BIARYL SULFONAMIDES AS MMP INHIBITORS

FIELD OF THE INVENTION

The present invention relates to biaryl sulfonamides and their use as, for example, metalloproteinase inhibitors.

BACKGROUND OF THE INVENTION

Metalloproteinases, including matrix metalloproteinases and aggrecanases, are known to have a role in the breakdown of connective tissue. Matrix metalloproteinases ("MMPs") constitute a superfamily of proteolytic enzymes that are genetically related and capable of degrading almost all the constituents of extracellular matrix and basement membrane that restrict cell movement. Aggrecanases, members of the ADAMTS (A disintegrin and metalloproteinase with thrombospondin motifs) family of proteins, cleave aggrecan, a cartilage component also known as the large aggregating chondroitin sulphate proteoglycan.

MMPs and aggrecanases can degrade various components of connective tissue, including collagen and proteoglycan. In the absence of natural checks on this activity, a variety of pathologies and undesirable effects can occur. In fact, MMPs and aggrecanases are known to play a role in many disorders in which extracellular protein degradation/destruction occurs, such as cancer, osteoarthritis, rheumatoid arthritis, asthma, chronic obstructive pulmonary disease ("COPD"), atherosclerosis, age-related macular degeneration, myocardial infarction, corneal ulceration and other ocular surface diseases, hepatitis, aortic aneurysms, tendinitis, central nervous system diseases, abnormal wound healing, angiogenesis, restenosis, cirrhosis, multiple sclerosis, glomerulonephritis, graft versus host disease, diabetes, inflammatory bowel disease, shock, invertebral disc degeneration, stroke, osteopenia, and periodontal diseases.
Therefore, metalloproteinase inhibitors are needed, including inhibitors of MMPs and aggreganases. Additionally, selective inhibitors directed to specific MMPs and aggreganases are valuable to avoid potential side effects.

**SUMMARY OF THE INVENTION**

In one embodiment, the present invention provides novel biaryl sulfonamide compounds. Preferred compounds of the invention are those of the formula 1:

![Chemical Structure](image)

wherein:
- $R^1$ and $R^2$ are, independently, H, CH(OH)R$^4$, phenyl, heteroaryl, or C1-C6 alkyl, with the proviso that when $R^1$ or $R^2$ is CH(OH)R$^4$, then Z is substituted with NR$^5$SO$_2$R$^5$, SO$_2$NR$^5$R$^5$, heterocycloalkyl, heteroaryl, or C3-C6 cycloalkyl;
- $R^3$ is H or C1-C6 alkyl;

In another aspect, the present invention provides methods for using biaryl sulfonamide compounds to modulate and, preferably, inhibit metalloproteinases. Preferred methods involve in vitro and in vivo contacting of the metalloproteinase with a biaryl sulfonamide. Preferred methods of this type are ones in which the activity of the metalloproteinase is determined before or after such contacting and, optionally, the determination is used to assess the extent to which the compound modulates the activity of the enzyme.
DETAILED DESCRIPTION OF THE INVENTION

In accordance with the present invention it has been discovered that biaryl sulfonamide compounds of the present invention are useful in inhibiting metalloproteinases. Moreover, some compounds show great specificity for certain metalloproteinases. Such compounds can be useful in the treatment of cancer, osteoarthritis, rheumatoid arthritis, asthma, COPD, atherosclerosis, age-related macular degeneration, myocardial infarction, corneal ulceration and other ocular surface diseases, hepatitis, aortic aneurysms, tendonitis, central nervous system diseases, abnormal wound healing, angiogenesis, restenosis, cirrhosis, multiple sclerosis, glomerulonephritis, graft versus host disease, diabetes, inflammatory bowel disease, shock, intervertebral disc degeneration, stroke, osteopenia, and periodontal diseases. The metalloproteinase is preferably, Gelatinase A (MMP-2), Macrophage metalloelastase (MMP-12), Collagenase-3 (MMP-13), or Aggrecanase-1 (ADAMTS4). More preferably, the metalloproteinase is MMP-13.

The term "alkyl", as used herein, whether used alone or as part of another group, refers to a substituted or unsubstituted aliphatic hydrocarbon chain and includes, but is not limited to, straight and branched chains containing from 1 to 12 carbon atoms, preferably 1 to 6 carbon atoms, unless explicitly specified otherwise. For example, methyl, ethyl, propyl, isopropyl, butyl, i-butyl and t-butyl are encompassed by the term "alkyl." C1-C6 alkyl includes straight and branched chain aliphatic groups having from 1 to 6 carbons. Specifically included within the definition of "alkyl" are those aliphatic hydrocarbon chains that are optionally substituted.

The carbon number as used in the definitions herein refers to carbon backbone and carbon branching, but does not include carbon atoms of the substituents, such as alkoxy substitutions and the like.

The term "alkenyl", as used herein, whether used alone or as part of another group, refers to a substituted or unsubstituted hydrocarbon chain and includes, but is not limited to, straight and branched chains having 2 to 8 carbon atoms and containing at least one double bond. Preferably, the alkenyl moiety has 1 or 2 double bonds. Such alkenyl moieties may exist in the E or Z conformations and the compounds of this invention include both conformations. C2-C6 alkenyl includes a 1 to 6 carbon straight or branched chain having at least one carbon-carbon double bond. Specifically included within the definition of "alkenyl" are those aliphatic
hydrocarbon chains that are optionally substituted. Heteroatoms, such as O, S or NR^4R^5, attached to an alkenyl should not be attached to a carbon atom that is bonded to a double bond.

The term "alkynyl" refers to a hydrocarbon moiety containing at least one carbon-carbon triple bond. C2-C6 alkyne includes a 2 to 6 carbon straight or branched chain having at least one carbon-carbon triple bond.

The term "cycloalkyl" refers to a monocyclic, bicyclic, tricyclic, fused, bridged, or spiro monovalent saturated hydrocarbon moiety, wherein the carbon atoms are located inside or outside of the ring system. Any suitable ring position of the cycloalkyl moiety may be covalently linked to the defined chemical structure. Examples of cycloalkyl moieties include, but are not limited to, chemical groups such as cyclopropyl, cyclopropylmethyl, cyclobutyl, cyclopentyl, cyclohexyl, cyclohexylmethyl, cyclohexylethyl, cycloheptyl, norbornyl, adamantyl, spiro[4.5]decanyl, and homologs, isomers, and the like. C3-C6 cycloalkyl includes monocyclic, saturated rings of 3 to 6 carbons, optionally substituted with R^6.

"Heteroaryl" refers to a 5 to 6 membered aromatic heterocyclic ring which contains from 1 to 4 heteroatoms selected from the group consisting of oxygen, nitrogen, and sulfur atoms in the ring and may be fused with a carbocyclic or heterocyclic ring at any possible position.

