(54) Title: PLATE, HEAT EXCHANGER AND METHOD OF MANUFACTURING A HEAT EXCHANGER

Fig. 1

(57) Abstract: Plate (1) intended to form a partition between two fluids circulating inside a welded heat exchanger, said plate (1) comprising a plurality of undulations (2) characterised in that all or part of the undulations (2) comprises, on at least one upper crest line (3), at least one preferred contact area (4) that has a height above a nominal height of the undulations (2) of the plate (1), said at least one preferred contact area (4) being intended to come into contact with a lower crest line of an undulation of another plate provided above said plate (1) and to be deformed when the exchanger is manufactured.

PLATE, HEAT EXCHANGER AND METHOD OF MANUFACTURING A HEAT EXCHANGER.**TECHNICAL FIELD**

5 The invention relates to the field of heat exchangers inside which two fluids are circulating one receiving the heat energy of the other. In such exchangers, the fluids can be of the liquid or gaseous type. These fluids circulate between plates that have an optimum exchange surface and a reduced space requirement by means of undulations on either side of a median plane.

10

The invention more particularly targets a type of plate whereof the geometry facilitates the assembly of exchangers with weld assembled plates. This kind of plate welding can be done with or without filler metal or again using a brazing solder.

15 PRIOR ART

In general terms, plates are known that have undulations whereof the upper crest lines of a first plate come into contact with the lower crest lines of a second plate located above. However, when the plates have a ledge which is placed in a facing position in order to commence the welding assembly, two problematic situations are generally noted
20 by the operator.

Indeed, in a first scenario, it is possible for the two plates to come into contact with each other on their edge without the undulations touching each other. The undulations in this situation have a height below their nominal height. So, when a pressure force is
25 exerted on the plates, their edges may overlap locally and the welding bead may well be uneven and not rectilinear in these edge overlay areas.

Furthermore, in the second scenario where the undulations have a height above their nominal height, the edges of the plates no longer come into contact with each other and
30 the welding becomes complex to perform. Leakproofing problems then arise and it is necessary to restart the welding in order to avoid any leaks. Another solution comprises disassembling the plates of the exchanger and then lowering the height of the undulations in such a way as to make the edges correspond with each other.

The purpose of the invention therefore is to allow a simplified design of welded plate heat exchangers in such a way as to guarantee that the plates can easily be assembled with each other.

- 5 A second objective of the invention is to guarantee a perfectly leakproof join by welding between the plates.

DISCLOSURE OF THE INVENTION

- 10 The invention therefore relates to a plate intended to form a partition between two fluids circulating inside a welded heat exchanger, such a plate comprising a plurality of undulations.

- 15 According to the invention, the plate is characterised in that all or part of the undulations comprises, on at least one upper crest line, at least one preferred contact area that has a height above the nominal height of the plate undulations. This preferred contact area is intended to come into contact with a lower crest line of an undulation of another plate provided above the first plate and to be deformed during manufacture of the exchanger.

- 20 In other words, the undulations have localised bumps intended to be deformed when the plates are pressurised against each other. Such a deformation therefore makes it possible to compensate locally for the deviations in the height of the undulations and to adjust the edges of the plates to be welded to each other. Indeed, by compressing the preferred contact areas, it is possible to bring the edges of the plates closer to each other
25 in order to allow them to be secured by welding.

- To advantage, the upper crest line may comprise preferred contact areas spaced out with a constant pitch. In this way, the preferred contact areas are distributed evenly on the surface along a crest line of an undulation.

30

According to a particular embodiment, the pitch separating two preferred contact areas may be equal to the pitch separating two undulations.

In this situation, the preferred contact areas are distributed in such a way as to correspond with each of the successive undulations of the upper plate.

5 In practice, the preferred contact areas may be distributed in at least one continuous strip. Such a strip is generally of narrow width which remains constant on the surface of the plate. The preferred contact areas may thus also be distributed along line segments inscribed in these strips.

