(54) **Title:** HUMANIZED ANTI-α9 INTEGRIN ANTIBODIES AND THE USES THEREOF

(57) **Abstract:** The present invention provides humanized antibodies that immunospecifically recognize human α9 integrin. Some of these antibodies inhibit the biological functions of the α9 integrin, thereby exhibiting therapeutic effects on various disorders or diseases that are associated with α9 integrin, including cancer, e.g., the growth and metastasis of a cancer cell, and inflammatory diseases, e.g., rheumatoid arthritis, osteoarthritis, hepatitis, bronchial asthma, fibrosis, diabetes, arteriosclerosis, multiple sclerosis, granuloma, an inflammatory bowel disease (ulcerative colitis and Crohn's disease), an autoimmune disease, and so forth.

DESCRIPTION

HUMANIZED ANTI-α9 INTEGRIN ANTIBODIES AND THE USES THEREOF

5

1. FIELD OF THE INVENTION

The present invention relates to humanized antibodies that immunospecifically recognize human α9 integrin and to their therapeutic and diagnostic uses for various diseases or disorders that are associated with or involve

10   α9 integrin, including cancer, inflammatory diseases, autoimmune diseases, and the like.

2. BACKGROUND OF THE INVENTION

Cells adhere to extracellular matrix (hereinafter abbreviated as ECM)

15   mediated by a group of cell surface receptors which are termed integrins.   Integrins perform their functions by forming 1 : 1 heterodimers of α and β chains.   At least 18 types of α chain, 8 types of β chain and 24 types of αβ heterodimer have been identified and confirmed so far.   It is known that each integrin recognizes a specific ligand.   Integrins are classified into subfamilies depending upon their ligand

20   specificities or functions, and divided into collagen receptors, laminin receptors, RGD receptors recognizing an Arg-Gly-Asp (RGD) sequence present in fibronectin, vitronectin, etc., and leukocyte-specific receptors present only in leukocytes (Hynes, R. O., 2002, Integrins: Bidirectional, Allosteric Signaling Machines. *Cell* 110: 673-87; Miyasaka, M., 2000, New edition of *Adhesion Molecule Handbook*,

25   Shujunsya).   The α4 and α9 integrins are members of a subfamily that does not belong to any of these types and called the α4 integrin subfamily (Elise L. Palmer, Curzio Rfiegg, Ronald Ferrando, Robert Pytela, Sheppard D., 1993, Sequence and Tissue Distribution of the Integrin α9 Subunit, a Novel Partner of β1 That Is Widely Distributed in Epithelia and Muscle. *The Journal of Cell Biology*, 123: 1289-97).

30   Meanwhile, ECM used to be considered so far to serve as a mere cementing substance between cells.   It has now become clear that the integrin-mediated ECM-cell interaction is significantly involved in regulating the growth, adhesion, movement, etc. of cells and associated with the onset of diseases including a

progression of cancer, an exacerbation of inflammation, and the like.

For example, osteopontin (hereinafter abbreviated as OPN) which is one of the ECMs is a secreted, acidic phosphorylated glycoprotein with a molecular weight of about 41 kDa and is a molecule, whose expression is widely observed in breast milk, urine, renal tubules, osteoclasts, osteoblasts, macrophages, activated T cells, tumor tissues, and so forth.   OPN has the adhesion sequences, GRGDS (SEQ ID NO:1) at the center of its molecule, the SVVYGLR (SEQ ID NO:2) sequence in human OPN or the SLAYGLR (SEQ ID NO:3) sequence in mouse OPN, and a thrombin-cleavage site in close proximity thereto, and binds through the GRGDS (SEQ ID NO:1) sequence to the RGD integrin or to the $\alpha 4$ ($\alpha 4\beta 1$) and $\alpha 9$ ($\alpha 9\beta 1$) integrins through the SVVYGLR (SEQ ID NO:2) sequence or the SLAYGLR (SEQ ID NO:3) sequence.

WO 02/081522 discloses a therapeutic effect on rheumatoid arthritis or hepatitis by inhibiting the OPN functions using OPN knockout mice or neutralizing antibodies against OPN.   Moreover, this publication discloses that the SVVYGLR (SEQ ID NO:2) sequence is essential as recognizing the $\alpha 9$ and $\alpha 4$ integrins for pathogenesis of an inflammatory disease and that receptors for OPN are expressed in immunocompetent cells or the like and associated with an inflammatory disease.

Differences in binding profile have been found in that $\alpha 4\beta 1$ binds both to OPN not cleaved with thrombin (uncleaved OPN) and to the N-terminal fragment of thrombin-cleaved OPN (cleaved OPN), whereas $\alpha 9\beta 1$ binds only to the cleaved OPN (Y. Yokosaki, et al., (1999) *The Journal of Biological Chemistry,* 274: 36328-36334; P. M. Green, et al., (2001) *FEBS Letters,* 503: 75-79; S. T. Barry, et al., (2000) *Experimental Cell Research,* 258: 342-351).

The $\alpha 4$ and $\alpha 9$ integrins share many common ligands other than OPN. Known ligands are the EDA domain of fibronectin, propeptide-von Willebrand factor (pp-vWF), tissue transglutaminase (tTG), blood coagulation factor XIII, vascular cell adhesion molecule-1(VCAM-1), etc.   In addition, the CS-1 domain of fibronectin, MadCAM-1 ($\alpha 4\beta 7$), etc. are known as the ligands specifically recognized by the $\alpha 4$ integrin.   Tenascin-C, plasmin, etc. are known as the ligands specifically recognized by the $\alpha 9$ integrin.

The amino acid sequences for the integrin subunits $\alpha 9$, $\alpha 4$ and $\beta 1$ are

publicly known.   For instance, human α9 is registered as NM_002207, mouse α9 as NM_133721, human α4 as NM_000885, mouse α4 as NM_010576, human β1 as X07979, and mouse β1 as NM_010578, at the GenBank.   These integrins are also known to have high similarities between species in amino acid sequence.

5

3.   SUMMARY OF THE INVENTION

While a variety of drugs are known at present for the treatment of cancer, inflammatory diseases and autoimmune diseases, it has been desired to develop a preventive and/or therapeutic agent, etc. having more improved therapeutic effects on
10   cancer, inflammatory diseases and autoimmune diseases.   The present invention is based, in part, on the discovery by the present inventors that a specific inhibitory antibody against the α9 integrin has cancer-suppressing and anti-inflammatory effects.