"Heterocycloalkyl" refers to a 5 to 7-membered saturated ring containing carbon atoms and from 1 to 2 heteroatoms selected from N, O, and S.

The term "phenyl", as used herein, whether used alone or as part of another group, refers to a substituted or unsubstituted phenyl group.

An optionally substituted moiety may be substituted with one or more substituents. Suitable substituents for a phenyl or heteroaryl moiety may be selected independently from H, halogen, C1-C6 alkyl, C2-C6 alkenyl, C2-C6 alkyne, NR^4R^5, N[(CH2)2]2O, N[(CH2)2]2NR^4, NHSO2R^4, NR^4C(=O)R^5, NHC(=O)OR^4, NO2, SO2NR^4R^5, SO2R^4, OR^4, C(=O)R^4, COOR^4, CONR^4R^5, and CN.

When such moieties are substituted, for example, they may typically be mono-, di-, tri- or persubstituted. Examples for a halogen substituent include 1-bromo vinyl, 1-fluoro vinyl, 1,2-difluorovinyl, 2,2-difluorovinyl, 1,2,2-trifluorovinyl, 1,2-dibromo ethane, 1,2 difluoro ethane, 1-fluoro-2-bromo ethene, CF2CF3, CF2CF2CF3, and the like.

The term halogen includes bromine, chlorine, fluorine, and iodine.

For the sake of simplicity, connection points ("-"”) are not depicted. When an atom or compound is described to define a variable, it is understood that it is intended to replace the variable in a manner to satisfy the valency of the atom or compound. For example, when L is C(R^6)=C(R^6), both carbon atoms form a part of the ring in order to satisfy their respective valences. Likewise, when divergent substituents are presented, it is understood that they are not
limited to the order listed, for example, as used in this specification "OCH₂" encompasses CH₂O and OCH₂.

The term “pharmaceutically acceptable salt”, as used herein, refers to salts derived form organic and inorganic acids such as, for example, acetic, propionic, lactic, citric, tartaric, succinic, fumaric, maleic, malonic, mandelic, malic, phthalic, hydrochloric, hydrobromic, phosphoric, nitric, sulfuric, methanesulfonic, naphthalenesulfonic, benzenesulfonic, toluenesulfonic, camphorsulfonic, and similarly known acceptable acids when a compound of this invention contains a basic moiety. Salts may also be formed from organic and inorganic bases, preferably alkali metal salts, for example, sodium, lithium, or potassium, when a compound of this invention contains a carboxylate or phenolic moiety, or similar moiety capable of forming base addition salts.

The term “patient”, as used herein, refers to a mammal, preferably a human.

The terms “administer”, “administering”, or “administration”, as used herein, refer to either directly administering a compound or composition to a patient, or administering a prodrug derivative or analog of the compound to the patient, which will form an equivalent amount of the active compound or substance within the patient’s body.

The term “carrier”, as used herein, shall encompass carriers, excipients, and diluents.

The compounds of this invention may contain an asymmetric carbon atom and some of the compounds of this invention may contain one or more asymmetric centers and may thus give rise to optical isomers and diastereomers. While shown without respect to stereochemistry in formula I, the present invention includes such optical isomers and diastereomers; as well as the racemic and resolved, enantiomerically pure R and S stereoisomers; as well as other mixtures of the R and S stereoisomers and pharmaceutically acceptable salts thereof. Thus, an enantiomer substantially free of the corresponding enantiomer refers to a compound that is isolated or separated via separation techniques or prepared free of the corresponding enantiomer. “Substantially free”, as used herein, means that the compound is made up of a significantly greater proportion of one stereoisomer, preferably less than about 50% of the other, more preferably less than about 75%, and even more preferably less than about 90%.

The terms "effective amount", "therapeutically effective amount" and "effective dosage" as used herein, refer to the amount of a compound, that, when administered to a patient, is effective to at least partially ameliorate (and, in preferred embodiments, cure) a condition form which the patient is suspected to suffer.

Biaryl sulfonamide compounds have been found to act as metalloprotease inhibitors. They are therefore useful in the treatment of cancer, osteoarthritis, rheumatoid arthritis, asthma, COPD, atherosclerosis, age-related macular degeneration, myocardial infarction, corneal ulceration and other ocular surface diseases, hepatitis, aortic aneurysms, tendonitis, central nervous system diseases, abnormal wound healing, angiogenesis, restenosis, cirrhosis, multiple sclerosis, glomerulonephritis, graft versus host disease, diabetes, inflammatory bowel disease, shock, intervertebral disc degeneration, stroke, osteopenia, and/or periodontal diseases.

The present invention thus provides pharmaceutical compositions comprising at least one biaryl sulfonamide compound and one or more pharmaceutically acceptable carriers, excipients, or diluents.

Examples of such carriers are well known to those skilled in the art and are prepared in accordance with acceptable pharmaceutical procedures, such as, for example, those described in Remington's Pharmaceutical Sciences, 17th edition, ed. Alfonoso R. Gennaro, Mack Publishing Company, Easton, PA (1985), which is incorporated herein by reference in its entirety.
Pharmaceutically acceptable carriers are those that are compatible with the other ingredients in the formulation and biologically acceptable.

The compounds of this invention may be administered orally or parenterally, neat or in combination with conventional pharmaceutical carriers. Applicable solid carriers can include one or more substances which may also act as flavoring agents, lubricants, solubilizers, suspending agents, fillers, glidants, compression aids, binders or tablet-disintegrating agents or encapsulating materials. They are formulated in conventional manner, for example, in a manner similar to that used for known antihypertensive agents, diuretics and β-blocking agents. Oral formulations containing the active compounds of this invention may comprise any conventionally used oral forms, including tablets, capsules, buccal forms, troches, lozenges and oral liquids, suspensions or solutions. In powders, the carrier is a finely divided solid, which is an admixture with the finely divided active ingredient. In tablets, the active ingredient is mixed with a carrier having the necessary compression properties in suitable proportions and compacted in the shape and size desired. The powders and tablets preferably contain up to 99% of the active ingredient.

Capsules may contain mixtures of the active compound(s) with inert fillers and/or diluents such as the pharmaceutically acceptable starches (e.g. corn, potato or tapioca starch), sugars, artificial sweetening agents, powdered celluloses, such as crystalline and microcrystalline celluloses, flours, gelatins, gums, etc.

