite (Deal Y) may be prepared by the method found in U.S. Patent No. 3,442,795. Zeolite Y and mordenite are naturally occurring materials but are also available in synthetic forms, such as TEA-mordenite (i.e., synthetic mordenite prepared from a reaction mixture comprising a tetraethylammonium directing agent). TEA-mordenite is disclosed in U.S. Patent Nos. 3,766,093 and 3,894,104.

Other suitable oligomerization catalysts comprise at least one molecular sieve of the MCM-22 family. As used herein, the term "molecular sieve of the MCM-22 family" (or "material of the MCM-22 family" or "MCM-22 family material" or "MCM-22 family zeolite") includes one or more of:

- molecular sieves made from a common first degree crystalline building block unit cell, which unit cell has the MWW framework topology. (A unit cell is a spatial arrangement of atoms which if tiled in three-dimensional space describes the crystal structure. Such crystal structures are discussed in the "Atlas of Zeolite Framework Types", Fifth edition, 2001, the entire content of which is incorporated as reference);

- molecular sieves made from a common second degree building block, being a 2-dimensional tiling of such MWW framework topology unit cells, forming a monolayer of one unit cell thickness, preferably one c-unit cell thickness;

- molecular sieves made from common second degree building blocks, being layers of one or more than one unit cell thickness, wherein the layer of more than one unit cell thickness is made from stacking, packing, or binding at least two monolayers of one unit cell thickness. The stacking of such second degree building blocks can be in a regular fashion, an irregular fashion, a random fashion, or any combination thereof; and
• molecular sieves made by any regular or random 2-dimensional or 3-dimensional combination of unit cells having the MWW framework topology.

[0037] Molecular sieves of the MCM-22 family include those molecular sieves having an X-ray diffraction pattern including d-spacing maxima at 12.4±0.25, 6.9±0.15, 3.57±0.07 and 3.42±0.07 Angstrom. The X-ray diffraction data used to characterize the material are obtained by standard techniques using the K-alpha doublet of copper as incident radiation and a diffractometer equipped with a scintillation counter and associated computer as the collection system.

[0039] Generally, the molecular sieves described above are employed in the oligomerization catalyst as an aluminosilicate material having a silica to alumina molar ratio of at least 10, such as at least 25 to 100.

[0040] Preferred molecular sieves for use in the oligomerization reaction are those having a Constraint Index of 2-12 as described above, especially ZSM-5 and more particularly ZSM-5 having a homogeneous crystal size of <0.05 micron and a relatively high activity (alumina content) characterized by a SiO2/Al2O3 molar ratio of around 50:1 or less.

[0041] The above molecular sieves may be employed in their acid forms, ion exchanged or impregnated with one or more suitable metals, such as Ga, Pd, Zn, Ni, Co and/or other metals of Periodic Groups 3 to 14. The molecular sieve may include a hydrogenation-dehydrogenation component (sometimes referred to as a hydrogenation component) which is generally one or more metals of Groups 5, 6 and 8 to 13 of the Periodic Table, especially aromatization metals such as Ga, Pd, etc. Useful hydrogenation components include the noble metals of Groups 9 to 11, especially platinum, gold, silver, rhenium, and rhodium. The catalyst material may include two or more catalytic components, such as metallic oligomerization component (e.g., ionic Ni and a shape-selective medium pore acidic oligomerization catalyst, such as ZSM-5 zeolite) which components may be present in admixture or combined in a unitary bifunctional solid particle.
The above molecular sieves may be used as the oligomerization catalyst without any binder or matrix, i.e., in so-called self-bound form. Alternatively, the molecular sieve may be compositized with another material which is resistant to the temperatures and other conditions employed in the oligomerization reaction. Such materials include active and inactive materials and synthetic or naturally occurring zeolites as well as inorganic materials such as clays and/or oxides such as alumina, silica, silica-alumina, zirconia, titania, magnesia or mixtures of these and other oxides. The latter may be either naturally occurring or in the form of gelatinous precipitates or gels including mixtures of silica and metal oxides. Clays may also be included with the oxide type binders to modify the mechanical properties of the catalyst or to assist in its manufacture. Use of a material in conjunction with the molecular sieve, i.e., combined therewith or present during its synthesis, which itself is catalytically active may change the conversion and/or selectivity of the catalyst. Inactive materials suitably serve as diluents to control the amount of conversion so that products may be obtained economically and orderly without employing other means for controlling the rate of reaction. These materials may be incorporated into naturally occurring clays, e.g., bentonite and kaolin, to improve the crush strength of the catalyst under commercial operating conditions and function as binders or matrices for the catalyst. The relative proportions of molecular sieve and inorganic oxide matrix vary widely, with the sieve content ranging from about 1 to about 90 percent by weight and more usually, particularly, when the composite is prepared in the form of beads, in the range of about 2 to about 80 weight percent of the composite.