Previously, the present inventors isolated mouse monoclonal antibodies that
15   immunospecifically recognize human α9 integrin and are produced by hybridoma clones, 1K11, 21C5, 24I11, 25B6 and 28S1 (Depository Accession Nos. FERM BP-10510, FERM BP-10511, FERM BP-10512, FERM BP-10513 and FERM BP-10832, respectively), and those that immunospecifically recognize mouse α9 integrin and are produced by hybridoma clones, 18R18D, 12C4'58, 11L2B and
20   55A2C (Depository Accession Nos. FERM ABP-10195, FERM ABP-10196, FERM ABP-10197 and FERM ABP-10198, respectively).   Herein, the hybridoma clone designations are interchangeably used as the designations of the monoclonal antibodies produced by the clones.   All of these mouse anti-human α9 integrin antibodies were of IgG1 isotype.   Some of these monoclonal antibodies inhibit the
25   binding between human and/or mouse α9 integrin and a ligand of α9 integrin, such as osteopontin.   Thus, these anti-α9 integrin antibodies inhibit the α9 integrin functions and exhibit therapeutic effects on cancer, e.g., the growth or metastasis of cancer cells, and on inflammatory diseases, e.g., rheumatoid arthritis, osteoarthritis, hepatitis, bronchial asthma, fibrosis, diabetes mellitus, arteriosclerosis, multiple
30   sclerosis, granuloma, an inflammatory bowel disease (ulcerative colitis and Crohn's disease), an autoimmune disease, and the like.

Furthermore, the anti-α9 integrin antibodies of the present invention can be

used as an *in vivo* diagnostic agent to detect the presence and the level of α9 integrin expression in a subject, thereby diagnosing a disorder or a disease involving α9 integrin.

5   However, since these monoclonal antibodies are of mouse origin, possible adverse effects due to their immunogenicity in humans have hampered their direct applications to diagnostic or therapeutic uses in humans.   In order to reduce the immunogenicity, the present inventors have prepared a humanized antibody that have biological activities corresponding to those exhibited by the original mouse anti-α9 integrin antibody from which said humanized antibody was derived.

10   Accordingly, the present invention provides a humanized antibody or an antigen-binding fragment thereof, which immunospecifically recognizes human α9 integrin, said antibody comprising an antigen-binding region partially derived from a non-human origin and partially derived from a human origin.   In a specific embodiment, the humanized antibody or an antigen-binding fragment thereof of the

15   present invention comprises a complementarity determining region (CDR) derived from a non-human source (donor), such as 1K11, 21C5, 24I11, 25B6 and 28S1 monoclonal antibodies, and a framework region (FR) derived from a human source (acceptor).   In one embodiment, said humanized antibody or an antigen-binding fragment thereof inhibits the binding between human α9 integrin and a ligand of

20   human α9 integrin.

In a specific embodiment, said humanized antibody or an antigen-binding fragment thereof that immunospecifically recognizes human α9 integrin comprises: (i) a heavy chain (H-chain) comprising at least one H-chain FR (FRH) derived from a variable region (V-region) of a human H-chain, and at least one H-chain

25   complementarity determining region (CDRH) derived from at least one of the CDRHs of a non-human antibody that immunospecifically recognizes human α9 integrin; or (ii) a light chain (L-chain) comprising at least one L-chain FR (FRL) derived from a V-region of a human L-chain, and at least one L-chain complementarity determining region (CDRL) derived from at least one of the

30   CDRLs of a non-human antibody that immunospecifically recognizes human α9 integrin; or both (i) and (ii) above.   For example, said non-human antibody, from which at least one of the CDRHs and/or at least one of the CDRLs of the humanized

antibody of the invention is derived, is a monoclonal antibody produced by a hybridoma selected from the group consisting of Accession Nos. FERM BP-10510, FERM BP-10511, FERM BP-10512, FERM BP-10513 and FERM BP-10832.

In a preferred specific embodiment, the humanized antibody or an antigen-binding fragment thereof, of the present invention comprises: (i) at least one FRH derived from a human FRH, and at least one CDRH comprising an amino acid sequence selected from the group consisting of the amino acid sequences of SEQ ID NOS:4, 5 and 6; or (ii) at least one FRL derived from a human FRL, and at least one CDRL comprising an amino acid sequence selected from the group consisting of the amino acid sequences of SEQ ID NOS:11, 12 and 13; or (iii) both (i) and (ii) above. Said humanized antibody or an antigen-binding fragment thereof, of the present invention may comprise CDRH1, CDRH2 and CDRH3, which comprise the amino acid sequences of SEQ ID NOS:4, 5 and 6, respectively. In the alternative, said humanized antibody or an antigen-binding fragment thereof, of the present invention comprises CDRL1, CDRL2 and CDRL3, which comprise the amino acid sequences of SEQ ID NOS: 11, 12 and 13, respectively. In a preferred embodiment, said humanized antibody or an antigen-binding fragment thereof, of the present invention comprises CDRH1, CDRH2, CDRH3, CDRL1, CDRL2 and CDRL3, which comprise the amino acid sequences of SEQ ID NOS:4, 5, 6, 11, 12 and 13, respectively. In another alternative, said humanized antibody or an antigen-binding fragment thereof, of the present invention comprises a FRH derived from a variable region of a human H-chain encoded by GenBank Accession No. X65891 (SEQ ID NO:18), or a FRL derived from a variable region of a human κ-L-chain encoded by GenBank Accession No. X72441 (SEQ ID NO:23). In a preferred embodiment, the FRH of the humanized antibody of the present invention comprises at least one amino acid sequence selected from the group consisting of the amino acid sequences of SEQ ID NOS:19, 20, 21 and 22 (FRH1, FRH2, FRH3 and FRH4, respectively, encoded by the corresponding portions of X65891). In another preferred embodiment, the FRL of the humanized antibody of the present invention comprises at least one amino acid sequence selected from the group consisting of the amino acid sequences of SEQ ID NOS:24, 25, 26 and 27 (FRL1, FRL2, FRL3 and FRL4, respectively, encoded by the corresponding portions of X72441). In a most preferred embodiment, the humanized antibody or an antigen-binding fragment

thereof, of the present invention comprises: (i) a H-chain variable region (VH region) comprising the amino acid sequence of SEQ ID NO:29; or (ii) a L-chain variable region (VL region) comprising the amino acid sequence of SEQ ID NO:31; or (iii) both (i) and (ii) above.