Useful tablet formulations may be made by conventional compression, wet granulation or dry granulation methods and utilize pharmaceutically acceptable diluents, binding agents, lubricants, disintegrants, surface modifying agents (including surfactants), suspending or stabilizing agents, including, but not limited to, magnesium stearate, stearic acid, sodium lauryl sulfate, talc, sugars, lactose, dextrin, starch, gelatin, cellulose, methyl cellulose, microcrystalline cellulose, sodium carboxymethyl cellulose, carboxymethylcellulose calcium, polyvinylpyrrolidone, alginic acid, acacia gum, xanthan gum, sodium citrate, complex silicates, calcium carbonate, glycine, sucrose, sorbitol, dicalcium phosphate, calcium sulfate, lactose, kaolin, mannitol, sodium chloride, low melting waxes and ion exchange resins. Preferred surface modifying agents include nonionic and anionic surface modifying agents. Representative examples of surface modifying agents include, but are not limited to, poloxamer 188, benzalkonium chloride, calcium stearate, cetostearyl alcohol, cetomacrogol emulsifying wax, sorbitan esters, colloidal silicon dioxide, phosphates, sodium dodecyl sulfate, magnesium aluminum silicate, and triethanolamine. Oral formulations herein may utilize standard delay or time release formulations to alter the absorption of the active compound(s). The oral formulation
may also consist of administering the active ingredient in water or fruit juice, containing appropriate solubilizers or emulsifiers as needed.

Liquid carriers may be used in preparing solutions, suspensions, emulsions, syrups and elixirs. The active ingredient of this invention can be dissolved or suspended in a pharmaceutically acceptable liquid carrier such as water, an organic solvent, a mixture of both or pharmaceutically acceptable oils or fat. The liquid carrier can contain other suitable pharmaceutical additives such as solubilizers, emulsifiers, buffers, preservatives, sweeteners, flavoring agents, suspending agents, thickening agents, colors, viscosity regulators, stabilizers or osmo-regulators. Suitable examples of liquid carriers for oral and parenteral administration include water (particularly containing additives as above, e.g. cellulose derivatives, preferably sodium carboxymethyl cellulose solution), alcohols (including monohydric alcohols and polyhydric alcohols, e.g. glycols) and their derivatives, and oils (e.g. fractionated coconut oil and arachis oil). For parenteral administration the carrier can also be an oily ester such as ethyl oleate and isopropyl myristate. Sterile liquid carriers are used in sterile liquid form compositions for parenteral administration. The liquid carrier for pressurized compositions can be halogenated hydrocarbon or other pharmaceutically acceptable propellant.

Liquid pharmaceutical compositions, which are sterile solutions or suspensions, can be utilized by, for example, intramuscular, intraperitoneal or subcutaneous injection. Sterile solutions can also be administered intravenously. Compositions for oral administration may be in either liquid or solid form.

Preferably the pharmaceutical composition is in unit dosage form, e.g. as tablets, capsules, powders, solutions, suspensions, emulsions, granules, or suppositories. In such form, the composition is sub-divided in unit dose containing appropriate quantities of the active ingredient; the unit dosage forms can be packaged compositions, for example, packeted powders, vials, ampoules, prefilled syringes or sachets containing liquids. The unit dosage form can be, for example, a capsule or tablet itself, or it can be the appropriate number of any such compositions in package form. Such unit dosage form may contain from about 1 mg/kg to about 250 mg/kg, and may given in a single dose or in two or more divided doses. Such doses may be administered in any manner useful in directing the active compounds herein to the recipient's bloodstream, including orally, via implants, parenterally (including intravenous, intraperitoneal and subcutaneous injections), rectally, vaginally, and transdermally. Such administrations may be carried out using the present compounds, or pharmaceutically acceptable salts thereof, in lotions, creams, foams, patches, suspensions, solutions, and suppositories (rectal and vaginal).

When administered for the treatment or inhibition of a particular disease state or disorder, it is understood that the effective dosage may vary depending upon the particular compound.
utilized, the mode of administration, the condition, and severity thereof, of the condition being treated, as well as the various physical factors related to the individual being treated. In therapeutic application, compounds of the present invention are provided to a patient already suffering from a disease in an amount sufficient to cure or at least partially ameliorate the symptoms of the disease and its complications. An amount adequate to accomplish this is defined as a “therapeutically effective amount”. The dosage to be used in the treatment of a specific case must be subjectively determined by the attending physician. The variables involved include the specific condition and the size, age and response pattern of the patient.

In some cases it may be desirable to administer the compounds directly to the airways in the form of an aerosol. For administration by intranasal or intrabronchial inhalation, the compounds of this invention may be formulated into an aqueous or partially aqueous solution.

The compounds of this invention may be administered parenterally or intraperitoneally. Solutions or suspensions of these active compounds as a free base or pharmaceutically acceptable salt may be prepared in water suitably mixed with a surfactant such as hydroxyl-propylcellulose. Dispersions may also be prepared in glycerol, liquid polyethylene glycols and mixtures thereof in oils. Under ordinary conditions of storage and use, these preparations contain a preservative to inhibit the growth of microorganisms.

The pharmaceutical forms suitable for injectable use include sterile aqueous solutions or dispersions and sterile powders for the extemporaneous preparation of sterile injectable solutions or dispersions. In all cases, the form must be sterile and must be fluid to the extent that easy syringability exists. It must be stable under the conditions of manufacture and storage and must be preserved against the contaminating action of microorganisms such as bacteria and fungi. The carrier can be a solvent or dispersion medium containing, for example, water, ethanol, polyol (e.g., glycerol, propylene glycol and liquid polyethylene glycol), suitable mixtures thereof, and vegetable oils.

The compounds of this invention can be administered transdermally through the use of a transdermal patch. For the purposes of this disclosure, transdermal administrations are understood to include all administrations across the surface of the body and the inner linings of bodily passages including epithelial and mucosal tissues. Such administrations may be carried out using the present compounds, or pharmaceutically acceptable salts thereof, in lotions, creams, foams, patches, suspensions, solutions, and suppositories (rectal and vaginal).

Transdermal administration may be accomplished through the use of a transdermal patch containing the active compound and a carrier that is inert to the active compound, is non-toxic to the skin, and allows delivery of the agent for systemic absorption into the blood stream via the skin. The carrier may take any number of forms such as creams and ointments, pastes, gels and
occlusive devices. The creams and ointments may be viscous liquid or semisolid emulsions of either the oil-in-water or water-in-oil type. Pastes comprised of absorptive powders dispersed in petroleum or hydrophilic petroleum containing the active ingredient may also be suitable. A variety of occlusive devices may be used to release the active ingredient into the blood stream, such as a semi-permeable membrane covering a reservoir containing the active ingredient with or without a carrier, or a matrix containing the active ingredient. Other occlusive devices are known in the literature.

The compounds of this invention may be administered rectally or vaginally in the form of a conventional suppository. Suppository formulations may be made from traditional materials, including cocoa butter, with or without the addition of waxes to alter the suppository’s melting point, and glycerin. Water soluble suppository bases, such as polyethylene glycols of various molecular weights, may also be used.