Oligomerization over the molecular sieves described above may be conducted over a wide range of temperatures and pressures, for example at temperatures from about 20°C to 300°C (preferably 50°C to 200°C) and pressures from ambient to about 5500 kPa (preferably about 250 to 2900 kPa). Within these ranges, higher severity conditions generally favor ethylene conversion and the production of gasoline (Cs-Cio) boiling-range products, whereas less severe conditions favor production of heavier distillate boiling-range products at the expense of ethylene conversion activity. Thus, in some embodiments, the oligomerization may be conducted in two or more stages, with one stage being conducted at higher severity conditions to produce olefinic gasoline and part or all of the gasoline being fed to a later oligomerization stage to produce distillate.

In some embodiments, the oligomerization over the molecular sieves described above may be preceded by, or occur simultaneously with, an ethylene dimerization step, in which part or all of the oxidative dehydrogenation product is contacted with a metal dimerization catalyst under conditions effective to convert ethylene to C4+ olefins, especially 1-butene. In this respect,
the term "dimerization" is used in the present specification to mean a specific case of oligomerization so that the broader term "oligomerization" is intended to include dimerization. The term oligomerization is also intended to processes in which the oligomerization is accompanied by cyclization to produce aromatic and non-aromatic cyclic olefins as well as non-cyclic linear or branched C4+ olefins.

[0045] Suitable ethylene dimerization catalysts comprise one or more metals or compounds thereof selected from the group consisting of nickel, manganese, iron and copper deposited on a suitable support, such as silica. Where ethylene dimerization occurs simultaneously with oligomerization, the support may be one or more of the molecular sieves described above, especially ZSM-5.

[0046] Other suitable ethylene dimerization/oligomerization catalysts include mixed metal oxides containing, such as, as an oxide of a Group 4 metal, for example, Zr, and oxide of a Group 6 metal, such as W, optionally together with one or more oxides of Group 7 to 11 metals, such as Fe, Cu, Mn and Ce. A description of the production of such mixed metal oxides and their use in olefin oligomerization can be found in U.S. Patent No. 5,608,133, the entire contents of which are incorporated herein by reference.

[0047] The oligomerization reaction can be conducted in any suitable reactor or series of reactors, including one or more fixed bed reactors, moving bed reactors and/or fluidized bed reactors.

[0048] Depending on the catalyst(s) and the reaction conditions employed, the effluent from the oligomerization reaction will contain gasoline and/or distillate boiling range hydrocarbons, together with unreacted ethylene and/or C4+ olefins and potentially water, unreacted C5+ hydrocarbons, organic oxygenates from the oxidative dehydrogenation reaction. In any event, the oligomerization effluent can be fed to a separation system, such as a distillation train, where gasoline and/or distillate boiling range hydrocarbons may be recovered, while the unreacted ethylene and/or C4+ olefins can be separated for recycle to the oligomerization step, and unreacted C5+ paraffins can be separated for recycle to the oxidative dehydrogenation step.