5   In another preferred specific embodiment, the humanized antibody or an antigen-binding fragment thereof, of the present invention comprises: (i) at least one FRH derived from a human FRH, and at least one CDRH comprising an amino acid sequence selected from the group consisting of the amino acid sequences of SEQ ID NOS:32, 33 and 34; or (ii) at least one FRL derived from a human FRL, and 10   at least one CDRL comprising an amino acid sequence selected from the group consisting of the amino acid sequences of SEQ ID NOS:37, 38 and 39; or (iii) both (i) and (ii) above.   Said humanized antibody or an antigen-binding fragment thereof, of the present invention may comprise CDRH1, CDRH2 and CDRH3, which comprise the amino acid sequences of SEQ ID NOS:32, 33 and 34, respectively.   In 15   the alternative, said humanized antibody or an antigen-binding fragment thereof, of the present invention comprises CDRL1, CDRL2 and CDRL3, which comprise the amino acid sequences of SEQ ID NOS:37, 38 and 39, respectively.   In a preferred embodiment, said humanized antibody or an antigen-binding fragment thereof, of the present invention comprises CDRH1, CDRH2, CDRH3, CDRL1, CDRL2 and 20   CDRL3, which comprise the amino acid sequences of SEQ ID NOS:32, 33, 34, 37, 38 and 39, respectively.

            In another preferred specific embodiment, the humanized antibody or an antigen-binding fragment thereof, of the present invention comprises: (i) at least one FRH derived from a human FRH, and at least one CDRH comprising an amino 25   acid sequence selected from the group consisting of the amino acid sequences of SEQ ID NOS:42, 43 and 44; or (ii) at least one FRL derived from a human FRL, and at least one CDRL comprising an amino acid sequence selected from the group consisting of the amino acid sequences of SEQ ID NOS:47, 48 and 49; or (iii) both (i) and (ii) above.   Said humanized antibody or an antigen-binding fragment thereof, 30   of the present invention may comprise CDRH1, CDRH2 and CDRH3, which comprise the amino acid sequences of SEQ ID NOS:42, 43 and 44, respectively.   In the alternative, said humanized antibody or an antigen-binding fragment thereof, of the present invention comprises CDRL1, CDRL2 and CDRL3, which comprise the

amino acid sequences of SEQ ID NOS:47, 48 and 49, respectively.   In a preferred

embodiment, said humanized antibody or an antigen-binding fragment thereof, of the

present invention comprises CDRH1, CDRH2, CDRH3, CDRL1, CDRL2 and

CDRL3, which comprise the amino acid sequences of SEQ ID NOS: 42, 43, 44, 47,

5   48 and 49, respectively.

         In another preferred specific embodiment, the humanized antibody or an

antigen-binding fragment thereof, of the present invention comprises: (i) at least

one FRH derived from a human FRH, and at least one CDRH comprising an amino

acid sequence selected from the group consisting of the amino acid sequences of

10   SEQ ID NOS:52, 53 and 54; or (ii) at least one FRL derived from a human FRL, and

at least one CDRL comprising an amino acid sequence selected from the group

consisting of the amino acid sequences of SEQ ID NOS:57, 58 and 59; or (iii) both

(i) and (ii) above.   Said humanized antibody or an antigen-binding fragment thereof,

of the present invention may comprise CDRH1, CDRH2 and CDRH3, which

15   comprise the amino acid sequences of SEQ ID NOS:52, 53 and 54, respectively.   In

the alternative, said humanized antibody or an antigen-binding fragment thereof, of

the present invention comprises CDRL1, CDRL2 and CDRL3, which comprise the

amino acid sequences of SEQ ID NOS:57, 58 and 59, respectively.   In a preferred

embodiment, said humanized antibody or an antigen-binding fragment thereof, of the

20   present invention comprises CDRH1, CDRH2, CDRH3, CDRL1, CDRL2 and

CDRL3, which comprise the amino acid sequences of SEQ ID NOS:52, 53, 54, 57,

58 and 59, respectively.

         In another preferred specific embodiment, the humanized antibody or an

antigen-binding fragment thereof, of the present invention comprises: (i) at least

25   one FRH derived from a human FRH, and at least one CDRH comprising an amino

acid sequence selected from the group consisting of the amino acid sequences of

SEQ ID NOS:62, 63 and 64; or (ii) at least one FRL derived from a human FRL, and

at least one CDRL comprising an amino acid sequence selected from the group

consisting of the amino acid sequences of SEQ ID NOS:67, 68 and 69; or (iii) both

30   (i) and (ii) above.   Said humanized antibody or an antigen-binding fragment thereof,

of the present invention may comprise CDRH1, CDRH2 and CDRH3, which

comprise the amino acid sequences of SEQ ID NOS:62, 63 and 64, respectively.   In

the alternative, said humanized antibody or an antigen-binding fragment thereof, of

the present invention comprises CDRL1, CDRL2 and CDRL3, which comprise the
amino acid sequences of SEQ ID NOS:67, 68 and 69, respectively.   In a preferred
embodiment, said humanized antibody or an antigen-binding fragment thereof, of the
present invention comprises CDRH1, CDRH2, CDRH3, CDRL1, CDRL2 and
5   CDRL3, which comprise the amino acid sequences of SEQ ID NOS:62, 63, 64, 67,
68 and 69, respectively.