It is understood that the dosage, regimen and mode of administration of these compounds will vary according to the malady and the individual being treated and will be subject to the judgment of the medical practitioner involved. It is preferred that the administration of one or more of the compounds herein begin at a low dose and be increased until the desired effects are achieved.

The compounds of the invention can be prepared using a variety of methods starting from commercially available compounds, known compounds, or compounds prepared by known methods. General synthetic routes to many of the compounds of the invention are included in the following schemes. It is understood by those skilled in the art that protection and deprotection steps not shown in the Schemes may be required for these syntheses, and that the order of steps may be changed to accommodate functionality in the target molecules.

In Scheme 1 the compounds of the invention, 1, are prepared by hydrolysis of the corresponding esters, 2, where R^10 is an alkyl ester such as methyl, ethyl or t-butyl, or a linker to a Wang resin for solid phase synthesis. Methyl and ethyl esters can be cleaved with aqueous
base, including sodium or lithium hydroxide. t-Butyl esters and esters linked to resin can be cleaved using trifluoroacetic acid or hydrochloric acid. In addition, lithium iodide in ethyl acetate can be used to cleave methyl esters of general structure 2.

Scheme 1:

Routes to compounds of structure 2 are shown in Scheme 2. 4-Nitro biphenyl, 3, is converted into sulfonyl chloride 4 in two steps with chlorosulfonic acid, followed by thionyl chloride or oxalyl chloride with catalytic DMF. Sulfonylation of an α-amino acid derivative, 5, with sulfonyl chloride 4 provides sulfonamide 6. Sulfonamide 6 may optionally be alkylated with an alkyl halide, tosylate, mesylate or triflate (R^{11} = I, Br, Cl, Ots, Oms, OTf) to give the corresponding N-R^3 alkyl sulfonamide. The R^3 side chain can be further functionalized at any point in the synthesis. The NH or N-R^3 sulfonamide is reduced with tin (II) chloride, or hydrogenated over palladium on carbon, or via transfer hydrogenation, to give aniline 7. Aniline 7 is then derivatized to provide 2 by acylation with an acid chloride, or with a carboxylic acid using a peptide coupling reagent such as EDCI, or BOP in the presence of a tertiary amine in a polar aprotic solvent. Sulfonamides 2 are provided by the reaction of aniline 7 with heteroaryl sulfonyl chlorides and a tertiary amine base. Secondary anilines 2 are formed by reductive amination of 7 with a heteroaryl aldehyde in the presence of a reducing agent such as sodium cyanoborohydride or preferably sodium triacetoxyborohydride.
Scheme 2:

An alternative route to amides 2 is shown in Scheme 3. Commercially available sulfonyl fluoride 8 is acylated with acid chlorides to give amide derivatives 9. The analogous sulfonyl chlorides are available from via nitrobenzene 10 through reduction to aniline 11, acylation to give 12 and conversion of the sulfonic acid to the sulfonyl chloride 13. Reaction of amino acids or amino esters, 5, with 9 or 12 in the presence of a tertiary amine base provides compounds 2.
In Scheme 4 amino acid 5 is reacted with 4-bromobenzenesulfonyl chloride to give sulfonamide 14. Palladium catalyzed coupling of 14 with commercially available boronate esters 15 or 16 provides biphenyl sulfonamides 17, where $R^{12}$ is $-\text{OH}$ or $-\text{NH}_2$. Functionalization of the phenol or aniline affords 2. Pyridyl analogs of the biphenyls are prepared by palladium catalyzed conversion of bromophenylsulfonamide 14 to the corresponding boronate ester, 18, followed by palladium coupling with 2-bromo-5-nitropyridine to afford 19. Hydrogenation of 19 gives aniline 20 which can be functionalized to give 2. Similar routes are available to additional heteroaryl analogs of the biphenyl sulfonamides claimed in the invention.
Thioethers of the invention are prepared according to Scheme 5 starting from the commercially available benzylic bromide 21. Displacement of the bromide with heteroaryl thiols in the presence of an acid scavenger provides thioethers 22 which are coupled to bromoaryl 14 using palladium (0) and a base such as potassium carbonate or sodium carbonate to give 23. Ester cleavage of 23 provides thioether compounds of the invention.
Scheme 5:

The biphenylsulfonamides of the invention can also be prepared by the route shown in Scheme 6. Boronate esters 15 and 16 can be functionalized to the corresponding amides, sulfonamides, amines, esters, or ethers prior to palladium catalyzed coupling with bromosulfonamide 14 to give analogs 2. Ester hydrolysis of 2 provides the compounds of the invention. Furthermore, it is understood that the methods shown in Schemes 1-6 for the construction of biphenylsulfonamides are applicable to heteroaryl analogs of biphenyl claimed in the invention.

Scheme 6:
New and known benzofurans of the invention are prepared as shown in Schemes 7-12. Each of the benzofuran esters in Schemes 7-12 can be converted into the corresponding acid, acid chloride, alcohol or aldehyde and coupled as shown in schemes 2-6. It is understood that some of the methodology used for the construction and derivatization of the benzofurans shown is applicable to other heteroaryl ring systems of the invention.

In Scheme 7 salicylaldehydes and ketones 25, bearing a variety of substituents R^7, are alkylated with α-bromoacetic acid esters to give 26 which is next cyclized in the presence of an alkoxide base in alcohol or potassium carbonate in DMF to afford the substituted benzofurans 27. Esters 27 are hydrolyzed with aqueous hydroxide, or TFA (for R^10 = t-buty) to give the carboxylic acids 28, which can in turn be converted into the acid chlorides, 29, with oxalyl or thionyl chloride and catalytic DMF. Reduction of esters 28 with diisobutylaluminum hydride or lithium aluminum hydride gives alcohols 30. The alcohols can be oxidized, preferably with Dess-Martin reagent to give the corresponding aldehydes 31. Alternatively, alcohols 30 can be converted into the corresponding chloride or bromide, 32, with thionyl chloride, phosphorus tribromide, carbon tetrabromide-triphenylphosphine or other known method.

Scheme 7:

Functionalization of the benzofuran core is shown in Scheme 8. Although only 2-, 3-, and 4-substituents are shown on the benzofuran, the methodology shown in the scheme can accommodate additional substituents and the hydroxy group of 33 can be placed at other
positions on the benzofuran. The 4-hydroxybenzofurans, 33, prepared according to Scheme 7, are converted into the corresponding triflates, 34, with trifluoromethanesulfonic anhydride an a tertiary amine, pyridine or lutidine. Palladium catalyzed reaction of 34 with zinc cyanide gives nitriles 35. The nitriles can be hydrolyzed in the presence of H peroxide to give amide 36, which can optionally be alkylated with alkyl halides in the presence of sodium hydride or other strong base. Triflates 34 can also undergo sille coupling with tributylvinyltin, or other alkenyl tin reagent, to provide the styrenes 37. Similarly, triflates 34 can be coupled with alkyne derivatives to provide benzofurans 38-40 where $R^{14}$ is an alkyl or aryl group. Although not shown in the Scheme, the alkenes can be partially hydrogenated to provide olefins, or saturated to give the corresponding alkanes. The alkenes can also be substrates in [3+2] or [4+2] cycloadditions to afford, for example, isoxazoles such as 41.

