(54) Title: APPARATUS AND METHOD FOR DIAGNOSTIC GAS ANALYSIS

(57) Abstract: The invention concerns a handheld, small but accurate and reliable device for diagnostic NO measurements using a NO sensor, where the parameters governing the taking of the sample are different from the parameters optimal for the accuracy of said NO sensor. By temporarily storing a portion of the exhaled air, and feeding this to the sensor at a flow rate adapted to the NO sensor, the accuracy and sensitivity of a system / method involving NO sensors, in particular electrochemical NO sensors, can be increased. The method for diagnostic NO measurements comprises steps for controlling the inhalation of NO free air, as well as the exhalation, both by built-in means and by audible and/or visual feedback to the patient.

Apparatus and method for diagnostic gas analysis

The present invention relates to the field of diagnostic gas analysis, and in particular to the determination of endogenous nitric oxide (NO) in exhaled breath of humans.

5 **Background of the invention**

The discovery of endogenous NO in exhaled air, and its use as a diagnostic marker of inflammation dates back to the early 1990 (See e.g. WO 93/05709; WO 95/02181). Today, the significance of endogenous NO is widely recognised, and since 10 a few years back, a clinical analyser is available on the market (NIOX®, the first tailor-made NO analyser for routine clinical use with asthma patients, AEROCRINE AB, Solna, Sweden).

In the summer of 1997 the European Respiratory Journal 15 published guidelines (ERS Task Force Report 10:1683-1693) for the standardisation of NO measurements in order to allow their rapid introduction into clinical practice. Also the American Thoracic Society (ATS) has published guidelines for clinical NO measurements (American Thoracic Society, Medical Section of 20 the American Lung Association: Recommendations for standardized procedures for the online and offline measurement of exhaled lower respiratory nitric oxide and nasal nitric oxide in adults and children - 1999, in Am J Respir Crit Care Med, 1999; 160:2104-2117).

25 The NIOX® analyser for clinical use, and others mainly intended for research applications, are based on chemiluminescence determination of NO. While highly accurate and reliable, chemiluminescence determination of NO requires an advanced apparatus involving an ozone generator, a vacuum pump, means 30 for dehumidification of the exhaled air, to mention only a few examples. Although the chemiluminescence analysers have

developed significantly, they are still rather expensive and bulky.

Prior art

WO 01/26547 discloses a handheld respiratory NO meter having a low resistance flow pathway throughout the device. Placed in this pathway is a NO concentration sensor generating electrical signals as a function of the instantaneous fraction of NO as the respiration gases pass through the flow pathway. The NO sensor is defined as a fluorescence based sensor having a response time preferably less than or equal to 200 ms, and most preferably less than or equal to 100 ms. Even faster response times are stated to be desirable.

While appealing as a concept, it appears to be practically very difficult if not impossible to achieve accurate and reliable NO determinations in the ppb range using a device according to WO 01/26547.

One objective of the present invention is to make available a portable, preferably handheld device, for diagnostic determinations of NO. Further aims include the goal to make the device easy to use, robust and reliable, while maintaining the high accuracy and sensitivity of the chemiluminescence analysers.

A further objective of the present invention is to make available an interface between the parameters dictated by physiological factors (e.g. Exhalation flow rate, humidity, temperature etc), parameters dictated by standardized medical or diagnostic procedures (sample flow rate, duration etc.), and sensor dependent parameters. Notably said physiological factors may vary between different individuals, depending on age, sex, bodyweight, and state of health. By the term sensor dependent parameters is hereby meant e.g. the temperature

requirements of the sensor, the measurement time necessary for reliable measurements, high and low threshold values for humidity etc.

One particular objective of the present invention is to make

5 available a device for diagnostic NO-measurements operating with an electrochemical sensor, which device is easily used both at home and within a clinical setting, or at point-of-care, however without compromising the accuracy and reliability of the measurements.

10 Another objective is to make available a handheld and robust device, preferably also being a relatively low-cost device, again without compromising the accuracy and reliability of the measurements.

15 Further objectives, solved by the present invention, and advantages associated therewith will become evident from the following description and examples.

