Technical Field

[001] The present disclosure relates to a method for inhibiting BET (bromodomain and extra terminal domain) proteins.

BACKGROUND

[002] Cancer is a group of diseases caused by dysregulated cell proliferation. Therapeutic approaches aim to decrease the numbers of cancer cells by inhibiting cell replication or by inducing cancer cell differentiation or death, but there is still significant unmet medical need for more efficacious therapeutic agents. Cancer cells accumulate genetic and epigenetic changes that alter cell growth and metabolism in order to promote cell proliferation and increased resistance to programmed cell death, or apoptosis. Some of these changes include inactivation of tumor suppressor genes, activation of oncogenes, as well as modifications of the regulation of chromatin structure. Watson, Cancer Discovery 1:477-480 (2011); Morin et al., Nature 478:298-303 (2011).

[003] Many modifications of histones in chromatin have been characterized, including acetylation at multiple lysines in histones H3 and H4. Peserico and Simone, J. Biomed. Botechnoi. 2011:371 832 (2011). Histone acetylation is controlled by acetylases (HATs) as well as deacefylases (HDACs), and small molecule HDAC inhibitors have been developed with cancer as an indication. Hosh sno and Matsubara, Surg. Today 40:809-815 (2010). Histone acetylation controls gene expression by recruiting protein complexes that bind directly to acetylated lysine via bromodomains. Sanchez and Zhou, Curr. Opin. Drug Discov. Devel. 12(5):659~665 (2009). One such family, the bromodomain and extra terminal domain (BET) proteins, comprises Brd2, Brd3, Brd4, and BrdT each of which contains two bromodomains in tandem that can independently bind to acetylated lysines. Wu and Chiang, J. Biol. Chem. 282(18):13141-13145 (2007). BET proteins exert some of their effects on transcription by recruiting the positive transcription elongation factor b (p-TEFb), which stimulates transcription elongation by phosphorylating the C-terminal domain of RNA polymerase II and results in increased expression of growth promoting genes, such as, for example,

[004] Molecules that bind to BET proteins and prevent them from binding to chromatin, inhibit transcription and prevent cell replication, which is useful in cancer therapy and other settings. For example, it has been shown that BET proteins can be displaced from the chromatin by small molecule inhibitors, such as, for example, JQ1, I-BET, and I-BET151, which specifically compete with the acetyl-lysine binding pocket of the BET protein bromodomains thereby preventing transcription elongation of their target genes. Filippakopoulos et al. (2010); Nicodeme et al., *Nature* 468:119-123 (2010); Dawson et al., *Nature* 478:529-533 (2011).

In fact, small molecules that target the bromodomains of BET family members have demonstrated potential therapeutic use in treating cancer. See, for example, Dawson et al. (2011), showing that a small molecule inhibitor of the BET family has a profound efficacy against human and murine mixed lineage leukemia (MLL)-fusion cell lines by early cell cycle arrest and apoptosis. Its mechanism of efficacy is the selective abrogation of Brd3/4 recruitment to chromatin. BET inhibitor JQ1 has demonstrated potent antitumor activity in murine xenograft models of NUT (nuclear protein in testis) midline carcinoma (NMC), a rare but lethal form of cancer. NMC tumor cell growth is driven by a translocation of the Brd4 gene to the nutlin 1 gene. Filippakopoulos et al., (2010). JQ1 was also shown to be a potent antiproliferator in multiple myeloma, associated with cell cycle arrest and cellular senescence. Delmore et al. (2011).

BET inhibitors are also expected to be potential therapeutics for other types of cancer. For example, in acute myeloid leukemia (AML), Brd4 is required to sustain myc expression and continued disease progression. Zuber et al., Nature 478:524-8 (2011). Moreover, inactivation of Brd4 results in a rapid and drastic down-regulation of the transcription of the proto-oncogenes c-myc and n-myc in cell lines they are amplified. Dawson et al. (2011); Delmore et al. (2011); Zuber et al. (2011); Metz et al. (2011). Consequently, treatment of tumors that are characterized by activation or overexpression of c-myc with a BET inhibitor resulted in tumor regression through inactivation of c-myc transcription. BET inhibitors are also expected to have application in multiple myeloma, as the multiple myeloma SET domain (MvLSET) which is implicated in this disease also binds to BET proteins. Dawson et al. (2011).