Scheme 8:

Olefin 37 can be derivatized according to the methods shown in Scheme 9. Dihydroxylation with osmium tetroxide and N-methylmorpholine N-oxide affords diols 42 which can in turn be converted into dioxolanes 43 through the acid catalyzed reaction with acetone or other ketone or aldehyde. Oxidative cleavage of the olefin of 37 with osmium
tetroxide and sodium periodate gives aldehydes 44. The aldehydes can be reduced with sodium borohydride in methanol or ethanol to give alcohols 45, which may in turn be alkylated with an alkyl halide in the presence of silver oxide, sodium hydride or other base. Conversion of 45 to the corresponding bromide with carbon tetrabromide and triphenylphosphine, followed by reduction with sodium borohydride in DMSO, or other known method for the reduction of benzylic alcohols, provides the methyl-substituted benzofurans 46. Hydrogenation of olefins 37 on palladium on carbon gives the ethyl-substituted-benzofurans 47.

Additional transformations of triflates such as 34 are show in Scheme 10. Palladium catalyzed reactions with amines, amides, sulfonamides or carbamates provide derivatives 48-50, each of which can then be further functionalized by alkylation of the newly installed nitrogen with an alkyl halide and base such as sodium hydride. Carbamate 50 can be deprotected by exposure to TFA or HCl to give primary aniline 51. This aniline may be mono- or di-alkylated with an alkyl halide in the presence of potassium carbonate in a polar aprotic solvent to give 48, or acylated or sulfonylated to give 49. Palladium catalyzed Suzuki coupling of triflates 34 with aryl or heteroaryl boronic acids or boronate esters provides 52.
Scheme 10:

The synthesis of acetyl-benzofurans is shown in Scheme 11. Palladium catalyzed coupling of triflate 34 with butyl vinyl ether followed by hydrolysis in aqueous acid gives methyl ketone 53. Reduction of the methyl ketone provides the secondary alcohols, 54, which may in turn be alkylated with an alkyl halide in the presence of silver oxide, sodium hydride or other base.

Scheme 11:

The synthesis of selected 2,4,5-trisubstituted benzofurans (R^6 = H) and 2,3,4,5-tetrasubstituted benzofurans is shown in Scheme 12. Hydroxybenzofuran 33 can be converted into aryl or heteroaryl ethers, 55, by the reaction with aryl/heteroaryl boronic acids in the
presence of copper acetate. Alkyl ether derivatives, 56, are synthesized by alkylation of 33 with alkyl halides in the presence of sodium hydride or potassium carbonate in a polar aprotic solvent such as DMF or THF. Compounds of structure 33 are readily halogenated with N-halogen succinimides to provide compounds 61, which may in turn be alkylated to give ethers 62.

Phenols 33, and their O-alkylated derivatives undergo ortho-acylation with acetyl chloride and titanium tetrachloride to give acetophenones 59, which may in turn be converted into the vinyl chlorides, 60, in the presence of oxalyl chloride and catalytic DMF. Reaction of 33 with magnesium methoxide followed by paraformaldehyde produces the ortho-formyl phenol 57, which can be reduced to the 5-methyl benzofuran 58. The phenol of 58 can subsequently be etherified by reaction with an alkyl halide in the presence of sodium hydride or potassium carbonate.

Certain N-alkyl benzimidazoles of the invention are available as shown in Scheme 13. Thus, 2-methylbenzimidazole, 63, is N-alkylated with an alkyl halide and sodium hydride to give 64, followed by selenium dioxide oxidation to provide the aldehyde, 65. Oxidation of the aldehyde to the carboxylic acid, 66, may be accomplished with silver nitrate. The aldehyde and carboxylate may be coupled with the compounds of Schemes 2-6.
The present invention is further described in the following examples.

Step 1: A suspension of (5-bromo-4-methoxy-3-methyl benzofuran-2-yl)-methanol (0.31 g; 1.1 mmol, Example 136, Step 1) and CuCN (0.21 g; 2.3 mmol; 2 eq) in N-methylpyrrolidinone (1.5 mL) was subjected to microwave radiation at 200°C for 10 minutes. The reaction was diluted with water and ethyl acetate (10 mL each) and filtered. The layers were separated and the aqueous phase was washed with a second portion of ethyl acetate. The combined organic layers were washed twice with water and once with brine. After drying over magnesium sulfate, filtration and concentration in vacuo gave the crude product. Chromatography on silica gel, eluting with 20 % to 30 % ethyl acetate/hexanes gave pure 2-hydroxymethyl-4-methoxy-3-methyl benzofuran-5-carbonitrile (0.17 g; 67 % yield).

Step 2: A solution of 2-hydroxymethyl-4-methoxy-3-methyl benzofuran-5-carbonitrile (0.17 g; 0.76 mmol) in dichloromethane (5 mL) was cooled to 0°C. To this solution was added, successively, neat phosphorus tribromide (0.11 mL; 0.32 g; 1.2 mmol; 1.5 eq) and pyridine (2 drops). The ice bath was removed and the reaction was allowed to come to room temperature overnight with stirring. After quenching with ice, the crude product was isolated by ethyl acetate extraction. The organic layer was washed with saturated sodium bicarbonate, then dried over magnesium sulfate, filtered and concentrated in vacuo to give 2-bromomethyl-4-methoxy-3-methyl benzofuran-5-carbonitrile (0.20 g; 95 % yield).

The combined organic layers were washed with water, 1N sodium hydroxide and brine, then dried over magnesium sulfate, filtered and concentrated in vacuo to give the crude ether as a tan solid. This was chromatographed on silica gel, eluting with 20 % to 30 % ethyl acetate/hexanes, followed by one recrystallization from ethyl acetate/hexanes to give 1-2-[4'-(5-cyano-4-methoxy-3-methyl benzofuran-2-ylmethoxy)-biphenyl-4-sulfonylamino]-3-methyl butyric acid methyl ester as a white crystalline solid (0.28 g; 68 %).