The present invention further provides an isolated nucleic acid molecule
comprising a nucleotide sequence encoding the humanized antibody or an
antigen-binding fragment thereof of the present invention which immunospecifically
10   recognizes human α9 integrin.   Specifically, the present invention provides an
isolated nucleic acid molecule comprising a nucleotide sequence encoding a
humanized H-chain comprising at least one amino acid sequence selected from the
group consisting of SEQ ID NOS:4, 5, 6, 32, 33, 34, 42, 43, 44, 52, 53, 54, 62, 63
and 64, or a humanized L-chain comprising at least one amino acid sequence
15   selected from the group consisting of SEQ ID NOS:11, 12, 13, 37, 38, 39, 47, 48, 49,
57, 58, 59, 67, 68 and 69, or both said humanized H-chain and said humanized
L-chain.   In a preferred specific embodiment, such an isolated nucleic acid
molecule comprises the nucleotide sequence of SEQ ID NO:28, which encodes a VH
region, or a nucleotide sequence encoding the amino acid sequence of SEQ ID
20   NO:29.   In another preferred specific embodiment, such an isolated nucleic acid
molecule comprises the nucleotide sequence of SEQ ID NO:30, which encodes a VL
region, or a nucleotide sequence encoding the amino acid sequence of SEQ ID
NO:31.   In yet another preferred specific embodiment, the isolated nucleic acid
molecule of the present invention comprises the nucleotide sequences of both SEQ
25   ID NO:28 and 30.   In yet another preferred specific embodiment, the isolated
nucleic acid molecule of the present invention further comprises a nucleotide
sequence encoding a signal peptide of donor origin, such as the amino acid
sequences of SEQ ID NOS:10 and 17, respectively, or of heterologous origin.

The present invention further provides a vector, *e.g.*, an expression vector,
30   comprising a nucleotide sequence encoding a H-chain or a L-chain, or both, of the
humanized antibody or an antigen-binding fragment thereof of the present invention
that immunospecifically recognizes human α9 integrin.   In such a vector, the
nucleotide sequence of the present invention may be operably linked to one or more

regulatory elements.   The nucleotide sequence of the present invention may include a nucleotide sequence encoding a signal peptide native to a non-human donor antibody from which a CDR is derived, or a signal peptide of heterologous origin.

Furthermore, the present invention provides a host cell comprising the nucleic acid molecule of the present invention, including a vector comprising the nucleic acid molecule of the present invention.   In one embodiment, the present invention provides an isolated host cell comprising a first nucleic acid molecule encoding a humanized H-chain of the present invention and a second nucleic acid molecule encoding a humanized L-chain of the present invention, said first and second nucleic acid molecules are each operably linked to a regulatory element in such a way that the biologically functional humanized antibody or antigen-binding fragment thereof of the present invention is expressed.

Accordingly, the present invention further provides a method for preparing the humanized antibody of the present invention, comprising culturing the host cell of the invention under conditions so that the humanized antibody is expressed; and collecting the produced humanized antibody.

The present invention further provides a composition comprising at least one of the humanized antibodies of the present invention.   In addition, the present invention provides a pharmaceutical composition for preventing or treating a disorder or disease that is associated with $\alpha 9$ integrin, comprising at least one of the humanized antibodies of the present invention, and a pharmaceutically acceptable carrier.   Either of said compositions can further comprise another active compound that can additively or synergistically ameliorate the disorder or disease.   Such an active compound includes, but not by way of limitation, anti-inflammatory compounds, chemotherapeutic compounds, and the like, as well as an antibody or an antigen-binding fragment thereof, such as an antibody that can immunospecifically bind human $\alpha 4$ integrin.

In another aspect, the present invention provides a method for preventing or treating a disorder or disease that is associated with or involves $\alpha 9$ integrin, said method comprising administering a prophylactically or therapeutically effective amount of at least one of the humanized antibodies of the present invention to a subject in need thereof.   For such uses, the humanized antibody of the present

9

invention may be conjugated to a therapeutic moiety that enhances the biological effect of the humanized antibody.   Examples of such a therapeutic moiety include another antibody, such as anti-α4 antibody (*e.g.*, to form a bispecific antibody), cytotoxins that are cytostatic or cytocidal, radioactive elements, and/or other therapeutic agents, including anti-inflammatory agents, antibiotics, and the like.

In yet another aspect, the present invention provides a method for diagnosing a disorder or disease, in a subject, that is associated with or involves α9 integrin, said method comprising administering a diagnostically effective amount of the humanized antibody of the present invention to a subject to be examined.   For such diagnostic uses, the humanized antibody of the present invention may be labeled with detectable markers, such as radioactive elements.

3.1. Definitions

As used herein, the term "antibody" refers to an antibody molecule capable of immunospecifically binding to a desired antigen, such as the α9 integrin, and encompasses an antibody molecule as a whole or a fragment thereof, including an antigen-binding fragment.

The term "immunospecifically recognize" used herein refers to an ability of an antibody or an antigen-binding fragment thereof to bind specifically to a target polypeptide or protein, in particular, human α9 integrin.   Such an antibody does not non-specifically bind to other polypeptides or proteins.   However, an antibody or an antigen-binding fragment thereof that immunospecifically binds to the target polypeptide or protein (*e.g.*, human α9 integrin) may cross-react with other antigens. For example, the humanized antibody or an antigen-binding fragment of the present invention that immunospecifically recognizes human α9 integrin may cross-react with, for example, murine α9 integrin.   Preferably, an antibody or an antigen-binding fragment thereof that immunospecifically binds to human α9 integrin does not cross-react with other antigens.

The term "an antigen-binding fragment" used herein refers to any fragment of an antibody that retains an ability to immunospecifically bind to a target polypeptide or protein, in particular, human α9 integrin and/or mouse α9 integrin, and includes single chain antibodies, Fab fragments, F(ab')₂ fragments, disulfide-linked Fvs, and fragments containing either a variable region of a light chain (VL) and/or a variable

region of a heavy chain (VH) or even a complementary determining region (CDR) that specifically binds to a target polypeptide or protein. Thus, such antigen-binding fragments of humanized antibody may or may not include partial or full-length human constant regions. Various methods for obtaining the antibody fragments described above are well known in the art.

The term "derived from a human source" or "derived from a non-human source" used herein refers to an antibody portion whose amino acid sequence is derived from a corresponding portion of a human antibody or of a non-human antibody.

The term "an acceptor sequence" used herein refers to a nucleotide sequence or an amino acid sequence of framework regions from a human antibody VH or VL region that serves as an acceptor for CDRs from a donor antibody, which is usually a non-human antibody.