Summary of the invention

The objectives of the present invention are met by a device and method according to the attached claims incorporated

20 herein by reference. According to the invention, the device comprises at least one NO sensor, such as an electrochemical NO sensor, an inlet/outlet through which a patient inhales NO-free air through a scrubber, and exhales exhaled air at a predetermined flow rate and pressure, a buffer chamber for

25 temporarily storing a portion of the exhaled air, and means for feeding said stored portion of the sample to said NO sensor during a period of time longer than the duration of the exhalation and/or at a flow rate much below the exhalation flow rate. The method includes at least the steps and

30 operations corresponding to the above.

Short description of the drawings

The invention will be described in closer detail in the following description, non-limiting examples, and claims, with reference to the attached drawings in which:

5 Fig. 1 shows schematically the components of a device according to the invention.

Description

The present inventors have surprisingly shown that an interface can be created between physiologically dictated 10 parameters, as well as parameters dictated by standardized procedures, and the requirements of particular sensors.

This is illustrated by the device and method according to the present invention, in an embodiment of which, the electrochemical sensor technology has been successfully 15 applied in diagnostic measurements of NO.

It is however not possible to apply any NO sensor, such as an electrochemical sensor directly to NO measurements. At the present, electrochemical sensors have a considerably longer response time than other, hitherto used NO sensors, such as 20 the commonly used chemiluminescence sensors. While a chemiluminescence sensor makes an instantaneous determination of the NO concentration in a gaseous sample, an electrochemical sensor requires longer time for establishing a stable signal. Further, electrochemical sensors suffer from 25 high sensitivity to contaminants, sensitivity to variations in humidity, possible cross sensitivity to water or other compounds, low NO sensitivity, as well as a considerable temperature and flow dependence. If correctly calibrated, chemiluminescence sensors are also highly accurate, down to 30 around ± 1 ppb.

Consequently electrochemical sensors have hitherto not been used for diagnostic NO measurements, i.a. due to their long response time, and their relatively high detection levels (low sensitivity) and interference to other compounds.

- 5 As a result of the inventive efforts, it has surprisingly become possible to create a working interface between physiologically dictated parameters, as well as parameters dictated by standardized procedures, and the requirements of particular sensors. A novel device was developed by the
- 10 present inventor in order to make it possible to apply the electrochemical sensor technology to diagnostic NO measurements where a high reliability and accuracy in the lower ppb range (0 to 200 ppb, in particular in the range of 0 to about 50 ppb) is required.

- 15 In general terms, the device according to the invention has the following functionality and/or means for performing said functions (see also Fig. 1):

The device has a combined inlet/outlet 1, capable of engaging a disposable filter (not shown) through which the patient

- 20 first inhales NO-free air via a built-in scrubber 3 removing NO from the ambient air, and then exhales, during which exhalation phase a sample is taken for NO-measurement and led to the sensor.

Preferably the inlet of the device is designed to tightly engage a disposable patient filter / mouthpiece filter. This filter may be a conventional filter, capable of ensuring viral/bacterial free air during normal inhalation, such as a 0.22 μ filter. The filter is preferably a NIOX[®] PATIENT FILTER, marketed by Aerocrine AB, Solna, Sweden (Catalogue no. 02-30 1201).

The patient inhales clean, NO-free air through the mouthpiece / filter, and then exhales through the same filter, into the device. The filter thus fills two functions, as it protects both the patient and the device from particulate matter,

5 viruses, bacterial, aerosols etc. The disposable filter has the added advantage of preventing spread of infections or patient-to-patient contagion.

In the vicinity of the inlet/outlet 1, a pressure sensor 2 is situated. The pressure sensor has the function of monitoring

10 the breath, to ensure that the soft palate is closed during exhalation, to ensure that accurate exhalation pressure is maintained (the option of giving feed-back to the patient may be included) and to check that the inhalation of NO-free air is performed through the apparatus, i.e. through the NO-
15 scrubber 3. The device also has an inlet 4 for ambient air, leading to said scrubber 3. The scrubber in turn is connected via a one-way valve 5 to the inlet/outlet 1, so that the patient can inhale NO-free air, but preventing exhaled air to pass said one-way valve.

20 The scrubber may be a conventional chemical NO scrubber, having an inlet and an outlet, and a main body filled with suitable filter media, e.g. a KMnO₄ based filter media, or a carbon based filter with suitable chemical additives. The construction of the filter, and arrangements for taking a zero
25 sample is the subject of a co-pending patent application.