The temperature was then raised to 40°C for 4h whereupon the organic solvent was removed in a stream of nitrogen and the resulting aqueous residue was acidified to pH=3 with concentrated HCl. This was then extracted with ethyl acetate (2x) and the combined organic layers were dried over magnesium sulfate, filtered and concentrated in vacuo to give pure 1,2-[4'-(5-cyano-4-methoxy-3-methyl benzofuran-2-ylmethoxy)biphenyl-4-sulfonylamino]-3-methyl butyric acid as an off-white solid (0.20 g; 73 % yield). Examples 194-247: N-[(4'-[[1-benzofuran-2-ylcarbonyl]amino]-1,1'-biphenyl-4-yl)sulfonyl]-D alanine WAC-549937

![Chemical Structure](image)

Step 1. Biphenyl (46.3g, 0.3mol) was dissolved in 500ml of chloroform. The solution was cooled in an ice/water bath. Chlorosulfonic acid (19.9ml, 1eq) was added dropwise over 30min. The ice/water bath was removed and the reaction mixture was stirred at room temperature overnight. The reaction mixture was filtered and the solid was washed with CHCl₃ to provide 41.2g of biphenyl-4-sulfonic acid as a white solid.

Step 2. Biphenyl-4-sulfonic acid (30g) was mixed with trifluoroacetic acid and a suspension was formed. The mixture was cooled to -5°C. Fuming nitric acid (12.8ml) was added dropwise over 30min. The reaction mixture was stirred at 0°C for 2h. The chloroform was removed in vacuo and the residue was recrystallized from acetic acid to provide 15g of 4'-nitro-biphenyl-4-sulfonic acid, obtained as white crystals.
Step 3. 4'-Nitro-biphenyl-4-sulfonic acid (1.12g, 4mmol) was mixed with tin (II) chloride (5.2g, 32mmol) and 40ml of THF. The mixture was refluxed overnight. The reaction mixture was poured into 80ml of water and stirred at room temperature for 8h. The mixture was filtered and the solid was dried under vacuum to provide 0.73g (73%) of 4'-amino-biphenyl-4-sulfonic acid, obtained as an off-white solid.

Step 4. Benzoferan-2-carboxylic acid (310mg, 1.9mmol) was mixed with 3ml of oxalyl chloride and refluxed for 1h in the presence of a catalytic amount of DMF, then the excess oxalyl chloride was removed by vacuum. The residue was dissolved in 4ml of dichloromethane and was added to a mixture of 400mg (1.6mmol) of 4'-amino-biphenyl-4-sulfonic acid, N,N-diisopropylethylamine (0.92ml, 4eq) and 4ml of THF in an ice/water bath. The mixture was stirred at room temperature for 4h. The reaction mixture was mixed with 2N HCl and in the process a suspension formed. The solid was collected by centrifugation and was washed with chloroform and 2N HCl to provide 540mg of 4'-[(benzofuran-2-carbonyl)-amino]-biphenyl-4-sulfonic acid, obtained as pale brown solid.

Step 5. To 75ml of DMF cooled to -20°C, oxalyl chloride (6.7ml, 76mmol) was carefully added dropwise. A white suspension was formed and the fumes generated were removed by blowing N₂ through the flask. A solution of 4'-[(benzofuran-2-carbonyl)-amino]-biphenyl-4-sulfonic acid (15g, 38mmol) in 100ml DMF was added slowly and the temperature was maintained <0°C. After the addition was complete, the reaction mixture was warmed to room temperature and was stirred at room temperature for 3h. The reaction mixture was poured into 4L ice/water, and the suspension was filtered. The solid was collected and dried under vacuum to provide 7.3g of 4'-[(benzofuran-2-carbonyl)-amino]-biphenyl-4-sulfonyl chloride, obtained as off-white solid.

Step 6: To a solution of D-alanine (0.15 mmol, 14 mg) in water (0.5 mL) and DMF (0.1 mL) was added N,N-diisopropylethylamine (52 uL, 0.3 mmol) and 4'-[(benzofuran-2-carbonyl)-amino]-biphenyl-4-sulfonic acid chloride (0.1 mmol, 41 mg) as a solution in acetonitrile (0.4 mL). The resulting solution was shaken at room temperature for 4 hours and purified by semi-preparative RP-HPLC (Gilson Preparative HPLC conditions: Gilson Preparative HPLC system; YMC Pro C18, 20 mm x 50 mm ID, 5uM column; 2 mL injection; Solvent A: 0.02% TFA/water; Solvent B:0.02% TFA/acetonitrile; Gradient: Time 0: 95% A; 2 min: 95% A; 14 min: 10% A, 15 min: 10% A, 16 min: 95% A; Flow rate 22.5 mL/min; Detection: 254 nm DAD,) to provide N-[(4'-[(1-benzofuran-2-ylcarbonyl)amino]-1,1'-biphenyl-4-yl)sulfonyl]-D-alanine.

Using essentially the same procedures as outlined for Example 194, Step 6, and utilizing the appropriate amino acid, the compounds of Examples 195-247, shown in Table 3, were prepared and purified by preparative reverse phase HPLC².

Example 248: Activity

The activity of the compounds of the invention was assessed through in vitro assays of enzyme inhibition, using MMP-1, MMP-2, MMP-7, MMP-9, MMP-12, MMP-13, and Aggrecanase-1. Inhibitory potencies of some of the compounds of the invention are shown in Table 5 below. Values are given as IC50s in nanomolar, or as percent inhibition at a concentration given in micromolar.

a. *In-vitro* fluorescence assay of MMP-1 activity:

A continuous assay was used in which the substrate is a synthetic peptide containing a fluorescent group (7-methoxycoumarin; Mca) which is quenched by energy transfer to a 2,4-dinitrophenyl group. When the peptide was cleaved by MMP, a large increase in fluorescence was observed. The source of enzyme in the assay was the recombinant human catalytic domain of MMP-1 prepared at Wyeth-Research in Cambridge. The substrate used was Mca-PQGL-(3-[2,4-dinitrophenyl]-L-2,3-diaminopropionyl)-AR-OH (denoted as Wammp-5, custom synthesized by AnaSpec, Inc.). The assay buffer consisted of 50mM Hepes (pH 7.4), 100mM NaCl, 5mM CaCl2, and 0.005% Brij-35. Each well of black polystyrene 96-well plates contained a 200μL reaction mixture consisting of assay buffer, purified MMP (final concentration of 25ng/ml, prepared by diluting with the assay buffer), and varied concentrations of inhibitor (prepared by serially diluting a given inhibitor in DMSO in 96-well polypropylene plate). The plates were then incubated at 30°C for 15 minutes. The enzymatic reactions were initiated by adding the substrate to a final concentration of 20μM, and mixing 10 times with a pipette. The final DMSO concentration in the assay was 6.0%. The initial rate of the cleavage reaction was determined at 30°C temperature with a fluorescence plate reader (excitation filter of 330nm and emission filter of 395nm) immediately after substrate addition.