In addition to cancer, BET inhibitors are also expected to have have anti-inflammatory and immunomodulatory properties. Lamotte et al., Bioorganic & Med. Chem. Letters (February 24, 2012); Prinjha et al., Trends Pharmacol. Sci. 33(3):146-1 53 (2012). BET inhibitors I-BET and I-BET151 decrease IL-6 expression in vivo. I-BET was shown to confer protection against lipopolysaccharide-induced endotoxic shock and bacteria-induced sepsis and I-BET151 was shown to suppress bacterial-induced inflammation and sepsis in a murine model. Nicodeme et al. (2010); Lamotte et al.(2012). In addition, BET
inhibitors may modulate responses to viral and bacterial infections, including HIV, herpes, and papilloma viruses.

Another example of a potentially useful combination is combining a BET inhibitor which decreases myc expression, with an ornithine decarboxylase inhibitor such as difluoromethylornithine, which inhibits a myc target.

Pharmaceutical Compositions

[0105] Pharmaceutical compositions employed in the methods of the invention comprise at least one compound of Formula I, II, III, IV, V, or tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof formulated together with one or more pharmaceutically acceptable carriers. These formulations include those suitable for oral, rectal, topical, intraocular, buccal and parenteral (for example, subcutaneous, intramuscular, intradermal, intravenous, or via implants) administration. The most suitable form of administration in any given case will depend on the degree and severity of the condition being treated and on the nature of the particular compound being used.
[0106] Formulations suitable for oral administration may be presented in
discrete units, such as capsules, cachets, lozenges, or tablets, each containing a
predetermined amount of a compound of the invention as powder or granules; as
a solution or a suspension in an aqueous or non-aqueous liquid; or as an oil-in-
water or water-in-oil emulsion. As indicated, such formulations may be prepared
by any suitable method of pharmacy which includes the step of bringing into
association at least one compound of the invention as the active compound and a
carrier or excipient (which may constitute one or more accessory ingredients). The
carrier must be acceptable in the sense of being compatible with the other
ingredients of the formulation and must not be deleterious to the recipient. The
carrier may be a solid or a liquid, or both, and may be formulated with at least one
compound described herein as the active compound in a unit-dose formulation, for
example, a tablet, which may contain from about 0.05% to about 95% by weight of
the at least one active compound. Other pharmacologically active substances may
also be present including other compounds. The formulations of the invention may
be prepared by any of the well known techniques of pharmacy consisting
essentially of admixing the components.

[0107] For solid compositions, conventional nontoxic solid carriers include,
for example, pharmaceutical grades of mannitol, lactose, starch, magnesium
stearate, sodium saccharin, talc, cellulose, glucose, sucrose, magnesium
carbonate, and the like. Liquid pharmacologically administrable compositions can,
for example, be prepared by, for example, dissolving or dispersing, at least one
active compound of the invention as described herein and optional pharmaceutical
adjuvants in an excipient, such as, for example, water, saline, aqueous dextrose,
glycerol, ethanol, and the like, to thereby form a solution or suspension. In
general, suitable formulations may be prepared by uniformly and intimately
admixing the at least one active compound of the invention with a liquid or finely
divided solid carrier, or both, and then, if necessary, shaping the product. For
example, a tablet may be prepared by compressing or molding a powder or
granules of at least one compound of the invention, which may be optionally
combined with one or more accessory ingredients. Compressed tablets may be
prepared by compressing, in a suitable machine, at least one compound of the
invention in a free-flowing form, such as a powder or granules, which may be
optionally mixed with a binder, lubricant, inert diluent and/or surface active/dispersing agent(s). Molded tablets may be made by molding, in a suitable machine, where the powdered form of at least one compound of the invention is moistened with an inert liquid diluent.

[0108] Formulations suitable for buccal (sub-lingual) administration include lozenges comprising at least one compound of the invention in a flavored base, usually sucrose and acacia or tragacanth, and pastilles comprising the at least one compound in an inert base such as gelatin and glycerin or sucrose and acacia.