Further, in connection to the inlet/outlet 1 is a flow regulator 6, which has the function of controlling the exhalation flow with high accuracy to 20 - 800 ml/s,

preferably 50 ml/s (\pm 5 ml/s) when the user adapts to the

30 feedback given by the device. Said flow regulator may be a passive flow restrictor, or an active regulator with means for measuring the flow and adjusting elements of said regulator,

or by giving feed back to the patient, guiding the exhalation flow. According to one embodiment, the flow regulator automatically adjusts to the exhalation flow, limiting excess flow. According to another embodiment, the flow regulator is 5 capable of adjusting to two or more pre-set levels of flow, during one exhalation, or during two or more subsequent exhalations.

The exhalation air is then led, through the flow regulator 6, to a buffer chamber 7, at the end of which a flush valve 8, 10 and a three-way valve 9, are situated. During the initial phase of the exhalation, the flush valve 8 is open, and the three-way valve 9 closed, and the exhaled air is thus led to the ambient atmosphere. At a predetermined time, the flush valve 8 will close, and the three-way valve 9 open, so that 15 the sample stored in the buffer chamber 7 will be led through the three-way valve 9, with the aid of a sample pump or fan 10, to the sensor 11.

The sensor may be any suitable NO sensor, e.g. a chemical, 20 electrochemical, ultrasonic or other, preferably an electrochemical sensor.

According to a preferred embodiment of the invention, the sample pump 10 is a plunger pump. This type of pump has the advantages of being insensitive to variations in flow, and gives a low, even flow with high accuracy.

25 Before reaching the sensor, the sample is preferably led through means 12 for equalising the humidity of the sample to ambient conditions, and means 13 for equalising the temperature of the sample to the same stabilised temperature as that of the sensor, which, according to an embodiment, is 30 controlled to a set temperature, different from the ambient temperature.

Preferably said means 13 acts to temperate both the sample and the sensor, e.g. by surrounding the sensor and by forming a large contact area for the gas flow. Alternatively, the temperature of the sample and/or that of the sensor is 5 measured, and the results compensated for the temperature according to the specifications of the sensor.

The device further comprises means for controlling the functions of the above means, such as control electronics 14, which receive and analyse input e.g. from the sensors, and the 10 user interface, and control the valves and the sample pump. The means 14 will also handle data acquisition, signal processing, data storage, communication with external units, and the user interface. External communication can be performed using one or several of the following options: a 15 memory card or microprocessor card, an EEPROM card, in the following designated "smartcard", IR-communication, BLUETOOTH®, or other form of wireless communication, or via a conventional serial or parallel port.

The provision of a smartcard has, among other advantages, the 20 particular advantage that every patient is free to use any device according to the invention, and information relating to the patient will automatically be stored in the device, together with the measurement results. Simultaneously, information relating to the device and sensor will 25 automatically be stored on the smartcard, together with the measurement results. This gives greatly added flexibility, without compromising the documentation requirements in diagnostic applications.

The device further comprises a user interface 15, one 30 component of which has the form of a display, such as a liquid crystal display (LCD), preferably a touch screen, for displaying data to the user, and for receiving commands and

settings from the user, e.g. for programming and/or parameter setting, functionality check or similar, performed by a qualified user, or by specifically designated service staff. Alternatively, these functions or part thereof may be 5 performed through a conventional PC-interface, e.g. a conventional serial port (e.g. a USB port), or a parallel port.

The device preferably also comprises means for keeping track of current date and time, as well as means for setting the 10 current date and time. There is preferably also an alarm function, which can be set for single or recurrent alarms, for example a specific time every day. It is possible to set the alarm time and recurrence, as well as to enable / disable the alarm. The alarm function has the advantage of improving 15 patient compliancy with regard to monitoring their condition, and hopefully also with regard to the treatment of the same.

In summary, the input reaching the means 14 consist of signals from the pressure sensor, the NO sensor, the user interface, external communication interfaces, and the temperature 20 control. The output leaving the means 14 consist of signals regulating the position of the flush valve, the three-way valve, the sample pump, the temperature control and the user interface.