Plots of the inhibitor concentration vs. the percent inhibition were fit to the following equation: \( y = \frac{(a-d)}{[1+(x/c)^b]}+d \), a general sigmoidal curve with Hill slope, \( a \) to \( d \). \( x \) is the inhibitor concentration under test, \( y \) is the percent inhibition. \( a \) is the limiting response as \( x \) approaches zero. As \( x \) increases without bound, \( y \) tends toward its limit \( d \). \( c \) is the inflection point (IC50) for the curve. That is, \( y \) is halfway between the lower and upper asymptotes when \( x = c \). \( b \) is the slope factor or Hill coefficient.
b. *In-vitro* fluorescence assay of MMP-2 activity:

A continuous assay was used in which the substrate is a synthetic peptide containing a fluorescent group (7-methoxycoumarin; Mca) which is quenched by energy transfer to a 2,4-dinitrophenyl group. When the peptide was cleaved by MMP, a large increase in fluorescence was observed. The source of enzyme in the assay was the recombinant human MMP-2 (66 kDa) purchased from Oncogene Research Products (catalog number PF023 from Calbiochem). The substrate used was Mca-PQGL-(3-[2,4-dinitrophenyl]-L-2,3-diaminopropionyl)-AR-OH (denoted as Wammp-5, custom synthesized by AnaSpec, Inc.). The assay buffer consisted of 50mM Hepes (pH 7.4), 100mM NaCl, 5mM CaCl₂, and 0.005% Brij-35. Each well of black polystyrene 96-well plates contained a 200μL reaction mixture consisting of assay buffer, MMP (final concentration of 25ng/ml, prepared by diluting with the assay buffer), and varied concentrations of inhibitor (prepared by serially diluting a given inhibitor in DMSO in 96-well polypropylene plate). The plates were then incubated at 30°C for 15 minutes. The enzymatic reactions were initiated by adding the substrate to a final concentration of 20μM, and mixing 10 times with a pipette. The final DMSO concentration in the assay was 6.0%. The initial rate of the cleavage reaction was determined at 30°C temperature with a fluorescence plate reader (excitation filter of 330nm and emission filter of 395nm) immediately after substrate addition.

Plots of the inhibitor concentration vs. the percent inhibition were fit to the following equation: \( y = \frac{(a-d)}{[1+(x/c)^b]} + d \), a general sigmoidal curve with Hill slope, a to d. x is the inhibitor concentration under test. y is the percent inhibition. a is the limiting response as x approaches zero. As x increases without bound, y tends toward its limit d. c is the inflection point (IC50) for the curve. That is, y is halfway between the lower and upper asymptotes when x=c. b is the slope factor or Hill coefficient.

The source of enzyme in the assay was the recombinant human catalytic domain of MMP-13 (165 amino acids, residues 104-268, 19kDa) prepared at Wyeth-Research in Cambridge. The substrate used was Mca-PQGL-(3-[2,4-dinitrophenyl]-L-2,3-diaminopropionyl)-AR-OH (denoted as Wammp-5, custom synthesized by AnaSpec, Inc.). A continuous assay was used in which the substrate is a synthetic peptide containing a fluorescent group (7-methoxycoumarin; Mca) which is quenched by energy transfer to a 2,4-dinitrophenyl group. When the peptide was cleaved by MMP, a large increase in fluorescence was observed. The source of enzyme in the assay was the recombinant human catalytic domain of MMP-14 (177 amino acids corresponding to Tyr89-Gly265 of mature human enzyme; 20 kDa) purchased from Chemicon International, Inc. (catalog number CC1041). The substrate used was Mca-PQGL-(3-[2,4-dinitrophenyl]-L-2,3-diaminopropionyl)-AR-OH (denoted as Wammp-5, custom synthesized by AnaSpec, Inc.). The assay buffer consisted of 50mM Heps (pH 7.4), 100mM NaCl, 5mM CaCl₂, and 0.005% Brij-35. approaches zero. As \( x \) increases without bound, \( y \) tends toward its limit \( d \). \( c \) is the inflection point (IC50) for the curve. That is, \( y \) is halfway between the lower and upper asymptotes when \( x = c \). \( b \) is the slope factor or Hill coefficient.

**e. MMP-7 Activity Assay:**

A continuous assay was used in which the substrate is a synthetic peptide containing a fluorescent group (7-methoxycoumarin; Mca) that is quenched by energy transfer to a 2,4-dinitrophenyl group. When the peptide is cleaved by a MMP, a large increase in fluorescence is observed. Active, recombinant human MMP-7 was purchased from Calbiochem (catalog #444270; expressed in *E. coli*, 19kDa). The substrate used was Mca-PLGL-(3-[2,4-dinitrophenyl]-L-2,3-diaminopropionyl)-AR-NH₂ (purchased from Bachem or AnaSpec, Inc; first described by Knight, C.G., Willenbrock, F., and Murphy, G. *FEBS Lett.* (1992) **296**, 263-266). The concentration of the substrate stock was spectrophotometrically determined using the extinction coefficient at 410nm of 7500 M⁻¹cm⁻¹. The assay buffer (pH 7.4) consisted of 50mM Hepes, 100mM NaCl, 5mM CaCl₂, and 0.005% Brij-35. Each well of black polystyrene 96-well plates contained a reaction consisting of assay buffer, purified MMP (final concentration of 1.0 nM, prepared by dilution with assay buffer), and varied concentrations of inhibitor (prepared by serial dilution in DMSO in 96-well polypropylene plates). The plates were then incubated at room temperature for 30 minutes. The enzymatic reactions were initiated by adding substrate to a final concentration of 15μM and were mixed by pipetting up and down. The final DMSO concentration in the assay was 10% and the final, total assay volume was 200 µL. The initial rate of the cleavage reaction was determined at room temperature with a fluorescence plate reader (excitation at 325nm with a 12nm bandwidth and emission at 395nm with a 12nm bandwidth) immediately after substrate addition. Plots of the inhibitor concentration vs. the initial cleavage rate were fit to the following equation in order to determine IC50 values: \( y = V_{max} \cdot (1- (x^n / (K^n + x^n))) \), whereby \( x \) = inhibitor concentration, \( y \) = initial rate, \( V_{max} \) = initial rate in the absence of inhibitor, \( n \) = slope factor, and \( K \) = IC50 for the inhibition curve.

**f. MMP-9 Activity Assay:**

Active, recombinant human MMP-9 (83kDa) was purchased from Calbiochem (catalog #PF024). The assay procedure was identical to that described for MMP-7 except the final enzyme concentration was 0.5-1.0 nM and the final substrate concentration was 20 µM.