10 According to one advantageous embodiment, the plate may comprise a first strip provided on the plate periphery. Indeed, this arrangement is advantageous so as to allow the adjustment of the distance separating the edges of the plates welded to each other.

15 Moreover, the plate can also comprise a second strip provided in a main thermal exchange area of the exchanger. In this situation, vibrations between plates are limited with a consequent reduction in the wear they sustain through fatigue and in the related failure hazards.

To advantage, the preferred contact areas may be provided on undulations positioned in a main thermal exchange area of the exchanger. Such an area generally comprises 20 undulations inclined at 45° relative to the longitudinal direction of the plates. Such an arrangement favours a large contact surface between the two plates.

25 According to one particular embodiment, the preferred contact areas may comprise a length of between 5 and 20 mm. In this way, the positioning of a contact area opposite an undulation on an upper plate is guaranteed, irrespective of geometric deviations in manufacture.

30 In practice, the preferred contact areas may comprise a height of between 0.05 and 1 mm, and preferentially between 0.10 and 0.50 mm and more preferentially between 0.15 and 0.25 mm. Such a height makes it possible to take up the play between the plate edges for welding and thereby to position the edges of the plates opposite one another. Furthermore, such a height may be a function of the dimensions of the plates forming the

exchanger and the pressure allowing these preferred contact areas to be deformed may be adapted as a function of the number of contact points and of the height selected.

5 The invention also relates to a welded heat exchanger, which is characterised in that it comprises at least one plate as previously described.

It also relates to a method of manufacturing a welded plate exchanger. According to the invention, this manufacturing method is characterised in that it comprises steps of:

- deforming preferred contact areas provided on an upper crest line of at least one undulation of a first plate on coming into contact with a lower crest line of an undulation of a second plate provided above the first plate, the contact areas
10 having, prior to deformation, a height above a nominal height of the undulations of the first plate;
- welding the edges of the first and second plates to each other.

15 In other words, such a method comprises a step wherein a pressure force is exerted on the plates in such a way as to deform the preferred contact areas in order to bring the edges opposite one another.

In this way, plates are used whereof the undulations comprise, on an upper crest, at
20 least one deformable area whereof the height is above the nominal height of the plate undulations. In doing this, the positioning of the plate edges is adjusted accurately and the welding process then commences by welding the edges.

25 **BRIEF DESCRIPTION OF THE FIGURES**

The method for implementing the invention and the advantages deriving therefrom will emerge from the following embodiment description, given by way of information and non-restrictively, supported by the figures wherein:

Figure 1 is a perspective view of a stack of plates in accordance with the invention.

30 Figure 2 is a cross-section view of three stacked plates in accordance with the invention.

Figures 3 and 4 are views from above according to two alternatives of the plate.

DETAILED DESCRIPTION OF THE INVENTION

As already mentioned, the invention relates to a plate forming a partition between two fluids inside a welded heat exchanger.

5 As shown in figure 1, such a plate **1** has a plurality of undulations **2**. In accordance with the invention, at least one of these undulations **2** has on an upper crest line **3** preferred contact areas **4** whereof the height is above the nominal height of the undulations **2**. When manufacturing the exchanger all or part of these preferred contact areas **4** are compressed in such a way as to line up the plate edges opposite one another.

10

As shown, these preferred contact areas **4** may be evenly spaced apart with a pitch substantially equal to the pitch of the plate undulations.

15

Furthermore, the height of these preferred contact areas is between 0.05 and 1 mm relative to the nominal height of the plate undulations.

20

As shown in figure 2, the preferred contact area **4** engages with a lower crest line **13** of an undulation **12** of a second plate **11** positioned above the first plate **1**. Likewise, the second plate **11** has preferred contact areas **14** engaging with an upper plate.

25

Moreover, in order to guarantee the engagement between the preferred contact areas **4** of a first plate **1** with a lower crest line **13** of an undulation **12** of a second plate **11**, it is advantageous for the width of the preferred contact areas **4** to be less than twice the pitch separating the undulations **12**.