In the device according to the invention, the sample of 25 exhalation air may be collected in accordance with the standardised exhalation manoeuvre (See ERS Guidelines 1997, ATS Guidelines 1999, *supra*) where after it is temporarily stored in a buffer chamber, which makes it possible to expose the sensor to a zero-sample or a patient sample at a steady 30 flow, during a prolonged period of time, in order to obtain an accurate response from the sensor.

The device according to the invention includes a buffer chamber, and means for filling said buffer chamber during controlled exhalation, thus taking a sample of exhaled air for NO measurement. The volume of said buffer chamber is chosen so

5 that it is sufficient to hold a sample, which then can be delivered to the sensor during a prolonged period of time, e.g. a volume of 150 ml. The means for filling said buffer chamber may include a valve or a set of valves. The means for filling said buffer chamber with a sample of exhaled air is

10 preferably a valve allowing exhaled air to fill the buffer chamber during a pre-set duration of the exhalation.

The means for supplying the sample to the sensor preferably consist of a sample pump or fan.

Further, there are means for supplying NO-free air to the

15 sensor, said means preferably consisting of a pump or fan, drawing air through a NO-scrubber. This pump or fan may be identical to that supplying the sample to the sensor, the source of gas (patient sample / zero sample) being controlled by one or several valves.

20 When the buffer chamber is filled with the desired sample, said means for delivering the sample to the sensor is/are activated. Such means include a sample pump or fan, supplying the sensor with a flow of about 0.5 to 15 ml/s, preferably from about 2 to about 10 ml/s during a predetermined time,

25 longer than the exhalation time. This time is set in relation to the properties of the sensor, its sensitivity and configuration. The time can be chosen in an interval of about 15 to about 300 s, and preferably when the flow is about 2 ml/s, the time will be about 30 s or about 50 s, again

30 depending on the requirements and properties of the sensor.

The buffer chamber is a space for temporarily storing a portion of exhaled breath, in order to deliver it to the

sensor at a flow and during a duration of time, adapted to the response time of said sensor. Preferably said buffer chamber is a space, which meets at least one of the following requirements:

- 5 - no significant diffusion of NO into the walls of the buffer chamber
- no significant diffusion of substances which interfere with the NO measurement
- turbulent flow
- 10 - no significant adhesion of NO to the inner walls

According to one embodiment of the invention, said buffer chamber is formed as a long channel with small cross-section, e.g. a maze with a round, elliptic, square or rectangular cross section, e.g. moulded in a block of thermoplastic

15 material.

According to another embodiment, said buffer chamber is formed as a length of tubing of a suitable, inert material, such as polyolefine tubing.

According to yet another embodiment, said buffer chamber is 20 formed as a cylinder with a movable end wall or piston. By operating said end wall or piston longitudinally, sample is aspirated into and displaced out from the cylinder. This embodiment can be exemplified by a syringe where the volume of the syringe corresponds to the volume of the sample to be 25 taken, and the rate at which the piston displaces the sample is equal to the rate at which the sample is to be fed to the sensor.

According to yet another embodiment, said buffer chamber is 30 formed as a bellows of a suitable material. The sample is allowed to enter the bellows, either by the pressure exerted by the patient when exhaling into the device, or aided by

mechanically expanding the bellows. The sample is then displaced by mechanically compressing the bellows.

According to another embodiment, the buffer chamber is adapted for sequential storage, i.e. the storage of many sequential 5 samples. The channel preferably has a geometry which maximizes turbulence in order to minimize mixing due to laminar layers, e.g. a channel with varying cross-section or having deliberate disturbances to flow.

In the determination of nitric oxide concentration using an 10 electrochemical sensor, both the temperature of the sensor and the gas flow are critical factors. The temperature of the sensor influences its sensitivity, and consequently fluctuating temperatures between separate measurements will result in poor repeatability and reduced precision and /or 15 accuracy. Correspondingly, the temperature of the gas flow, as it meets the surface of the sensor, will influence the temperature of the sensor, with the above consequences.

In the device according to the present invention, and in the corresponding method, the temperature may be registered, and 20 the results adjusted to the temperature using a correlation factor. Preferably, the temperature of both the gas and the sensor is accurately controlled by providing the sensor with means which temperate both the sensor and the sample gas before it reaches the sensor. The construction of such means 25 is the subject of a co-pending patent application.

Electrochemical sensors are known to be sensitive to fluctuations in humidity. The device according to the invention preferably includes means for equalising the humidity of the sampled exhalation air, as well as that of the 30 zero sample, with ambient humidity. Such means may consist of a length of NAFION® tube, through which the sample is led (NAFION® is a perfluorinated polymer membrane, the trademark

being the property of E.I. du Pont de Nemours & Co, Delaware, USA). The advantage of this lies in that the patient sample and the zero sample will have the same humidity when reaching the sensor.

5 Electrochemical sensors unfortunately tend to have a limited life span, due to the electrolyte depletion.

According to the method and device of the present invention, the life span of the sensor is subject of a two-fold consideration. The device is equipped with means capable of 10 establishing the production date and/or calibration date and/or expiration date of the sensor, e.g. by reading such information stored in association to the sensor, preventing use of the sensor according to pre-set criteria, e.g. when the expiration date is reached.

15 The device is further equipped with means for registering the number of measurements performed with a sensor, and preventing use of the sensor according to pre-set criteria, e.g. detection or determination of necessary sensor parameters.

The above means and associated functions have the advantage of 20 making it possible to guarantee that each measurement is performed with a well functioning sensor.

The device according to the present invention has a novel, greatly simplified visual interface. The visual interface comprises a display, which indicates the state of the device 25 (e.g. ON / START UP / READY / BUSY / OFF etc.) and guides the user through the inhalation and/or exhalation, and presents the result of the measurement. This display is preferably a conventional display, such as a liquid crystal display (LCD). Most preferably said display is a so called touch screen.

30 The above functions can be further supported by visual and audible signals, such as one or more blinking light/-s, user

messages on a display, signals consisting of different symbols or colours, an audible signal which changes in tone or rhythm, all depending on the state of the device, or on the performance of the patient when inhaling and/or exhaling. For 5 example, the device may display one symbol or colour when in START UP mode, and another symbol or colour when the START UP mode is completed, and the device is ready for measurements or enters READY mode. Likewise, the device may display one first symbol or colour, either blinking or steady, when the user 10 inhales and/or exhales incorrectly, and then another second symbol or colour or other signal, clearly distinguishable from said first symbol, colour or signal when the inhalation and/or exhalation is performed according to pre-set requirements, ensuring good repeatability of the measurements. Parameters to 15 be controlled and associated to visual and/or audible signals include the duration and pressure of the inhalation, and the exhalation, respectively.

The above means and associated functionalities make the device suitable for use by all patients, either alone or under the 20 supervision of medical personnel, e.g. their treating physician or a nurse, for point-of-care use, as well as for home use by individual patients, monitoring their disease.

The device according to the present invention is preferably capable of communicating with its surroundings in many ways. 25 With the patient, the device will communicate audibly and/or visually, indicating basic functions, state of readiness, proper use (inhalation, exhalation) and the result of the measurement. It is possible e.g. to send configuration data between an external software and a smartcard via the device.

30 Further, the device preferably includes an IR port for communication with a computer, e.g. for storing patient data in a database, for further analysis of the data or a separate

IR printer for measurement report print-out. The IR port may also work to incorporate the device in a local network, enabling the use of local printers or in other ways to handle measurement results and patient information.

- 5 The device according to the invention preferably also includes a smartcard interface for entering and storing individual patient data. When using the device outside a clinical setting, each user would be given a personal smartcard. Preferably the smartcards would be pre-programmed to contain
- 10 the settings relevant for different patient groups, e.g. male, female, child, or the settings relevant to patients of different race, age or bodyweight, in order to account for differences in dead space, or other physiologic differences.

The NO measurement results would then be recorded on the

- 15 internal device memory and on the smartcard, together with information regarding the identity of the device and sensor used in the measurement, the date and time of the measurement, and optionally the ambient temperature and humidity. According to one embodiment, the smartcard would be designed to carry
- 20 the patient history, and NO levels, optionally together with information regarding medication, doses, disease parameters, and subjective information, such the state of health, assessed by the patient or by the treating physician or nurse.

According to another embodiment, the smartcard is configured

- 25 while inserted in the device but using external software.

The device is preferably also capable of communicating with external software, installed on an external computer, such as a PC. It is then possible e.g. to send measurements and other stored data from a smartcard (via the inventive device) to

- 30 said external software.

According to one embodiment, it is also possible to send measurement data and other stored data from the internal memory of the device to external software.

Likewise, according to another embodiment, it is also possible 5 to download software updates to the inventive device from external software.

It is preferably further possible to send service and support parameters, such as an error log from the inventive device to external software.

10 The device according to the present invention may further include an AC/DC converter, preferably an external converted feeding the device with DC. The device may further contain a rechargeable battery, a power unit supplying the required voltage to the components of the device. A battery for memory 15 and sensor back-up is also included in the system.

The device according to the invention preferably comprises an internal memory, preferably with the possibility to store data from at least 2000 measurements. Alternatively, or in addition to the internal memory, the device will be capable of 20 recording information on a removable data medium, such as a so called smartcard, a memory card, a microprocessor card, an EEPROM, a mini disc, diskette, or the like. The data to be recorded in the internal memory and/or on a smartcard or similar may comprise:

- 25 - patient ID
- date and time of measurement
- measured FE_{NO}
- sensor ID No.
- device ID No.

30 - disease and comfort parameter inputs in an advanced operating mode

- medication parameter inputs in an advanced operating mode

Optionally, when measurement data memory is full, a warning is issued and, following confirmation of said warning, the oldest data may be overwritten with new data.

Preferably also an error list is provided either in the
5 internal memory, or on the smartcard, or in duplicate on both
of these, consisting of at least the following entries:
- error number
- timestamp

According to a preferred embodiment, patient configuration is
10 stored on the smartcard. The patient information may be
general information, relating to different patient groups,
such as male/female, child/adult/elderly, and further
information, if diagnostically relevant. Preferably the
smartcards are colour coded, each colour corresponding to one
15 patient group. Preferably the smartcards are printed with a
clearly visible number or code, so that individual cards can
be distinguished. Preferably the smartcards have an area where
the name of the patient can be printed or hand-written.

The patient information may also be individual information,
20 relating to a specific patient. In both cases, the information
may comprise:
- recommended max FE_{NO} value
- recommended min FE_{NO} value
- one of the available patient age group modes (via chosen
25 smartcard)

The internal memory of the device according to the invention
is preferably able to store both NO measurements and user
input, including input e.g. by manufacturer and information
for maintenance personnel. For example, the device is able to
30 store errors to said internal memory.

The device is preferably also able to store configuration parameters to the internal memory, such as:

- production date
- calibration date

5 - sensor input calibration parameters

The device is preferably also able to store settings and operating parameters to the internal memory, such as:

- top LED intensity
- volume

10 - contrast

- alarm time
- current time and date

According to a preferred embodiment, the electrochemical NO sensor is integrated to a circuit comprising a memory, in the following called "sensor memory". This is preferably a memory circuit of EEPROM-type. Said sensor memory is capable of communicating and/or interacting with the internal memory and control circuits of the device.

In other words, it will be possible to read data from the sensor memory, such as:

- sensor calibration data
- expiration date
- sensor depletion control parameters
- sensor integrity data

25 It is also possible to count down the remaining number of measurements on sensor at the rate at which measurements are performed.

According to a preferred embodiment, the inventive device will be capable of indicating when the expiration date of the sensor is approaching, or when the remaining number of measurements reaches a predetermined low value, and alerting the user. When the expiration date is reached, or when the

number of measurements exhausted, the device will block further use of the sensor and alert the user.

According to the invention, the device keeps track of current time and date. It will also be possible to set current time 5 and date, and current time and date is retained during backup battery operation.

There are numerous advantages related to the provision of a sensor memory. One is safety, as the expiration date will be automatically checked, and the use of the sensor automatically 10 blocked when this date is passed. Another safety issue is the automatic control of the number of measurement, where the use of the sensor is automatically blocked when a maximum number of measurements is reached.

There may also be provided a feature for measuring ambient NO 15 levels with the device. The ambient measurement process may consist of ambient stabilization, ambient measure, zero stabilization and zero measure phases in mentioned order. The process is similar to that of the diagnostic NO measurement, with the exception that the sample pump is used to extract the 20 sample directly from the ambient air.

The result of the measurement is calculated with account to calibration constants in order to obtain the ppb value.

The device according to the invention preferably includes means and functions for temperature control. According to one 25 embodiment, the means for temperature control consist of a Peltier element. The sensor temperature is kept at value set in internal configuration memory: If the measured temperature is outside the set conditions for use, the element will be off.

30 The temperature will be considered invalid if it has been outside the controlled temperature range for a preset period

of time. If the temperature is invalid for a preset period of time, an error message is issued.

According to the invention, pressure is always measured relative ambient pressure. Ambient pressure is defined as the 5 pressure when the user requests a measurement. During a pre-set duration of the inhalation, the pressure is required to be maintained below a value set in the internal configuration memory. During the exhalation phase, the pressure is further required to be maintained within max and min values set in the 10 internal configuration memory. During the exhalation phase, a warning will be issued if the pressure is not within the range defined by high and low values set in the internal configuration memory. During the processing phase, after a preset transition time, the pressure is required to remain at 15 ambient level.

According to one embodiment, the device includes a smartcard interface. The smartcard is inserted by the user when activating the device or before a measurement is performed, and is to remain inserted during the entire measurement 20 process. If there is less than 10% free measurement storage capacity on said smartcard, the user will be notified before measurement.

The device and method according to the invention preferably also comprises a self-test function. If self-test fails an 25 error message will be issued.

According to one embodiment, errors are always logged to database on main board memory. If a patient smartcard is inserted when an error occurs, the error will be logged to smartcard.

30 Importantly, the user will be notified when an error occurs.

The device and method according to the present invention offers many advantages. Numerous sources of error are avoided, or minimized.

For example, as the device registers the negative pressure 5 when a patient inhales through the device, and thus through the NO scrubber supplying NO free air, the correct performance of the inhalation is controlled. The pressure check is further supplemented by feedback, guiding the patient to perform a correct inhalation and exhalation, or informing the patient 10 when the inhalation and exhalation was correct, and when the breathing maneuver were insufficient.

The device and method further have built-in means and functions or operations, which constantly ensure that the electrochemical sensor functions properly.

15 One major advantage of the device and method according to the invention is the fact that it becomes possible to take a sample from a patient according to parameters dictated by the physiology of said patient, and according to parameters dictated by standardized procedures valid in medicine and 20 diagnostics, while performing the analysis of the sample according to parameters optimal for the chosen sensor.

This is here illustrated by a device for the analysis of NO in exhaled breath using an electrochemical sensor, but the present invention is also applicable to the analysis of NO or 25 other components, in samples other than exhaled air.

Although the invention has been described with regard to its preferred embodiments, which constitute the best mode presently known to the inventors, it should be understood that various changes and modifications as would be obvious to one 30 having the ordinary skill in this art may be made without

departing from the scope of the invention as set forth in the claims appended hereto.

THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:

1. A device for diagnostic NO measurements, which device comprises a NO sensor, control electronics, an inlet through which a patient exhales at a predetermined first flow rate and pressure, a buffer chamber for temporarily storing a portion of the exhaled air, and means for feeding said portion of the sample to said NO sensor at a second flow rate suitable for said sensor, said second flow rate being lower than said first flow rate, wherein said means for feeding said portion of said sample to said NO sensor comprises at least one device selected from the group consisting of a pump and a fan.
- 5 2. The device according to claim 1, wherein the device comprises a flow regulator for controlling the exhalation flow and establishing a first flow rate.
- 10 3. The device according to claim 1 or claim 2, wherein the means for feeding said portion of the sample to said NO sensor operates to create a second steady flow of about 0.5 to 10 ml/s during a time period longer than the duration of the exhalation.
- 15 4. The device according to any one of claims 1 to 3, wherein the device comprises means for equalizing the humidity of the sample.
- 20 5. The device according to claim 4, wherein said means for equalizing the humidity of the sample consist of a length of tube, made from a catalytic membrane material.
- 25 6. The device according to any one of claims 1 to 5, wherein the device comprises means for verifying the parameters of the inhalation and controlling the parameters of exhalation.
7. The device according to claim 6, wherein said means comprise a pressure sensor and means for giving feedback to the patient.
- 20 8. The device according to claim 6, wherein said means further comprise a flow sensor and means for controlling the flow and/or giving feedback to the patient.

9. The device according to claim 6, wherein said means further comprise a pressure sensor capable of measuring absolute pressure in order to make it possible to compensate for varying partial pressure of NO depending on variations in ambient pressure.
- 5 10. The device according to any one of claims 1 to 9, wherein the buffer chamber is a maze.
11. The device according to any one of claims 1 to 10, wherein the buffer chamber consists of a cylinder with a movable piston.
12. The device according to any one of claims 1 to 11, wherein the buffer chamber consists of a length of tube.
- 10 13. The device according to any one of claims 1 to 12, wherein the device comprises a NO-scrubber through which a patient inhales directly prior to exhaling into the device, thus ensuring that the dead space of the respiratory tract of the patient is filled with NO-free air.
- 15 14. The device according to any one of claims 1 to 13, wherein the device further comprises an interface for receiving a smartcard on which data linked to a specific user can be stored, and onto which measurement data can be recorded.
15. The device according to claim 14, wherein the device is capable of adapting to different users or different user groups, based on the data stored on the smartcard.
- 20 16. The device according to claim 3, wherein the means for feeding the sample to the NO sensor is a plunger pump.
17. The device according to claim 3, wherein the means for feeding the sample to the NO sensor is a fan.
- 25 18. The device according to any one of claims 1 to 17, wherein said NO sensor is an electrochemical sensor.
19. A method for measuring exhaled NO using a device according to any one of claims 1 to 18, characterized in that:

- a sample of exhaled air is collected at a first preset flow rate and pressure and temporarily stored in a buffer chamber,
- said sample is fed to said NO sensor at a second flow rate suitable for said sensor, and

5 - the NO concentration is determined in said sample.

20. The method according to claim 19, wherein said second flow rate is lower than said first flow rate.

21. The method according to claim 19, wherein said second flow rate is a steady flow of about 0.5 to 10 ml/s during a time period longer than the

10 duration of the exhalation.

22. The method according to any one of claims 19 to 21, wherein said first flow rate is in the interval of about 20 to 800 ml/s and said second flow rate is in the interval of about 0.5 to 10 ml/s.

23. The method according to claim 19, wherein said NO sensor is an

15 electrochemical sensor.

24. A method for diagnostic NO measurements using a device comprising a NO sensor, characterized in that:

- a patient exhales into said device,
- the exhalation flow rate and pressure is controlled to at least one preset value, respectively,
- a sample of the exhalation air is temporarily stored in a buffer chamber,
- said sample is fed to said electrochemical NO sensor at a flow rate suitable for said sensor, and

20 - the NO concentration is determined in said sample.

25. The method according to claim 24, wherein the patient inhales NO-free air prior to exhaling into the device.

26. The method according to claim 24, wherein the patient inhales through a NO-scrubber integrated in said device, supplying NO-free air to the patient, prior to exhaling into the device.
- 5 27. The method according to any one of claims 24 to 26, wherein the patient is given audible or visual feedback during the inhalation and exhalation steps, in order to support the correct performance of said steps.
- 10 28. The method according to any one of claims 24 to 27, wherein the exhalation flow rate is controlled to a value of about 20 to 800 ml/s and the rate at which the sample is fed to the sensor is about 0.5 to 10 ml/s.
- 15 29. The method according to any one of claims 24 to 28, wherein said NO sensor is an electrochemical sensor.
30. The method according to any one of claims 24 to 29, wherein the sample flow rate when led to the sensor is lower than the exhalation flow rate.
- 15 31. A method according to any one of claims 24 to 30, wherein at least one of the following steps is included:
 - the patient enters information relating to his/her intake of a medicament
 - 20 - the patient subjectively assesses his/her state of health and enters corresponding information.
32. A computer program comprising the instructions for performing the method according to any one of the claims 19 to 31.
33. The computer program according to claim 32, when stored on a medium.
- 25 34. A method for the diagnostic determination on NO in a gas sample, where the parameters governing the taking of the sample are different from the parameters optimal for the accuracy of the NO measurement, characterized in that a device according to any one of claims 1 to 18 is used.