**g. In vitro fluorescence assay of MMP-12 activity:**
A continuous assay was used in which the substrate is a synthetic peptide containing a fluorescent group (7-methoxycoumarin; Mca) which is quenched by energy transfer to a 2,4-dinitrophenyl group. When the peptide is cleaved by a MMP, a large increase in fluorescence is observed. The source of enzyme in the assay was the recombinant human MMP-12 (19 kDa; "A280" form) purified at Wyeth Research (Biological Chemistry, Cambridge). The substrate used was Mca-PLGL-(3-[2,4-dinitrophenyl]-L-2,3-diaminopropionyl)-AR-NH₂ (purchased from Bachem or AnaSpec, Inc; first described by Knight, C.G., Willenbrock, F., and Murphy, G. *FEBS Lett.* (1992) **296**, 263-266). The concentration of the substrate stock was spectrophotometrically determined using the extinction coefficient at 410 nm of 7500 M⁻¹ cm⁻¹.

The assay buffer (pH 7.4) consisted of 50 mM HEPES, 100 mM NaCl, 5 mM CaCl₂, and 0.005% Brij-35. Each well of black polystyrene 96-well plates contained a reaction consisting of assay buffer, purified MMP (final concentration of 1.5 nM, prepared by dilution with assay buffer), and varied concentrations of inhibitor (prepared by serial dilution in DMSO in 96-well polypropylene plates). The plates were then incubated at room temperature for 30 minutes. The enzymatic reactions were initiated by adding substrate to a final concentration of 20 μM and they were mixed by pipetting up and down. The final DMSO concentration in the assay was 10% and the final, total assay volume was 200 μl. The initial rate of the cleavage reaction was determined at room temperature with a fluorescence plate reader (excitation at 325 nm with a 12 nm bandwidth and emission at 395 nm with a 12 nm bandwidth) immediately after substrate addition.

Plots of the inhibitor concentration vs. the initial cleavage rate were fit to the following equation: \( y = V_{\text{max}} \cdot (1 - (x^n / (K + x^n))) \), whereby \( x \) = inhibitor concentration, \( y \) = initial rate, \( V_{\text{max}} \) = initial rate in the absence of inhibitor, \( n \) = slope factor, and \( K = IC_{50} \) for the inhibition curve.

**h. Aggrecanase-1 FRET assay:**

The following protocol was used:

Fluorimeter was started and temperature set to 30 °C, about 30 min before setting up the assay. The following reagents are used:

**Buffer:** 50 mM HEPES, pH 7.5, 100 mM NaCl, 5 mM CaCl₂, 0.1 % CHAPS, 5% glycerol.

**rAgg1:** 5 μg/ml (final concentration in the assay):

**Substrate:** WAAG-3R (MWT= 1645.8, AnaSpec, stored at 4° C). Make a stock at 2 mg/ml in 100 % DMSO. Measure the absorbance at 354 nm (\( e=18172 \) M⁻¹ cm⁻¹) to determine the exact concentration. Dilute to 62.5 μM in buffer. Store unused 100 % DMSO stock at −80°
C. Final concentration of substrate in the assay is 25 μM. This concentration is much less than the $K_m$ ($K_m = 1.1 \pm 0.2$ mM as determined by Jin and Cowling).

**Inhibitors.** Make up inhibitors at 10X starting concentration in 100% DMSO. Perform serial dilutions (in duplicate) across the nunc plate in 100% DMSO;

- Dilution plates: Nunc, polypropylene low binding (Nalgene)
- Assay plate: Fluoronunc (Nalgene)
- Fluorimeter: GeminiXS (Molecular Devices).

The assay is performed as follows: The plates are set up so that the final column (12) is used for controls. Total reaction volume is 100 μl. Each compound is assayed in duplicate, so 4 compounds are screened per plate.

1) Add buffer to the entire 96-well plate (30 μl/well).
2) Dilute rAggl to 25 μg/ml buffer just prior to addition on the plate. Add 20 μl/well to all wells. Mix 6 times.
3) Add 10 μl/well of 10x inhibitors from the working plate, **except column 12**. Mix 6 times. To wells 12A-F, add 10X controls (see reference compounds below).
4) To wells 12G-H add 10 μl 100% DMSO.
5) Incubate for 10-15 min at 30°C.
6) Add 40 μl/well of 62.5 μM WAAG-3R substrate. Mix 6 times.

The reaction is monitored for 30-40 min at 30°C. λex: 340 nm and λem: 420 nm). The fluorescence is linear during this time and the slope of the line (Vmax/sec) represents the initial reaction rate, $\nu$. The maximal rate of cleavage of substrate is determined in the absence of inhibitor. The percent inhibition of activity in the presence of inhibitor is calculated as follows:

$$\% \text{ inhibition} = \left(1 - \frac{\nu}{\text{Rate(RFU/sec)}}/\text{Maximal Rate(RFU/sec)}\right) \times 100$$

The IC50 was obtained by fitting the initial rate, $\nu$, or % inhibition at each concentration of inhibitor to the following equation in Excel.

$$y = \frac{(a-d)}{(1+ \frac{C}{IC_{50}})^n} + d$$

This model describes a sigmoidal curve with an adjustable baseline, $a$. $y$ is the % inhibition or initial rate of reaction, $C$ is the concentration of inhibitor under test, $a$ is the limiting response as $C$ approaches zero. As $C$ increases without bound $y$ tends toward its lower limit, $d$. $y$ is halfway between the lower and upper asymptotes when $C = IC_{50}$. $n$ is the Hill coefficient. The sign of $n$ is positive when the response increases with increasing dose and is negative when the response decreases with increasing dose (inhibition).

Table 5 lists the activities for the compounds of Examples 1-179. All values are IC50s in nanomolar, or % inhibition at a concentration (μM).

The disclosures of each patent, patent application, and publication cited or described in this document are hereby incorporated herein by reference, in their entireties.

Various modifications of the invention, in addition to those described herein, will be apparent to those skilled in the art from the foregoing description. Such modifications are also intended to fall within the scope of the appended claims.
What is claimed:

1. A method for modulating the activity of a metalloproteinase comprising contacting said metalloproteinase with an effective amount of a biaryl sulfonamide linked to a heteroaryl moiety.

2. The method of claim 1 further comprising determining the activity of said metalloproteinase.

3. The method of claim 2 wherein said determination is made before said contacting step.

4. The method of claim 2 wherein said determination is made after said contacting step.

5. The method of claim 1, wherein the metalloproteinase is Gelatinase A, Macrophage metalloelastase, Collagenase-3, or Aggrecanase-1.

6. The method of claim 1, wherein the metalloproteinase is Macrophage metalloelastase or Collagenase-3.

7. The method of claim 1, wherein the compound is the formula 1:
