REGULATION 9

COMMONWEALTH OF AUSTRALIA

PATENT'S ACT 1952

APPLICATION FOR A STANDARD PATENT

73732/87

We, BARRY WRIGHT CORPORATION, a Corporation incorporated under the laws of the State of Massachusetts, U.S.A., of One Newton Executive Park, Newton Lower Falls, Massachusetts 02162, U.S.A., hereby apply for the grant of a Standard Patent for an invention

entitled:-

"OVERLOAD PROTECTION DEVICE"

which is described in the accompanying Complete Specification.

Details of basic application:-

Number: 873,619

Country: U.S.A.

Date: 12th June, 1986

FEE STAMP TO VALUE OF
\$335.00 ATTACHED
MAIL OFFICER: [Signature]

Our address for service is:

SHELSTON WATERS
55 Clarence Street
SYDNEY, N.S.W. 2000.

DATED this 2nd day of June, 1987

BARRY WRIGHT CORPORATION

COMMONWEALTH OF AUSTRALIA PATENTS ACT, 1952-1973
DECLARATION IN SUPPORT OF A CONVENTION APPLICATION FOR A PATENT

In support of the Convention Application No. 73732/87 made

(a) Here Insert (In full) Name of Company.

by (a) Barry Wright Corporation

(hereinafter referred to as "Applicant") for a patent for an invention entitled:

(b) Here Insert Title of Invention.

(b) OVERLOAD PROTECTION DEVICE

(c) Milton E. Gilbert

(c) and (d) Here Insert Full Name and Address of Company Official authorised to make declaration.

of (d) One Newton Executive Park, New Lower Falls, Massachusetts 02162, United States of America

do solemnly and sincerely declare as follows:

1. I am authorised by Applicant to make this declaration on its behalf.

2. The basic Application(s) as defined by section 141 of the Act was/were made in (e) U.S.A. (873,619) on the 12th day of June 1986

(e) Here Insert Basic Country or Countries followed by date or dates of Basic Application(s).

by (f) Laurence D. Chin, Christopher John Hiscock and Wayne Hans Domeier

(f) Here Insert Full Name(s) of Applicant(s) in Basic Country.

3. (g) Laurence D. Chin, Christopher John Hiscock Domeier and Wayne Hans Domeier of 64 Bonad Lane, West Newton, Massachusetts 02156, 36 Marlboro Road, Georgetown, Massachusetts 01833 and 311 Huntington Avenue, #3A, Boston, Massachusetts

(g) Here Insert (In full) Name and Address of actual Inventor or Inventors.

02115, U.S.A. the actual Inventor(s) of the invention and the facts upon which Applicant is entitled to make the Application are as follows:

Applicant is the Assignee of the said Inventor(s).

4. The basic Application(s) referred to in paragraph 2 of this Declaration was/were the first Application(s) made in a Convention country in respect of the invention, the subject of the Application.

DECLARED at Newton Lower Falls, Massachusetts 02162 USA this 13th day of August 1987.

(h)

Handwritten signature of Milton E. Gilbert

(Signature of Declarant)

Typed Name Milton E. Gilbert

Title Vice President General Counsel

To THE COMMISSIONER OF PATENTS.

(57) Claim

1. An overload protector adapted to be secured between a robot arm and a tool, comprising:

a cylinder having a central axis, an open end and a closed end,

a floating piston located within the cylinder and having a central axis,

a plurality of electromagnetic sensors for generating an electronic signal proportional to the strength of the sensed electromagnetic field secured to the cylinder and equally spaced, angularly, relative to the cylinder axis,

a magnet for generating an electromagnetic field associated with each sensor, the magnets being secured to the piston and equally spaced, angularly, relative to the piston axis,

(11) AU-B-73732/87
(10) 595038

-2-

means for pressurizing the closed end of the cylinder to move the piston toward the open end,

means to limit the movement of the piston toward the open end of the cylinder at a position where the magnets and the sensors are coincident, and

means responsive to the electronic signals from the sensors for depressurizing the cylinder when the piston and cylinder are moved relative to each other and the piston moves toward the closed end of the cylinder and the magnets and the sensors are moved out of coincidence and the resultant relative movement between at least one magnet and its associated sensor cause a signal to be generated by at least one of the sensors to deviate substantially from a predetermined value.