[0109] Formulations of the invention suitable for parenteral administration comprise sterile aqueous preparations of at least one compound of Formula I, II, III, IV, V, or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof, which are approximately isotonic with the blood of the intended recipient. These preparations are administered intravenously, although administration may also be effected by means of subcutaneous, intramuscular, or intradermal injection. Such preparations may conveniently be prepared by admixing at least one compound described herein with water and rendering the resulting solution sterile and isotonic with the blood. Injectable compositions according to the invention may contain from about 0.1 to about 5% w/w of the active compound.

[0110] Formulations suitable for rectal administration are presented as unit-dose suppositories. These may be prepared by admixing at least one compound as described herein with one or more conventional solid carriers, for example, cocoa butter, and then shaping the resulting mixture.

[0111] Formulations suitable for topical application to the skin may take the form of an ointment, cream, lotion, paste, gel, spray, aerosol, or oil. Carriers and excipients which may be used include Vaseline, lanoline, polyethylene glycols, alcohols, and combinations of two or more thereof. The active compound (i.e., at least one compound of Formula I, II, III, IV, V, or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof; is generally present at a concentration of from about 0.1% to about 15% w/w of the composition, for example, from about 0.5 to about 2%.
The amount of active compound administered may be dependent on the subject being treated, the subject's weight, the manner of administration and the judgment of the prescribing physician. For example, a dosing schedule may involve the daily or semi-daily administration of the encapsulated compound at a perceived dosage of about 1 µg to about 1000 mg. In another embodiment, intermittent administration, such as on a monthly or yearly basis, of a dose of the encapsulated compound may be employed. Encapsulation facilitates access to the site of action and allows the administration of the active ingredients simultaneously, in theory producing a synergistic effect. In accordance with standard dosing regimens, physicians will readily determine optimum dosages and will be able to readily modify administration to achieve such dosages.

A therapeutically effective amount of a compound or composition disclosed for use in the methods of the invention can be measured by the therapeutic effectiveness of the compound. The dosages, however, may be varied depending upon the requirements of the patient, the severity of the condition being treated, and the compound being used. In one embodiment, the therapeutically effective amount of a disclosed compound is sufficient to establish a maximal plasma concentration. Preliminary doses as, for example, determined according to animal tests, and the scaling of dosages for human administration is performed according to art-accepted practices.

Toxicity and therapeutic efficacy can be determined by standard pharmaceutical procedures in cell cultures or experimental animals, for example, for determining the LD₅₀ (the dose lethal to 50% of the population) and the ED₅₀ (the dose therapeutically effective in 50% of the population). The dose ratio between toxic and therapeutic effects is the therapeutic index and it can be expressed as the ratio LD₅₀/ED₅₀. Compositions that exhibit large therapeutic indices are preferable.

Data obtained from the cell culture assays or animal studies can be used in formulating a range of dosage for use in humans. Therapeutically effective dosages achieved in one animal model may be converted for use in another animal, including humans, using conversion factors known in the art (see, for
example, Freireich et al., *Cancer Chemother. Reports* 50(4):219-244 (1986) and Table 1 for Equivalent Surface Area Dosage Factors).

[0116] The dosage of such compounds lies preferably within a range of circulating concentrations that include the ED$_{50}$ with little or no toxicity. The dosage may vary within this range depending upon the dosage form employed and the route of administration utilized. Generally, a therapeutically effective amount may vary with the subject's age, condition, and gender, as well as the severity of the medical condition in the subject. The dosage may be determined by a physician and adjusted, as necessary, to suit observed effects of the treatment.

[0117] In one embodiment, a compound of Formula I, II, III, IV, V or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof, is administered in combination with another therapeutic agent. The other therapeutic agent can provide additive or synergistic value relative to the administration of a compound of the invention alone. In certain embodiments, a compound of Formula I, II, III, IV, V or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof, is administered in combination with one or more anti-cancer agents.

**Therapeutic Methods**
[01 18] The invention provides methods of treating or preventing diseases or disorders that respond to BET inhibitors, such as, for example, cancer, immune disorders, inflammatory disorders, and diseases caused by bacterial or viral infection. These methods comprise administering to a subject (for example, a mammal, such as a human) a therapeutically effective amount of at least one compound of Formula I, II, III, IV, V, or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof. In another embodiment, at least one compound of the invention may be administered as a pharmaceutically acceptable composition, comprising one or more compounds of Formula I or II and a pharmaceutically acceptable carrier.

[01 19] In some embodiments, the disease or disorder is a cancer which may be treated or prevented by administering a therapeutically effective amount of at least one compound of the invention, i.e., a compound of Formula I, II, III, IV, V or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof.

[0120] In certain embodiments, the cancer to be treated is a midline carcinoma. In some embodiments, the cancer is characterized by c-myc overexpression. In other embodiments, the cancer is characterized by overexpression of n-myc. In certain embodiments, the cancer is Burkitt's lymphoma, acute myelogenous leukemia, multiple myeloma, or aggressive human medulloblastoma. In some embodiments, the cancer relies on the recruitment of p-TEFb to regulate activated oncogenes such as, for example, NOTCH 1. In some embodiments, the cancer to be treated or prevented by the methods of the invention is selected from the group consisting of hematological, epithelial including lung, breast and colon carcinomas, midline carcinomas, mesenchymal, hepatic, renal and neurological tumours.

[0121] The certain embodiments, administration of at least one compound of Formula I, II, [I]: IV, V, or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof to a mammal suffering from a cancer, induces apoptosis in cancer cells by decreasing expression of the anti-apoptosis gene Bcl2. Thus, some embodiments of the invention provide a method of treating or preventing a disease or disorder in a mammal that benefits from increased cell death or differentiation, or decreased cell proliferation, comprising administering at
least one compound of Formula I, II, III, IV, V, or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof.

[0122] In some embodiments of the invention, the at least one compound of Formula I, II, III, IV, V, or tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof is administered in combination with another anti-cancer agent, such as, for example, bortezomib, thalidomide, dexamethasone, 5-azacitidine, decitabine, vorinostat, or cyclophosphamide. In some embodiments, the anti-cancer agent is a PI3K or mTOR inhibitor, such as rapamycin or a rapamycin analog. In some embodiments, the anti-cancer agent is a gamma secretase inhibitor or a AMPK inducer, such as, for example, metformin or phenformin. In certain embodiments, the anti-cancer agent is an ornithine decarboxylase inhibitor, such as, for example, difluoromethylornithine.

[0123] At least one compound of Formula I, II, III, IV, V, or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof may also be administered to treat or prevent a disease or disorder resulting from an infection by bacteria or virus, such as for example, HIV, HPV, or herpes. In some embodiments, the disease or disorder to be treated by the methods of the invention is AIDS. In other embodiments, the at least one compound of Formula I, II, III, IV, V, or a tautomer, stereoisomer, pharmaceutically acceptable salt or hydrate thereof is administered to treat or prevent sepsis in a mammal.

Example 117. Inhibition of tetra-acetylated histone H4 binding individual BET Bromodomains

[0401] Proteins were cloned and overexpressed with a /V-terminal 6xHis tag, then purified by nickel affinity followed by size exclusion chromatography. Briefly, E.coli BL21 (DE3) cells were transformed with a recombinant expression vector encoding /V-terminally Nickel affinity tagged bromodomains from Brd2, Brd3, Brd4. Cell cultures were incubated at 37 °C with shaking to the appropriate density and induced overnight with IPTG. The supernatant of lysed cells was loaded onto Ni-IDA column for purification. Eluted protein was pooled, concentrated and further purified by size exclusion chromatography. Fractions representing monomeric protein were pooled, concentrated, aliquotted, and frozen at -80 °C for use in subsequent experiments.

[0402] Binding of tetra-acetylated histone H4 and BET bromodomains was confirmed by a Time Resolved Fluorescence Resonance Energy Transfer (TR-FRET) method. /V-terminally His-tagged bromodomains (200 nM) and biotinylated tetra-acetylated histone H4 peptide (25-50 nM, Millipore) were incubated in the presence of Europium Cryptate-labeled streptavidin (Cisbio Cat. #610SAKLB) and XL665-labeled monoclonal anti-His antibody (Cisbio Cat. #61 HIXXLB) in a white 96 well microtiter plate (Greiner). For inhibition assays, serially diluted test compound was added to these reactions in a 0.2% final concentration of DMSO. Final buffer concentrations were 30 mM HEPES pH 7.4, 30 mM NaCl, 0.3 mM CHAPS, 20 mM phosphate pH 7.0, 320 mM KF, 0.08% BSA). After 2 hours incubation at room temperature, the fluorescence by FRET was measured at 665 and 620 nm by a SynergyH4 plate reader (Biotek). Illustrative results with the first bromodomain of Brd4 Results are shown in Table 2. The binding inhibitory activity was shown by a decrease in 665 nm fluorescence relative to 620 nm. IC_{50} values were determined from a dose response curve. Compounds with an IC_{50} value less than 50 uM were deemed to be active.