30

By way of example, the preferred contact areas may have a width of between 5 and 20 mm in such a way as to ensure that the upper undulation bears fully on this contact area.

As shown in figure 3, a plate **1** may comprise preferred contact areas **4**, distributed in a strip **6** extending in proximity to the periphery of the plate **1**. In this way, it is possible to adjust the spacing between the edges of the plates to be welded to each other by exerting a reduced pressure force on the plates to be assembled by welding.

As shown in figure 4, the plate **1** may also comprise preferred contact areas **4**, distributed along two strips **6,16** extending both on the periphery and in the centre of the plate **1**. Thus, the first strip **6** allows an adjustment of the spacing between the edges **7** of the plates to be welded to each other by exerting a reduced pressure force on the plates to
5 be assembled by welding, while the second strip **16** allows a reduction in the vibrations in the plates thereby increasing the fatigue resistance of the exchanger.

This central area of the exchanger may also correspond with a main exchange area **5** of the exchanger. In this main exchange area, the undulations may in particular be
10 inclined at 45° along a main direction of the flux circulating between two plates.

What emerges from the foregoing is that a plate, a heat exchanger and a method of manufacturing this exchanger have many advantages and in particular:

- they make it easier to weld the plate edges to each other;
- 15 ▪ they do not require any special equipment;
- they do not generate any additional costs relative to existing solutions wherein an adjustment of the distance of the edges is not always possible or straightforward.

25

30

Claims

1. Plate (1) intended to form a partition between two fluids circulating inside a welded heat exchanger, said plate (1) comprising a plurality of undulations (2)
5 **characterised in that** all or part of the undulations (2) comprises, on at least one upper crest line (3), at least one preferred contact area (4, 14) that has a height above a nominal height of the undulations (2) of the plate (1), said at least one preferred contact area (4, 14) being intended to come into contact with a lower crest line (13) of an undulation (12) of another plate (11) provided above said plate (1) and to be deformed when the
10 exchanger is manufactured.

2. Plate as claimed in claim 1, characterised in that the upper crest line (3) comprises preferred contact areas (4) spaced apart by a constant pitch.

15 3. Plate as claimed in claim 2, characterised in that the pitch separating two preferred contact areas (4) is equal to the pitch separating two undulations (12).

4. Plate as claimed in claim 1, characterised in that the preferred contact areas (4) are distributed in at least one continuous strip (6, 16).
20

5. Plate as claimed in claim 4, characterised in that it comprises a first strip (6) provided on the periphery of the plate (1).

25 6. Plate as claimed in claim 5, characterised in that it comprises a second strip (16) provided in a main thermal exchange area (5) of the exchanger.

7. Plate as claimed in claim 1, characterised in that the preferred contact areas (4) comprise a length of between 5 and 20 mm.

30 8. Plate as claimed in claim 1, characterised in that the preferred contact areas (4) exceed the nominal height of the undulations (2) by 0.05 to 1 mm.

9. Plate as claimed in claim 1, characterised in that the preferred contact areas (4) exceed the nominal height of the undulations (2) by 0.1 to 0.5 mm.

10. Plate as claimed in claim 1, characterised in that the preferred contact areas (4)
5 exceed the nominal height of the undulations (2) by 0.15 to 0.25 mm.

11. Welded heat exchanger characterised in that it comprises at least one plate (1) as claimed in any of the previous claims.

10 12. Method of manufacturing a welded plate exchanger, characterised in that it comprises the steps of:

- deforming preferred contact areas (4) provided on an upper crest line (3) of at least one undulation (2) of a first plate (1) on coming into contact with a lower crest line (13) of an undulation (12) of a second plate (11) provided above said first plate (1), said preferred contact areas (4) having, prior to deformation, a
15 height above a nominal height of the undulations (2) of the first plate (1);
- welding the edges of the first (1) and second (11) plates to each other.