OVERLOAD PROTECTION DEVICE

Field of the Invention

05 This invention relates to overload protection devices and, more particularly, to devices designed to sense process disruptions which occur at the end of arm tooling in robotic automated machinery and interrupt the process.

Background of the Invention

10 In the field of robotics a need has been recognized for mechanism which will automatically sense process disruptions as, for example, excessive forces and inadvertent physical contacts with the end of the arm tooling of robots and interrupt the process. It has likewise been determined that there is a need for protecting not only the robot but the tooling from damage if a disruption occurs in a process.

15 Many such devices have been developed. One such device is known as a "breakaway" joint. This type of joint is interposed between the tooling and the robot arm and physically breaks if an overload force greater than a predetermined amount is applied between the robot and the tooling. Such joints are difficult to replace and are not always reliable in protecting the robot and/or the tooling from damage. In most cases, such breakaway joints may only be used once and must be discarded and replaced with a new one.

Another type of protective device is known as a "snapaway" joint. When the robot or the tooling encounters a disruption, such as striking a misplaced part, the device actually snaps out of place displacing the tooling or allowing it to yield from contact with whatever it struck. For the most part, these devices embody releasable springs which yield when a predetermined load is placed upon them. Subsequently, they snap back after the disruption has been corrected. Many such devices use ball detent mechanisms. The range of such devices is limited by the strength of the springs employed, which is relatively low, and their ability to return to their original set position.

While the above described mechanisms are designed to unlock the rigid connection between the robot arm and its tooling, few, if any, are equipped to either shut down the process completely to prevent further spoilage of workpieces or to allow the robot to be reset with minimal downtime.

Consequently, a need exists for an overload protective device which will prevent or minimize damage to the workpiece or tooling upon the detection of a disruption and which will allow the process to be restarted in a minimal amount of time while retaining a high degree of tooling repeatability. Such a device should be adjustable to account for a wide range of loads and should be universally adaptable to tooling of various kinds.

Summary of the Invention

According to the invention, there is provided an overload protector adapted to be secured between a robot arm and a tool, comprising:

a cylinder having a central axis, an open end and a closed end,

a floating piston located within the cylinder and having a central axis,

10 a plurality of electromagnetic sensors for generating an electronic signal proportional to the strength of the sensed electromagnetic field secured to the cylinder and equally spaced, angularly, relative to the cylinder axis,

a magnet for generating an electromagnetic field associated with each sensor, the magnets being secured to the piston and equally spaced, angularly, relative to the piston axis,

means for pressurizing the closed end of the cylinder to move the piston toward the open end,

20 means to limit the movement of the piston toward the open end of the cylinder at a position where the magnets and the sensors are coincident, and

means responsive to the electronic signals from the sensors for depressurizing the cylinder when the piston and cylinder are moved relative to each other and the piston moves toward the closed end of the cylinder and the magnets and the sensors are moved out of coincidence and the resultant relative movement between at least one magnet and its associated sensor cause a signal to be generated by at least one of the sensors to deviate substantially from a predetermined value.

10 In a preferred embodiment, would be provided also guide means extending parallel to its axis, which means are engaged by releasable, adjustable detents, which extend from the cylinder to the guide means. This assures that each magnet is aligned angularly with its associated sensor. The releasable detents also serve in resetting the piston and cylinder after a disruption has occurred and the cylinder has become depressurized.

When a rotational force causes the piston and cylinder to rotate relative to each other of a magnitude sufficient to overcome the force of the detents, the magnets and sensors experience relative motion and at least one of the sensors generates an overload signal to

cause depressurization. Likewise, when a tilting motion occurs between the piston and the cylinder sufficient to overcome the predetermined pressure in the cylinder, the coincident axis of the piston and the cylinder will be displaced from each other and, again, there will be relative motion between at least one magnet and its associated sensor causing a signal to be generated by the sensor to trigger depressurization of the cylinder.