**Example 118: Inhibition of c-rhcy expression in cancer cell lines**

[0403] MV4-11 cells (2.5x10^4 cells) were plated in 96 well U-bottom plates with test compound or DMSO (0.1%), and incubated for 3 hours at 37°C. Cells were then harvested by centrifugation, lysed, and mRNA was isolated using the mRNA catcher plus kit (Invitrogen). Reverse transcription of the mRNA and duplex amplification of the c-myc and cyclophilin cDNAs was performed using the RNA Ultrasense kit (Invitrogen) and a ViiA7 real-time PGR machine (Applied Biosystems). IC_{50} values were determined from a dose response curve. Compounds with an IC_{50} value less than 30 uM were deemed to be active.

**Example 119: Inhibition of Cell Proliferation in Human AML MV4-11 cells**

[0404] MV4-11 cells: 96-well plates were seeded with 5x10^4 cells per well of exponentially growing human AML MV4-11 (CRL-9591) cells and immediately treated with two-fold dilutions of test compounds, ranging from 30 µM to 0.2 µM.
Triplicate wells were used for each concentration, as well as a media only and three DM80 control wells. The cells and compounds were incubated at 37 °C, 5% CO₂ for 72 hours before adding 20 µL of the CeliTiter Aqueous One Solution (Promega) to each well and incubated at 37 °C, 5% CO₂ for an additional 3-4 hours. The absorbance was taken at 490 nm in a spectrophotometer and the percentage of proliferation relative to DMSO-treated cells was calculated after correction from the blank well. IC₅₀ were calculated using the GraphPad Prism software. Compounds with an IC₅₀ value less than 30 µM were deemed to be active.

Example 120: Lipopolysaccharide (LPS) Stimulated Whole Blood Assay for Measuring TNFa and IL-6 Levels

[0405] Activation of monocyctic cells by agonists of toll-like receptors such as bacterial lipopolysaccharide (LPS) results in production of key inflammatory mediators including IL-6 and TNFa. Such pathways are widely considered to be central to the pathophysiology of a range of auto-immune and inflammatory disorders. Compounds to be tested are diluted to give a range of appropriate concentrations and 1 µL of the dilution stocks are added to wells of a 96 plate. Following addition of whole blood (130 µL) the plates are incubated at 37 degrees (5% CO₂) for 30 min before the addition of 10 µL of 2.8 µg/mL lipopolysaccharides.
(LPS), diluted in complete RPMI 1640 (final concentration =200 ng/mL), to give a
total volume of 140 µL per well. After further incubation for 24 hours at 37
degrees, 140 µi of PBS are added to each well. The plates are sealed, shaken
for 10 minutes and then centrifuged (2500 rpm x 10 min). 100 µL of the
supernatant are removed and IL-6 and TNFa levels assayed by immunoassay
(typically by MesoScale Discovery technology) either immediately or following
storage at -20 degrees. BET inhibitors tested in this assay will inhibit the
production of the key inflammatory mediator IL-8 and/or TNFa.

Example 121 : In Vivo Mouse Endotoxemia Model Assay

[0406] High doses of Endotoxin (bacterial lipopolysaccharide) are
administered to animals produce a profound shock syndrome including a strong
inflammatory response, dysregulation of cardiovascular function, organ failure and
ultimately mortality. This pattern of response is very similar to human sepsis and
septic shock, where the body's response to a significant bacterial infection can be
similarly life threatening. To test the compounds for use in the invention groups of
Balb/c male mice are given a lethal dose of 15 mg/kg LPS by intraperitoneal
injection. Ninety minutes later, animals are dosed intravenously with vehicle (20%
cycSodextrin 1% ethanol in apyrogen water) or test compound (10 mg/kg). The
survival of animals is evaluated at 4 days. BET inhibitors tested in the mouse
endotoxemia model assay will result in a significant animal survival effect following
intravenous administration.