[0049] In some embodiments, isoparaffins and aromatic compounds can be cofed with the C2+ olefins to the oligomerization reactor(s) so that some of the ethylene and, if present, propene and butenes, can react with the isoparaffin to generate alkylate, or can alkylate benzene to generate high octane product and also chemicals. In the case of cofeeding isoparaffins, the presence of propene/butenes in the feed is particularly advantageous in that it speeds up alkylation of the isoparaffins with the ethylene.
While the present invention has been described and illustrated by reference to particular embodiments, those of ordinary skill in the art will appreciate that the invention lends itself to variations not necessarily illustrated herein. For this reason, then, reference should be made solely to the appended claims for purposes of determining the true scope of the present invention.
CLAIMS:
1. A process for upgrading an ethane-containing C5 paraffin stream, the process comprising:
   (a) contacting the paraffin stream with an oxygen containing gas in the presence of a
   selective oxidation catalyst under conditions to selectively oxidize at least part of the ethane in
   the paraffin stream and produce a first product stream comprising ethylene; and
   (b) contacting at least part of the first product stream with at least one oligomerization
   catalyst under conditions to oligomerize at least part of the ethylene and produce a second
   product stream comprising gasoline and/or distillate boiling range hydrocarbons; and
   (c) recovering gasoline and/or distillate boiling range hydrocarbons from the second
   product stream and recycling at least a part of the residual C5 paraffin stream to the contacting
   (a).
2. The process of claim 1, wherein the paraffin stream comprises ethane and propane.
3. The process of claim 1, wherein the paraffin stream comprises a natural gas liquid
   containing less than 20 wt % methane.
4. The process of claim 1, where the paraffin stream comprises less than 20wt% propane.
5. The process of claim 1, wherein the selective oxidation catalyst comprises a mixed metal
   oxide.
6. The process of claim 5, wherein the mixed metal oxide comprises oxides of molybdenum
   and vanadium.
7. The process of claim 6, wherein the mixed metal oxide further comprise an oxide of
   niobium.
8. The process of claim 1, wherein the conditions in the contacting (a) include a temperature
   from 200 °C to 700 °C and a pressure from 100 kPa-a to 6895 kPa-a.
9. The process of claim 1, wherein at least 50% of the ethane selectively oxidized in the
   contacting (a) is converted to ethylene.
10. The process of claim 1, wherein the first product stream is supplied to the contacting (b)
    without intermediate separation.
11. The process of claim 10, wherein the first product stream comprises one or more
    oxygenates selected from carboxylic acids and esters thereof, alcohols, aldehydes, ketones and
    mixtures thereof.
12. The process of claim 1, wherein the oligomerization catalyst comprises a molecular sieve.
13. The process of claim 12, wherein the molecular sieve has a Constraint Index of 1-12.
14. The process of claim 12, wherein the molecular sieve is selected from the group
15. The process of claim 12, wherein the molecular sieve comprise ZSM-5.
16. The process of claim 12, wherein the oligomerization catalyst further comprises a hydrogenation-dehydrogenation component.
17. The process of claim 16, wherein the hydrogenation-dehydrogenation component comprises at least one of Ga, Pt, Pd, Zn, Ni, and Co or a compound thereof.
18. The process of claim 1, wherein the oligomerization catalyst comprises a mixed metal oxide.
19. The process of claim 18, wherein the mixed metal oxide comprises oxides of zirconium and tungsten.
20. The process of claim 1, wherein the conditions in the contacting (b) include a temperature from 300°C to 550°C and a pressure from 100 kPa-a to 5000 kPa-a.
### INTERNATIONAL SEARCH REPORT

**International application No**  
PCT/US2017/065008

**A. CLASSIFICATION OF SUBJECT MATTER**

<table>
<thead>
<tr>
<th>INV.</th>
<th>C10G27/04</th>
<th>C07C2/12</th>
<th>C07C5/48</th>
<th>C10G57/02</th>
</tr>
</thead>
</table>

According to International Patent Classification (IPC) or to both national classification and IPC.

**B. FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols):

<table>
<thead>
<tr>
<th>Category</th>
<th>Citation</th>
<th>Relevance to claim No.</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>US 2007/249793 AI (VANDERBIJLT JEFFREY J [US] ET AL) 25 October 2007 (2007-10-25) paragraphs [0007], [0030], [0031], [0054], [0056]; claims 1,12; examples 1-5</td>
<td>1,3-5,8, 10</td>
</tr>
</tbody>
</table>

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched.

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

EPO-Internal

**C. DOCUMENTS CONSIDERED TO BE RELEVANT**

<table>
<thead>
<tr>

</table>

Further documents are listed in the continuation of Box C.

See patent family annex.

*S* Special categories of cited documents:

- **"A"** document defining the general state of the art which is not considered to be of particular relevance.
- **"E"** earlier application or patent but published on or after the international filing date.
- **"L"** document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified).
- **"O"** document referring to an oral disclosure, use, exhibition or other means.
- **"P"** document published prior to the international filing date but later than the priority date claimed.
- **"T"** later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention.
- **"X"** document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone.
- **"Y"** document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- **"A"** document member of the same patent family.

**Date of the actual completion of the international search**  
22 February 2018

**Date of mailing of the international search report**  
28/02/2018