10 Furthermore, in the preferred embodiment, the cylinder is depressurized by energizing a solenoid valve which closes an input air valve to the cylinder and opens an exhaust channel to the piston chamber. This causes the diaphragm to become limp permitting a predetermined amount of compliance between the robot arm and the tool; thereby preventing further damage to the tool or workpiece.

The above and other features of the invention, including various and novel details of construction and combinations of parts, will now be more particularly described with reference to the accompanying drawings and pointed out in the claims. It will be understood that the particular overload protection device embodying the invention is shown by way of illustration only and as a limitation of the invention. The principles and features of this invention may be employed in varied and numerous embodiments without departing from the scope of the invention.

Brief Description of the Drawings

Figure 1 is a perspective view of an overload protection device secured between a robot arm and a tool.

05 Figure 2 is an elevational view partially in section and with parts broken away of the overload protection device.

Figure 3 is a sectional view in elevation of the overload protection device.

10 Figure 4 is a side view of the main portion of the piston.

Figure 5 is a bottom plan view, thereof.

Figure 6 is a top plan view, thereof.

15 Figure 7 is a sectional view taken along the line VII-VII on Figure 6.

Figure 8 is a side view, partially broken away, of the tooling interface of the overload protector.

Figure 9 is a top plan view, thereof.

Figure 10 is a bottom plan view, thereof.

20 Figure 11 is a side view, partially broken away, of a mounting plate for the overload protector.

Figure 12 is a top plan view, thereof.

25 Figure 13 is a side view, partially broken away and in section, of the retaining cap of the overload protector.

Figure 14 is a top plan view, thereof.

15 Figure 26 is a section taken along the lines XXVI-XXVI on Figure 24.

Figure 27 is a schematic of the electronic system of the invention.

20 Figure 28 is a waveform timing diagram illustrating the timing of certain functions in Figure 27.

Detailed Description of the Invention

25 Figure 1 discloses an overload protector 10 made in accordance with this invention secured between a robot arm 12 and a tool 14. A tool interface member 16 attaches the overload protector to the tool and a mounting plate 70 attaches the protector to the robot arm.

Referring next to Figures 2 and 3, the overload protector 10 is shown in assembled form, but inverted with respect to the Figure 1 showing, with the tool interface 16 projecting upwardly. The device, in its elemental form, comprises a cylinder 18 and a floating piston 20. The tool interface 16 is integral with the piston and projects out of the cylinder. The cylinder is made up of a number of components, including a top retaining cap 22, a valve enclosure 24, and a sensor ring 26.

The piston comprises a main piston body 28, also known as a diaphragm ring, and the tooling interface 16 which is secured to the main piston body 28, as seen in Figure 2. The elements of the cylinder 18 are assembled around the piston, as will be explained in more detail hereinafter.

The cylinder has a central axis, A_c , a closed end 30 formed by the bottom of the valve enclosure 24, and a open end defined by a circular opening 32 in the top retaining cap 22. A Bellofram diaphragm 33 is located between the main piston body 20 and the closed end 30 of the cylinder. Upon assembly, the diaphragm is firmly clamped between the retaining cap 22 and the valve enclosure 24. An annular step 34 in the valve enclosure mates with a concentric annular flange 36 on the retaining cap 22 with the periphery of the diaphragm lying within, and not visible from, the outside of the cylinder.

The Piston

A - The Main Portion

Referring now to Figures 4 through 7, the piston will be described. The main portion 28 of the piston is engagable with the top of the Bellofram diaphragm 33 and is also, therefore, called the diaphragm ring. It is circular in configuration having a central axis A_p . A plurality of magnets 40 are located in the piston extending to its circumference. There are 3 magnets spaced 120 degrees equidistantly from each other, angularly, relative to the central axis A_p . The magnets lie in a common plane P_m which is normal to the axis A_p . Formed in the circumference of the piston are guide means in the form of V-shaped grooves 42 which are parallel to the axis A_p of the piston.

Upwardly projecting V-shaped detents 44 are formed on the piston in alignment above the magnets 40. A circular receiving well or recess 46 is formed in the upper surface of the piston to receive the lower cylindrical portion 47 of the tooling interface, as shown in Figures 2 and 3. The upper portion of the piston includes a conical surface 48 which mates with a similar conical surface 50 on the retaining cap 22 which will be explained in greater detail hereinafter. Three bolt holes 51 are formed in the piston to receive bolts 52 (Figure 2) to secure it to the tooling interface 16.

B - The Tool Interface

05 The tool interface 16, which is joined to the
piston 28, is shown in Figures 8, 9, and 10. It
includes tapped bolt holes 54 in its bottom surface
for receiving the bolts 52. The upper portion of
the tool interface includes a circular flange 56
having a first set of tapped holes 58 for securing
the interface member 16 to a robot tool and a second
10 set of tapped holes 60 for securing the interface to
a tool of smaller size. Dowel pin holes 62 and 64
are formed in the flange to assist in the assembly
of the interface and the tool.

The Mounting Plate

15 A mounting plate 70 is employed for securing
the overload protector to the robot arm and will be
described with reference to Figures 11 and 12. It
is a flat circular plate having a circular well 72
for receiving and locating a downwardly projecting
cylindrical member 74 (Figure 19) formed on the
20 valve encloser 24. The plate 70 includes counter-
sunk holes 75 for receiving bolts which thread into
the robot arm and six tapped holes 76 for receiving
bolts which pass through holes in the retaining cap
and in the valve encloser. Dowel pin holes 84 are
25 also included in the mounting plate 70 to assist in
assembly.

The Cylinder Assembly

A - Retaining Cap

05 The retaining cap 22 defines the open end of
the cylinder assembly and will be described with
reference to Figures 13 to 18. It is generally
cylindrical in cross section having a circular
opening 32 through which the tooling interface
portion 16 of the piston 20 projects. It includes
the conical surface 50 which mates with the conical
10 surface 48 on the main body 28 of the piston. The
function of the conical surfaces 48 and 50 is to
limit the amount of the travel of the piston in a
direction away from the closed end and to align the
common planes of the magnets with the common planes
15 of the sensors. They also serve to align the axis
 A_p of the piston with the axis A_c of the cylinder.

20 Three bores 88 are formed equidistantly, 120° ,
from each other and in a common plane, in the
retaining cap 22. Each receives a spring biased
detent 90 (Figure 3) in the form of an adjustable
Vlier spring plunger which projects through the
sensor ring 26 and engages the V-shaped grooves 42
in the piston 28. The function of the detents will
be explained in greater detail hereinafter.

25 Three V-shaped indentations 92 are spaced 120°
apart in an annular, horizontal surface 94 which is
essentially the top of the cylinder. The V-shaped
projections 44 on the piston 28 are engagable within
the V-shaped indentations 92 in the cylinder and
30 serve as aligning means for resetting the piston in
the cylinder after a disruption occurs.

05 A chamber 96 (Figures 14 and 18) is formed in the cap 22 and communicates with an oval-shaped opening 98 in the wall of the cap. The electrical connectors to the overload protections device enter through the oval orifice 98 and strain relief means (not shown) are located in the chamber 96.

10 A plurality of tapped holes 100 are formed in the bottom of the cap to receive bolts projecting upwardly through counterbored holes 101 in the valve enclosure 24. On assembly, the diaphragm 33 is positioned between the cap 22 and the valve enclosure 24 (Figures 2 and 3) and its edges are clamped tightly by bolts passing through holes 102 in the valve enclosure 24 (see Figure 21).

15 B - The Valve Encloser

20 The valve encloser 24 which forms the closed end of the cylinder 30 will next be described with reference to Figures 19 through 22. It includes a circular recess 108 which is the closed end 30 of the cylinder. It includes the circular projection 74 which is received in the well 72 in the mounting plate 70.

25 A passageway 110 is formed in the wall of the encloser, through which an appropriate valve fitting (not shown), admits pressurized air to and from the cylinder. The encloser 24 also includes a dowel pin hole 112 to assist in assembly with the mounting plate 70. Six bolt clearance holes 84 mate with the six bolt clearance holes 82 in the retaining cap 22

and receive bolts 83 which are threaded into the mounting plate 70 (Figure 2).

The Sensor Ring

05 The sensor ring 26 will now be described with reference to Figures 23 to 26. The principal purpose of the sensor ring 26 is to mount the Hall effect sensors and their wiring in relation to the magnets 40 in floating piston 20. The sensor comprises a circular ring 120 formed with three
10 flats 122 equidistantly spaced 120° apart. A Hall effect sensor 124 is positioned on each flat, only one being shown in Figure 24.

15 In the center of each flat 122, there is an opening 126 in front of the sensor 124 so that there will be no obstruction to the magnetic field between the sensor and its associated magnet (not shown in Figure 24) but which is located on the piston in alignment with the sensor. Also formed in the
20 sensor ring are three openings 128 through which the spring plungers 90 pass, as seen in Figure 2. An annular channel 130 is formed around the ring to accommodate the wiring from the sensors.

The Piston-Cylinder Assembly

25 The overload protection device is assembled, as shown in Figures 2 and 3. The tooling interface portion 16 of the piston 20 is secured to the main body portion 28. The magnets 40 (See Figure 6) are secured in the main body of the piston.

The cylinder is assembled initially without the mounting plate 70 by first positioning the piston within the retaining cap 22. The diaphragm 33 is next positioned beneath the piston with its perimeter between the retaining cap and the valve enclosure 24 forming an airtight seal. The valve enclosure and the retaining cap are then bolted together and the combination is then bolted onto the mounting plate.

Operation

With the tooling interface 16 secured to the tool 14 and the cylinder secured to the robot arm 12, as seen in Figure 1, the tool and the arm are rotated relative to one another until the detents 90 (Figure 2) engage the longitudinal grooves 42 (Figure 6) in the piston. The cylinder is then pressurized causing the piston to move toward the open end of the cylinder until the detents 44 spaced around the top of the piston engage the depressions 92 in the retaining cap. The conical surface 48 on the piston engages the mating conical surface 50 on the retaining cap. This engagement serves to align the axis A_p of the piston with the axis A_c of the cylinder in coincidence and to limit the amount of movement of the piston in the direction toward the open end of the cylinder, or upwardly as viewed in Figures 2 and 3. The force by which the detents 90 engage the grooves 42 in the piston are adjusted to a predetermined amount which is the force by which the piston and the cylinder will have to rotate

relative to each other upon the occurrence of a disruption to cause the magnets and sensors to move relative to each other.

05 The overload protector will respond to three general types of relative movement between the robot arm and its tool. Linear motion along the axis A_p of the piston and A_c of the cylinder, rotational motion about these axes, when they are coincident, and motion which is a rocking or tilting motion
10 which would cause the axes to move out of coincidence results in a signal to be generated.

If a force resulting from a disruption is applied in a direction axially of the then coincident axis A_p and A_c of the piston and cylinder
15 respectfully, which is sufficient to overcome the predetermined pressure within the cylinder, the piston and cylinder move relative to each other. The piston moves toward the closed end of the cylinder resulting in relative movement between one or more sensors and its associated magnet. At this
20 time, the common planes P_s and P_m of the sensors and the magnets respectively, which were coincident, move apart. Again, the resulting movement of one of the magnets relative to its associated sensor, causes a signal to be generated by the sensor
25 causing the cylinder to be depressurized and the diaphragm to become limp resulting in a compliant coupling existing between the robot and the tooling.

30 If a rotational movement takes place between the tool and the robot arm due to a disruption of a

05 magnitude sufficient to overcome the force of the
Vlier spring plunges urging the detents into the
grooves of the piston, relative rotational motion
will take place between the sensors and their
associated magnets. Again, this results in de-
pressurizing the cylinder. If a force, which is a
combination of linear and rotational results in a
tilting motion to move the coincident axes of the
cylinder and piston out of coincidence, there will,
10 again, be relative motion between one or more of the
sensors and its associated magnet. Thus, as a
result of any relative motion between a sensor and
its magnet, there is a change in the magnetic field
and the sensor is actuated.

15 Upon depressurization of the cylinder, the
piston and cylinder may be returned to their
operating state manually by re-engaging the detents
with the guide slots in the piston and again
pressurizing the cylinder.

20 The Electronic System

The overall circuit diagram of the electronic
system of the invention is shown in Figure 27.
Major blocks of the apparatus of Figure 27 are shown
within dotted lines, and comprise a sensor circuit
25 210, a reference adjust circuit 228, a detector
circuit 212, an overload indicator 224, a control
circuit 214, a Ready-Not Ready indicator 226, a
pneumatic valve circuit 218 and robot output
circuitry 216.

The sensor circuit is made up of the three Hall effect sensors H_1 , H_2 , and H_3 , previously mentioned in connection with the overload protection device. These sensors are located on a cylinder adjacent
05 oppositely disposed magnets mounted on the piston of the overload protection device. Hall effect sensors H_1 , H_2 and H_3 generate a current signal, I_1 , I_2 or I_3 , respectively, which causes a voltage to occur at the negative input lead of respective comparators 1,
10 2 or 3, located in detector circuit 212. The voltage applied to the comparators 1, 2 or 3 is dependent on the IR drop across fixed matched resistors R_1 , R_2 or R_3 , respectively.

When the sensors H_1 , H_2 and H_3 are located in a
15 null position, such that no overload condition exists, the voltage at the negative input leads to comparators 1, 2 and 3 will be substantially identical and will be at a predetermined level indicative of a null condition, such as, 6 volts
20 positive. The voltage at the positive input lead to comparators 1, 2 and 3 is set by variable voltage resistors V_1 , V_2 and V_3 , respectively, coupled between ground and a $B+$ power supply voltage of, for example, 12 volts DC.

25 Variable resistors V_1 , V_2 and V_3 provide a reference adjust circuit 228 whereby the sensitivity of the electronic circuitry of Figure 27 can be adjusted so that very small changes in the relative position between any of sensors H_1 , H_2 and H_3 and
30 their corresponding magnet, will produce a

sufficient voltage difference between the plus and negative inputs to comparators 1, 2 or 3 to generate an output pulse from one of the output leads of comparators 1, 2 or 3 which are tied together and
05 coupled to the Set input terminal of NAND Gate N1 in the control circuit 214.

An overload protection device logic diagram is provided below as Table I showing the logic states at various circuit locations numbered within a
10 pointed box in Figure 27 as a result of certain occurrences.

TABLE 1

OPD LOGIC DIAGRAM

Event Description	- - - - -Logic Locations- - - - -										
	1	2	3	4	5	6	7	8	9	D4	D1
"ON" State	L	H	H	L	L	L	H	L	H	GRN	OFF
Overload Detected	<u>H</u>	<u>L</u>	<u>L</u>	<u>H</u>	<u>H</u>	<u>H</u>	<u>H</u>	<u>H</u>	<u>L</u>	<u>Red</u>	<u>ON</u>
one sec. later	H	L	L	H	H	<u>L</u>	H	<u>L</u>	<u>H</u>	Red	ON
"Reset" switch	H	L	L	H	H	L	<u>L</u>	<u>H</u>	<u>L</u>	Red	ON
Manual reset	<u>L</u>	<u>H</u>	<u>H</u>	<u>L</u>	H	L	L	H	L	Red	<u>OFF</u>
"ON"	L	H	H	L	<u>L</u>	L	<u>H</u>	<u>L</u>	<u>H</u>	<u>GRN</u>	OFF

Notes: 1) " " below a letter indicates a change of state with that event.

Thus, when an overload condition is present, as shown in the logic diagram of Table I above, the following conditions exist with respect to the logic states at the negative inputs to comparators 1, 2 or 3. This point goes from a normal "ON" state of a Low voltage to a High (See logic location 1). When this occurs, the logic state at logic location 2, i.e., the input to the Set(S) terminal of NAND Gate N1, changes from a High to a Low. This sets a flip-flop circuit comprising NAND Gates N1 and N2 resulting in the output of N2 (at logic location 3) going from a High to a Low. This Low is coupled to the second terminal of NAND Gate N1 and also to the second terminal of NAND Gate N3, the purpose of which will be described later.

The change in logic level from High to Low caused by the overload detection which occurs at the output of the comparators (logic location 2) is also coupled via filter capacitor C1 to the emitter of transistor Q1 causing Q1 to conduct from ground through LED D1 through the collector to the base of Q1 through bias resistors R5 and resistor R20 to a power supply voltage of 5 volts. Biasing resistor R4 is coupled to B+ and the collector of Q1 at the junction of the anode of LED D1. Thus, LED D1 is illuminated and stays illuminated as long as the output of any of the comparators is at a Low or, in other words, whenever the negative inputs to any of the comparators is at a High, indicating that an overload condition has occurred (See OPT Logic

Diagram Table 1). The Low signal at logic location 2 is also coupled to NAND Gate N3 causing the output of NAND Gate 3 to go from a Low to a High (See logic location 4 in the Logic Diagram of Table I). This
05 High voltage signal is applied across resistor R15 and causes transistor Q6 to conduct thereby providing a current path from ground through the emitter of Q1 and coil L1 of a solenoid valve, which is connected to B+ and is coupled in parallel with
10 unilateral diode D3. This causes a pneumatic valve to operate which cuts off the source of air to the overload protection device cylinder and opens the exhaust for the piston causing the diaphragm in the overload detection device to deflate thereby
15 resulting in compliant coupling between the robot arm and the robot tool.

The output of NAND Gate 2 (logic location 3) is coupled through capacitor C2 to the input of a timer circuit T1. T1 is a programmable timer, such as an
20 LM 555 chip. T1 includes a flip-flop circuit which is "Set" when the signal at logic level point 3 goes from a High to a Low. Timer T1 produces a High pulse of fixed duration, i.e., one second, which is coupled to the input of NAND Gate 7 (logic location
25 6). This High at NAND Gate 7 is coupled to one input lead of NAND Gate 8 the other input of which is floating until grounded in the re-set position of S1. The output of NAND Gate 8 is also High at this point (logic Location 8), which causes grounded
30 emitter transistor Q5 to start conducting. When Q5

conducts, then Q4, is also biased to conduct, energizing solenoid relay L2 coupled in parallel with unilateral conducting diode D2. Solenoid relay L2 moves relay switches as from the normally closed position NC to a normally open position NO; opening the robot load circuit turning the robot off for the one second duration of the timer pulse from T1. This alerts the robot operator to the existence of an overload condition.

In an alternative configuration of the interface circuit to the robot, the robot load may be connected to ground via a current sink transistor Q3, the emitter of which is coupled to ground, or through a current source configuration of transistor Q2 in which the collector is coupled to B+. In normal operating conditions, Q2 would provide current source to energize the robot, whereas Q3 would provide a ground to maintain the robot energized. In either configuration, when Q5 conducts, because of the presence of a High from output of NAND Gate 8, (logic location 9) Q2 and the Q3 both stop conducting, thereby de-energizing the robot momentarily, as shown in Figure 28 for the time interval t_0-t_1 .

At the end of the one second interval, "one second later" Table 1, the input goes Low to NAND Gate 7 and the robot is re-energized. However, the robot operator has been notified by this 1 second de-energization that something is wrong with respect

to the operation of the robot arm and that any obstruction should therefore be cleared.

When an obstruction is cleared, the reset switch S1 is moved from the On position, as shown, to the Reset position. As may be seen in the Reset position, the reset input terminal to NAND Gate N2 is grounded causing the output state of NAND Gate 2 at logic location point 7 to go from a High to a Low. Similarly, by turning S1 from On to Reset, one of the input leads to NAND Gate N8 is also grounded causing the output of NAND Gate N8 at logic location 8 to go from a Low to a High, which in turn, causes the junction of R12, R13 and the base of Q5 to go from a High to a Low, thereby re-energizing the robot since Q3 then becomes conductive again and Q2 also becomes conductive again, whereas Q4 becomes non-conductive, de-energizing solenoid relay L2 causing the relay contacts to go to their normally closed position, as shown.

It should be noted that once an overload condition occurs, an indicator light in circuit 226 is illuminated. The Ready-Not Ready indicator lamp circuit 226 operation will now be described. A single LED D4 capable of emitting red or green light is utilized. For illustrative purposes LED D4 is shown as two diodes, a red LED R and a green LED G connected back-to-back between NPN transistor Q8 and PNP transistor Q7 suitably biased by resistors R17 and R16 coupled to +5 volts. When the output of NAND Gate N5 (location 5) goes from a Low to a High, the red diode R of D4 goes On indicating a Not Ready

state and the green ready diode G goes Off. A High at the juncture of R19 and R18 biases Q7 "On" causing current to flow from ground through Q8 through LED R through Q7 to R16 and +5 volts.

05 Whereas when the opposite condition obtains Q7 conducts enabling current to flow through Q7 and green diode G through R17 to +5 volts while Q8 is biased "Off".

10 Once the robot has been de-energized as above, the cause of the overload may be fixed while the diaphragm is deflated. Then, the overload protection device may be reset to its null position or non-overload initial state by switching S1 to the "RESET" position. In the "RESET" position of S1, 15 the Re-Set input to N2 is grounded causing the input (logic location 7) to go LOW. The output does not change, however, until the other input terminal connected to the in terminal S put of NAND Gate N1 goes LOW when the OPD is manually reset to its null. 20 (See Manual Reset line of Table 1) Also, one input to NAND Gate 8 goes LOW causing its output to go HIGH. A HIGH at location 8 de-energizes the robot as described above. When the overload protection device is manually reset, next switch S1 may be put 25 back into its "On" position. At this time, provided there is no overload and the overload protective device has been manually aligned and reset, the signals at all of the negative inputs to comparators 1, 2 or 3 will now be at a Low. The output of the 30 comparators at logic point 2 will then revert to a

THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:-

1. An overload protector adapted to be secured between a robot arm and a tool, comprising:

a cylinder having a central axis, an open end and a closed end,

a floating piston located within the cylinder and having a central axis,

a plurality of electromagnetic sensors for generating an electronic signal proportional to the strength of the sensed electromagnetic field secured to the cylinder and equally spaced, angularly, relative to the cylinder axis,

10

a magnet for generating an electromagnetic field associated with each sensor, the magnets being secured to the piston and equally spaced, angularly, relative to the piston axis,

means for pressurizing the closed end of the cylinder to move the piston toward the open end,

means to limit the movement of the piston toward the open end of the cylinder at a position where the magnets and the sensors are coincident, and

20

means responsive to the electronic signals from the sensors for depressurizing the cylinder when the piston and cylinder are moved relative to each other and the piston moves toward the closed end of the cylinder and the magnets and the sensors are moved out of coincidence and the resultant relative movement between at least one

magnet and its associated sensor cause a signal to be generated by at least one of the sensors to deviate substantially from a predetermined value.

2. An overload protector according to claim 1, additionally comprising:

guide means on the piston extending parallel to the piston axis,

releasable detent means extending from the cylinder to the guide means on the piston to align each magnet angularly with its associated sensor, and

means responsive to the electronic signals from the sensors for depressurizing the cylinder when the piston and the cylinder are rotated relative to each other by a force sufficient to displace the detent means relative to the guide means and the resultant relative movement between at least one magnet and its associated sensor causes a signal to be generated by the sensor.

3. An overload protector according to claim 1, additionally comprising:

means to align the axis of the piston in coincidence with the axis of the cylinder and to position the magnets in coincidence with the sensors when the cylinder is pressurized, and

means responsive to the electronic signals from the sensors for depressurizing the cylinder when the piston and the cylinder are displaced relative to each other and the axis of the piston and the axis of the cylinder are

displaced out of coincidence and the resultant relative movement between at least one magnet and its associated sensor causes a signal to be generated by the sensor.

4. An overload protection device according to any one of claims 1 to 3 wherein the means to limit the movement of the piston comprises conical mating surfaces on the piston and/or the cylinder adjacent the open end.

5. An overload protection device according to claim 2 wherein the releasable detent means is adjustable to vary the force with which it engages the guide means.

6. An overload protection device according to claim 2 wherein the guide means comprises V-shaped grooves in the piston.

7. An overload protection device according to claim 3 wherein the means to align the axis of the piston in coincidence with the axis of the cylinder, comprises angularly spaced projections and indentations on the piston and the cylinder.

8. An overload protection device according to any one of the previous claims, wherein a diaphragm separates the piston from the closed end of the cylinder.

9. An overload protection device substantially as herein described with reference to the accompanying drawings.