Example 122: Growth Suppressive Activity Test Against Cancer Cells

[0407] Using RPMI 1640 medium (manufactured by SIGMA) supplemented
with 10% fetal bovine serum, human promyelocytic leukemia-derived cell line HL-
80, human acute lymphoblastic leukemia-derived cell line MOLT4, human Burkitt's
lymphoma-derived cell line Daudi, and human multiple myeloma-derived cell line
RPMI-8226 are each cultured at 37°C, 5% CO2. In addition, using SSKOV medium
(manufactured by SIGMA) supplemented with 10% fetal bovine serum, human
chronic myeloid leukemia-derived cell line MV4-11 is cultured at 37°C, 5% CO2.
Moreover, using DMEM/F-12 medium (manufactured by SIGMA) supplemented
with 10% fetal bovine serum, human lung cancer cell-derived cell line EBC-1,
human hepatocellular cancer-derived cell line Kim-1, human colorectal cancer-derived cell line HCT-116, human prostate cancer-derived cell line PC-3, human ovarian cancer-derived cell line A278Q, and human osteosarcoma-derived cell line Saos2 are each cultured at 37°C, 5% CO₂. These cells are plated on a 96 well plate, and cultured for 1 day. To each culture test compound diluted with the medium to a final concentration of 0.0003 × 10⁻¹⁰ μm (final DMSO concentration, 0.4%) is added. After culture for 3 more days, WST-8 (0.16 mg/mL) is added to the culture medium and the cells are cultured for 2 hr. The absorbance at 650 nm is subtracted from the absorbance at 450 nm. The growth suppressive activity is shown by a decrease rate of the absorbance of the group receiving test compound to that of the control group, and GI₅₀ value is determined from a dose-reaction curve plotting a decrease rate of the absorbance obtained by changing the compound concentrations.

[0408] This assay demonstrates that a compound that inhibits binding between acetylated histone, more specifically acetylated histone H4, and a bromodomain-containing protein, more specifically human-derived BET family protein BRD2, BRD3 or BRD4 can be used as an antitumor agent.

Example 123: HIV Tat-Mediated Transactivation Inhibition Assay

[0409] This assay evaluates inhibition of Tat-mediated transactivation by BET inhibitors that block the PCAF bromodomain interaction with HIV-1 Tat-AcK50. The effect is assessed by a microinjection study as described previously by Dorr et al. (EMBO J. 21; 271-2723, 2002). In this microinjection assay, HeLa-Tat cells are grown on Cellolocate coverslips and microinjected at room temperature with an automated injection system (Carl Zeiss). Samples are prepared as a 20 μl injection mix containing the LTR-luciferase (100 ng/ml) and CMV-GFP (50 ng/ml) constructs together with 5 mg/ml a chemical compound or pre-immune IgGs. Live cells are examined on a Zeiss Axiovert microscope to determine the number of GFP-positive cells. Four hours after injection, cells are washed in cold phosphate buffer and processed for luciferase assays (Promega). BET inhibitors tested in this assay will inhibit Tat-mediated transactivation by the PCAF BRD inhibitor.

### Observations where certain claims were found unsearchable (Continuation of item 2 of the first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. **[X]** Claim Nos.: 1-26
   - because they relate to subject matter not required to be searched by this Authority, namely:
     
     Claims 1-26 are directed to a method for treatment of the human or animal body by surgery or therapy which the International Search Authority is not required to search. However, this Authority has carried out a search based on the alleged effects or purposes/uses of the product defined in claims 1-26.

2. **[ ]** Claim Nos.:
   - because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. **[ ]** Claim Nos.:
   - because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

### Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. **[ ]** As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. **[ ]** As all searchable claims could be searched without effort justifying additional fees, this Authority did not invite payment of additional fees.

3. **[ ]** As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claim Nos.:

4. **[ ]** No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claim Nos.:

**Remark on Protest**

**[ ]** The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.

**[ ]** The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.

**[ ]** No protest accompanied the payment of additional search fees.