The present invention also provides a humanized antibody or an antigen-binding fragment thereof that immunospecifically recognizes human α9 integrin, comprising:

a H-chain comprising the amino acid sequence of SEQ ID NO:29, and at least one CDRH derived from at least one of CDRHs of a non-human antibody that immunospecifically recognizes human α9 integrin; and

a L-chain comprising the amino acid sequence of SEQ ID NO:31, and at least one CDRL derived from at least one of CDRLs of a non-human antibody that immunospecifically recognizes human α9 integrin.

The present invention also provides an isolated nucleic acid molecule comprising a nucleotide sequence encoding the amino acid sequence of SEQ ID NO:29.

The present invention also provides an isolated nucleic acid molecule comprising a nucleotide sequence encoding the amino acid sequence of SEQ ID NO:31.

4. BRIEF DESCRIPTION OF THE FIGURES

Fig. 1 shows the nucleotide sequence (SEQ ID NO:7) of mouse 24I11 VH cDNA along with the deduced amino acid sequence (SEQ ID NO:8). Amino acid

11

residues are shown in single letter code. The signal peptide sequence (SEQ ID NO:10) is in italic. The N-terminal amino acid residue (E) of the mature VH is double-underlined. CDR sequences according to the definition of Kabat *et al.* (Sequences of Proteins of Immunological Interests, Fifth edition, NIH Publication No. 91-3242, U.S.

5   Department of Health and Human Services, 1991) are underlined.

Fig. 2 shows the nucleotide sequence (SEQ ID NO:14) of mouse 24I11 VL cDNA along with the deduced amino acid sequence (SEQ ID NO:15). Amino acid residues are shown in single letter code. The signal peptide sequence (SEQ ID NO:17) is in italic. The N-terminal amino acid residue (D) of the mature VL is double-

10   underlined. CDR sequences according to the definition of Kabat et al. (1991) are underlined.

Fig. 3 shows the nucleotide sequence (SEQ ID NO:72) of the designed 24I11 VH gene flanked by SpeI and HindIII sites (underlined), along with the deduced amino acid sequence (SEQ ID NO:8). Amino acid residues are shown in single letter code.

15   The signal peptide sequence (SEQ ID NO:10) is in italic. The

N-terminal amino acid residue (E) of the mature VH is double-underlined.   CDR
sequences according to the definition of Kabat et al. (1991) are underlined.   The
intron sequence is in italic.

Fig. 4 shows the nucleotide sequence (SEQ ID NO:73) of the designed 24I11

5   VL gene flanked by NheI and EcoRI sites (underlined), along with the deduced
amino acid sequence (SEQ ID NO:15).   Amino acid residues are shown in single
letter code.   The signal peptide sequence (SEQ ID NO:17) is in italic.   The
N-terminal amino acid residue (D) of the mature VL is double-underlined.   CDR
sequences according to the definition of Kabat et al. (1991) are underlined.   The

10   intron sequence is in italic.

Fig. 5 shows the schematic structure of pCh24I11 and pHu24I11 (collectively
Expression Vector).   Proceeding clockwise from the SalI site at the top, the plasmid
contains the heavy chain transcription unit starting with the human cytomegalovirus
(CMV) major immediate early promoter and enhancer (CMV promoter) to initiate

15   transcription of the antibody heavy chain gene.   The CMV promoter is followed by
the VH exon, a genomic sequence containing the human gamma-1 heavy chain
constant region including the CH1, hinge, CH2 and CH3 exons with the intervening
introns, and a polyadenylation site of the gamma-1 gene for mRNA processing
following CH3.   After the heavy chain gene sequence, the light chain transcription

20   unit begins with the CMV promoter, followed by the VL exon and a genomic
sequence containing the human kappa chain constant region exon (CL) with part of
the intron preceding it, and a poly A signal of the kappa gene.   The light chain gene
is then followed by the SV40 early promoter (SV40 promoter), the E. coli xanthine
guanine phosphoribosyl transferase gene (gpt), and a segment containing the SV40

25   polyadenylation site (SV40 poly(A) site).   Finally, the plasmid contains a part of the
plasmid pUC19, comprising the bacterial origin of replication (pUC ori) and
beta-lactamase gene (beta lactamase).

Fig. 6 shows the alignment of the amino acid sequences of 24I11 VH (SEQ
ID NO:9), humanized 24I11 (Hu24I11) VH (SEQ ID NO:29) and FRH1 (SEQ ID

30   NO:19), FRH2 (SEQ ID NO:20), FRH3 (SEQ ID NO:21) and FRH4 (SEQ ID
NO:22) of human acceptor sequences, derived from the amino acid sequence
encoded by the nucleotide sequence of GenBank Accession No. X65891.   Amino
acid residues are shown in single letter code.   Numbers above the sequences

indicate the positions according to Kabat *et al.* (1991). CDR sequences defined by Kabat *et al.* (1991) are underlined. Double-underlined residues were predicted to contact with the CDRs and the mouse residues were retained at these locations in the humanized form. CDR residues in X65891 are omitted in the figure.

5   **Fig. 7** shows the alignment of the amino acid sequences of 24I11 VL (SEQ ID NO:16), humanized 24I11 (Hu24I11) VL (SEQ ID NO:31) and FRL1 (SEQ ID NO:24), FRL2 (SEQ ID NO:25), FRL3 (SEQ ID NO:26) and FRL4 (SEQ ID NO:27) of human acceptor sequences, derived from the amino acid sequence encoded by the nucleotide sequence of GenBank Accession No. X72441. Amino acid residues are
10   shown in single letter code. Numbers above the sequences indicate the positions according to Kabat et al. (1991). CDR sequences defined by Kabat et al. (1991) are underlined. Double-underlined residues were predicted to contact with the CDRs and the mouse residues were retained at these locations in the humanized form. CDR residues in X72441 are omitted in the figure.

15   **Fig. 8** shows the oligonucleotides used for construction of the Hu24I11 VH gene.

           Fig. 9 shows the oligonucleotides used for construction of the Hu24I11 VL gene.

           Fig. 10 shows the oligonucleotides used for construction of the Hu24I11 VH
20   gene flanked by SpeI and HindIII sites (SEQ ID NO:74 with 5'-GGG tail at 5'-terminal and CCC-3' tail at 3'-terminal). An arrow denotes the position and orientation (5' to 3') of each oligonucleotide. Amino acid residues of the signal peptide (SEQ ID NO:10) and the VH region (SEQ ID NO:29) are shown in single letter code.

25   **Fig. 11** shows oligonucleotides used for construction of the Hu24I11 VL gene flanked by NheI and EcoRI sites (SEQ ID NO:75 with 5'-GGG tail at 5'-terminal and CCC-3' tail at 3'-terminal). An arrow denotes the position and orientation (5' to 3') of each oligonucleotide. Amino acid residues of the signal peptide (SEQ ID NO:17) and the VL region (SEQ ID NO:31) are shown in single letter code.

30   **Fig. 12** shows the nucleotide sequence (SEQ ID NO:74) of the Hu24I11 VH gene flanked by SpeI and HindIII sites (underlined), along with the deduced amino acid sequence of the signal peptide (SEQ ID NO:10; shown in italic) and the VH

region (SEQ ID NO:29).   Amino acid residues are shown in single letter code.
The N-terminal amino acid residue (Q) of the mature VH is double-underlined.
CDR sequences according to the definition of Kabat et al. (1991) are underlined.
The intron sequence is in italic.

5   **Fig. 13** shows the nucleotide sequence (SEQ ID NO:75) of the Hu24I11 VL
gene flanked by NheI and EcoRI sites (underlined), along with the deduced amino
acid sequence of the signal peptide (SEQ ID NO:17; shown in italic) and the VL
region (SEQ ID NO:31).   Amino acid residues are shown in single letter code.
The N-terminal amino acid residue (D) of the mature VL is double-underlined.
10   CDR sequences according to the definition of Kabat et al. (1991) are underlined.
The intron sequence is in italic.

         Fig. 14 shows the comparison of the affinity of chimeric and humanized
24I11 antibodies to human α9 integrin.   The binding of chimeric and humanized
24I11 at 1 and 0.5 μg/ml to CHO/α9 cells was examined by cell ELISA.
15   Experiments were carried out in triplicate.   The mean absorbance value with SEM
is shown in the figure.

         Fig. 15 shows the result of the FACS analysis of the binding of mouse,
chimeric and humanized 24I11 antibodies to human α9 integrin.   Each antibody
was tested at 1, 0.33, 0.11, 0.037 and 0.012 μg/ml for binding to CHO/huα9 cells.
20   Geometric mean channel fluorescence values (MCF; Y-axis) are plotted at each
antibody concentration tested (X-axis) in the figure.

         Fig. 16 shows the result of cell adhesion inhibitory activity of anti-human α9
integrin antibodies, between Human α9/CHO-K1 cells and hOPN(RAA)N-half,
Tenascin-C, VCAM-1, or human fibronectin.

25   **Fig. 17** shows the result of cell adhesion inhibitory effects of anti-human α9
integrin antibodies on human melanoma cells in the presence of anti-human α4
integrin.

         Fig. 18 shows therapeutic effects on hepatitis by the anti-α4 integrin
antibodies and the anti-α9-integrin antibodies.   In the Figure, NHG indicates
30   normal hamster antibody and NRG indicates normal rat antibody.

         Fig. 19 shows that growth of the B16-BL6 cells was inhibited by the anti-α9

integrin antibodies.

Fig. 20 shows the results of FACS analysis using anti-human α9 integrin antibodies for Human α9/CHO-K1 cells (Fig. 20a), Human α4/CHO-K1 (Fig. 20b) and human neutrophils (Fig. 20c).

5   Fig. 21 shows the cell growth inhibition of the B16-BL6 cells by the anti-α9 integrin antibodies using immobilized VCAM-1 as an ECM.

Fig. 22 shows the therapeutic effect of anti-α9 integrin in a mouse rheumatoid arthritis model.

10   **5. DETAILED DESCRIPTION OF THE INVENTION**

5.1. Preparation of Antibodies Against Human α9 Integrin

Antibodies that immunospecifically recognize human α9 integrin or any epitope thereof may be generated by any suitable method known in the art.

The α9 integrin used as an antigen in the present invention may be (1) 15   proteins derived from all cells from human that express α9 integrin, or all tissues where these cells are present, (2) recombinant proteins in which the α9 integrin-encoding gene DNA, preferably cDNA, is transfected into bacteria, yeast, cell lines including animal cells, etc. and expressed, or (3) synthetic proteins.

The α9 integrin includes polypeptides comprising substantially the same 20   amino acid sequences as the amino acid sequences of human α9 integrins (SEQ ID NO:76, wherein 1-29 residues are the signal peptide).

Herein, the term "polypeptides comprising substantially the same amino acid sequence" means variant polypeptides comprising an amino acid sequence, in which multiple amino acids, preferably 1 to 10 amino acids and more preferably 1 to 25   several (e.g., 1 to 5) amino acids are substituted, deleted and/or modified, as long as these variant polypeptides have biological properties substantially equivalent to the naturally occurring human α9 integrin; and variant polypeptides comprising an amino acid sequence, wherein multiple amino acids, preferably 1 to 10 amino acids and more preferably 1 to several (e.g., 1 to 5) amino acids are added to the amino 30   acid sequence of naturally occurring human α9 integrin.   Furthermore, the variant

polypeptides may be those having a plurality of these substitutions, deletions, modifications and additions of amino acids.

The human α9 integrin as an antigen in the present invention can be produced by methods well known in the art, such as chemical synthesis method, cell
5   culture method, etc., or their modifications, in addition to the gene recombinant techniques.

Examples of the methods for producing variant polypeptides include a synthetic oligonucleotide site-directed mutagenesis (gapped duplex method), a point mutagenesis method which involves introducing a point mutation at random by
10   treatment with nitrite or sulfite, a method which involves preparing a deletion mutant with Bal31 enzyme, or other enzymes, a cassette mutagenesis, a linker scanning method, a miss incorporation method, a mismatch primer method, a DNA segment synthesis method, and the like.

The human α9 integrin to be used as an antigen in the present invention also
15   includes a "part" of said α9 integrin.   As used herein, the "part" refers to a part comprising a region required for binding to a ligand of the α9 integrin, for example, OPN, VCAM-1, tenascin-C, etc.; specifically, a part comprising the 14th-980th amino acid residues, and a part comprising the 11th-981st amino acid residues, of the mature human α9 integrin (the 30th-1035th amino acid residues of SEQ ID NO:76).
20   The "part" of said α9 integrin can be produced by gene recombination or chemical synthesis according to methods known in the art described below, or modifications thereof, or can be produced by appropriately digesting the human α9 integrin isolated by the cell culture method with a proteolytic enzyme or the like.

As an antigen, a cell per se that overexpresses the α9 integrin on the cell
25   membrane, or a membrane fraction thereof, can be also used.   Cells overexpressing human α9 integrin can be prepared by recombinant DNA technologies well known in the art.

Using appropriate antigens prepared as described above, antibodies specific for human α9 integrin or any epitope thereof may be prepared by various methods
30   well known in the art.   Polyclonal antibodies to human α9 integrin can be produced by various procedures well known in the art.   For example, an antigen of interest can be administered to various host animals including, but not limited to, rabbits,

mice, rats, etc., to induce the production of antisera containing polyclonal antibodies
specific for the antigen.   Various adjuvants may be used to increase the
immunological response, depending on the host species, and include but are not
limited to, Freund's (complete and incomplete) adjuvant, mineral gels such as
5   aluminum hydroxide, surface active substances such as lysolecithin, pluronic
polyols, polyanions, peptides, oil emulsions, keyhole limpet hemocyanins,
dinitrophenol, and potentially useful adjuvants for humans such as BCG (Bacille
Calmette-Guerin) and Corynebacterium parvum.   Such adjuvants are also well
known in the art.

10   Monoclonal antibodies can be prepared using a wide variety of techniques
known in the art including the use of hybridoma, recombinant, and phage display
technologies, or a combination thereof.   For example, monoclonal antibodies can be
produced using hybridoma techniques including those known in the art and taught,
for example, in Harlow et al., Antibodies: A Laboratory Manual, (Cold Spring
15   Harbor Laboratory Press, 2nd ed. 1988); Hammerling, et al., in: Monoclonal
Antibodies and T-Cell Hybridomas, pp. 563-681 (Elsevier, N.Y., 1981) (both of
which are incorporated by reference in their entireties).   The term "monoclonal
antibody" as used herein is not limited to antibodies produced through hybridoma
technology.   The term "monoclonal antibody" refers to an antibody that is derived
20   from a single clone, including any eukaryotic, prokaryotic, or phage clone, and not
the method by which it is produced.

        Methods for producing and screening for specific antibodies using hybridoma
technology are routine and well known in the art.   In a non-limiting example, mice
can be immunized with an antigen of interest or a cell expressing such an antigen.
25   Once an immune response is detected, e.g., antibodies specific for the antigen are
detected in the mouse serum, the mouse spleen is harvested and splenocytes isolated.
The splenocytes are then fused by well known techniques to any suitable myeloma
cells (e.g., P3U1, P3X63-Ag8, P3X63-Ag8-U1, P3NS1-Ag4, SP2/0-Ag14,
P3X63-Ag8-653, etc.).   Hybridomas are selected and cloned by limiting dilution.
30   The hybridoma clones are then assayed by methods known in the art for cells that
secrete antibodies capable of binding the antigen.   Ascites fluid, which generally
contains high levels of antibodies, can be generated by inoculating mice
intraperitoneally with positive hybridoma clones.

17

Antibody fragments what recognize specific epitopes may be generated by known techniques. For example, Fab and F(ab')$_2$ fragments may be produced by proteolytic cleavage of immunoglobulin molecules, using enzymes such as papain (to produce Fab fragments) or pepsin (to produce F(ab')$_2$ fragments). F(ab')$_2$

5   fragments contain the complete light chain, and the variable region, the CH1 region and the hinge region of the heavy chain.

The antibodies of the invention or an antigen-binding fragment thereof can be also produced by any method known in the art for the synthesis of antibodies, in particular, by chemical synthesis or preferably, by recombinant expression

10   techniques.

The nucleotide sequence encoding an antibody may be obtained from any information available to those skilled in the art (i.e., from Genbank, the literature, or by routine cloning and sequence analysis). If a clone containing a nucleic acid encoding a particular antibody or an epitope-binding fragment thereof is not

15   available, but the sequence of the antibody molecule or epitope-binding fragment thereof is known, a nucleic acid encoding the immunoglobulin may be chemically synthesized or obtained from a suitable source (e.g., an antibody cDNA library, or a cDNA library generated from, or nucleic acid, preferably poly A+ RNA, isolated from any tissue or cells expressing the antibody, such as hybridoma cells selected to

20   express an antibody) by PCR amplification using synthetic primers hybridizable to the and 5' ends of the sequence or by cloning using an oligonucleotide probe specific for the particular gene sequence to identify, e.g., a cDNA clone from a cDNA library that encodes the antibody. Amplified nucleic acids generated by PCR may then be cloned into replicable cloning vectors using any method well known in

25   the art.

5.2. Preparation of Recombinant Antibodies

Once the nucleotide sequence of the antibody is determined, the nucleotide sequence of the antibody may be manipulated using methods well known in the art for the manipulation of nucleotide sequences, e.g., recombinant DNA techniques, site

30   directed mutagenesis, PCR, etc. (see, for example, the techniques described in Sambrook et al., supra; and Ausubel et al., eds., 1998, Current Protocols in Molecular Biology, John Wiley & Sons, NY, which are both incorporated by reference herein in

their entireties), to generate antibodies having a different amino acid sequence by, for example, introducing amino acid substitutions, deletions, and/or insertions into the epitope-binding domain regions of the antibodies or any portion of antibodies which may enhance or reduce biological activities of the antibodies.

5   Recombinant expression of an antibody requires construction of an expression vector containing a nucleotide sequence that encodes the antibody. Once a nucleotide sequence encoding an antibody molecule or a heavy or light chain of an antibody, or portion thereof has been obtained, the vector for the production of the antibody molecule may be produced by recombinant DNA technology using

10   techniques well known in the art as discussed in the previous sections.   Methods which are well known to those skilled in the art can be used to construct expression vectors containing antibody coding sequences and appropriate transcriptional and translational control signals.   These methods include, for example, in vitro recombinant DNA techniques, synthetic techniques, and in vivo genetic

15   recombination.   The nucleotide sequence encoding the heavy-chain variable region, light-chain variable region, both the heavy-chain and light-chain variable regions, an epitope-binding fragment of the heavy- and/or light-chain variable region, or one or more complementarity determining regions (CDRs) of an antibody may be cloned into such a vector for expression.   Such a sequence may be fused with a

20   polynucleotide encoding a signal peptide native to the original antibody or a heterologous signal peptide.   Thus-prepared expression vector can be then introduced into appropriate host cells for the expression of the antibody. Accordingly, the invention includes host cells containing a polynucleotide encoding a humanized antibody or an antigen-binding fragment thereof that immunospecifically

25   recognizes human $\alpha 9$ integrin.

          The host cell may be co-transfected with two expression vectors of the invention, the first vector encoding a heavy chain derived polypeptide and the second vector encoding a light chain derived polypeptide.   The two vectors may contain identical selectable markers which enable equal expression of heavy and light chain

30   polypeptides or different selectable markers to ensure maintenance of both plasmids. Alternatively, a single vector may be used which encodes, and is capable of expressing, both heavy and light chain polypeptides.   The coding sequences for the heavy and light chains may comprise cDNA or genomic DNA.

In another embodiment, antibodies can also be generated using various phage display methods known in the art.   In phage display methods, functional antibody domains are displayed on the surface of phage particles which carry the polynucleotide sequences encoding them.   In a particular embodiment, such phage

5   can be utilized to display antigen binding domains, such as Fab and Fv or disulfide-bond stabilized Fv, expressed from a repertoire or combinatorial antibody library (e.g., human or murine).   Phage expressing an antigen binding domain that binds the antigen of interest can be selected or identified with antigen, e.g., using labeled antigen or antigen bound or captured to a solid surface or bead.   Phage used

10   in these methods are typically filamentous phage, including fd and M13.   The antigen binding domains are expressed as a recombinantly fused protein to either the phage gene III or gene VIII protein.   Examples of phage display methods that can be used to make the immunoglobulins, or fragments thereof, of the present invention include those disclosed in Brinkman et al., J. Immunol. Methods, 182:41-50, 1995;

15   Ames et al., J. Immunol. Methods, 184:177-186, 1995; Kettleborough et al., Eur. J. Immunol., 24:952-958, 1994; Persic et al., Gene, 187:9-18, 1997; Burton et al., Advances in Immunology, 57:191-280, 1994; PCT application No. PCT/GB91/01134; PCT publications WO 90/02809; WO 91/10737; WO 92/01047; WO 92/18619; WO 93/11236; WO 95/15982; WO 95/20401; and U.S. Patent Nos.

20   5,698,426; 5,223,409; 5,403,484; 5,580,717; 5,427,908; 5,750,753; 5,821,047; 5,571,698; 5,427,908; 5,516,637; 5,780,225; 5,658,727; 5,733,743 and 5,969,108; each of which is incorporated herein by reference in its entirety.

As described in the above references, after phage selection, the antibody coding regions from the phage can be isolated and used to generate whole antibodies,

25   including human antibodies, or any other desired fragments, and expressed in any desired host, including mammalian cells, insect cells, plant cells, yeast, and bacteria, e.g., as described in detail below.   For example, techniques to recombinantly produce Fab, Fab' and F(ab)2 fragments can also be employed using methods known in the art such as those disclosed in PCT publication WO 92/22324; Mullinax et al.,

30   BioTechniques, 12(6):864-869,   1992; and Sawai et al., AJRI, 34:26-34, 1995; and Better et al., Science, 240:1041-1043, 1988 (each of which is incorporated by reference in its entirety).   Examples of techniques which can be used to produce single-chain Fvs and antibodies include those described in U.S. Patent Nos.

4,946,778 and 5,258,498; Huston et al., Methods in Enzymology, 203:46-88, 1991;
Shu et al., PNAS, 90:7995-7999, 1993; and Skerra et al., Science, 240:1038-1040,
1988.

5   Once an antibody molecule of the invention has been produced by any
methods described above, it may then be purified by any method known in the art for
purification of an immunoglobulin molecule, for example, by chromatography (e.g.,
ion exchange, affinity, particularly by affinity for the specific antigen after Protein A
or Protein G purification, and sizing column chromatography), centrifugation,
differential solubility, or by any other standard techniques for the purification of
10   proteins.   Further, the antibodies of the present invention or fragments thereof may
be fused to heterologous polypeptide sequences described herein or otherwise known
in the art to facilitate purification.

For some uses, including *in vivo* use of antibodies in humans and *in vitro*
detection assays, it may be preferable to use chimeric, humanized, or human
15   antibodies.   Chimeric antibodies and humanized antibodies are discussed in details
in Section 5.3, *infra*.

Antibodies fused or conjugated to other compounds or heterologous
polypeptides may be used in *in vitro* immunoassays, in purification methods (e.g.,
affinity chromatography), as well as *in vivo* therapeutic or diagnostic uses.   See e.g.,
20   PCT publication Number WO 93/21232; EP 439,095; Naramura et al., Immunol.
Lett., 39:91-99,   1994; U.S. Patent 5,474,981; Gillies et al., PNAS, 89:1428-1432,
1992; and Fell et al., J. Immunol., 146:2446-2452, 1991, which are incorporated
herein by reference in their entireties.   For example, antibodies can be labeled in
various ways using a known method or commercially available kit (e.g., biotin
25   labeling, FITC labeling, APC labeling).   As another example, antibodies may be
conjugated to a therapeutic moiety that enhances the biological effect of the
antibodies *in vivo*.   Examples of such a therapeutic moiety include another antibody,
cytotoxins that are cytostatic or cytocidal, radioactive element, and/or other
therapeutic agents, including anti-inflammatory agents, antibiotics, and the like.   In
30   the present invention, the humanized anti-human α9 integrin may be conjugated to
another antibody, such as anti-α4 antibody (*e.g.*, to form a bispecific antibody).   As
another example, the humanized antibody of the present invention may be labeled
with detectable markers, such as radioactive elements, for *in vivo* diagnostic uses.

5.3. Chimeric and Humanized Antibodies

A chimeric antibody is a molecule in which different portions of the antibody are derived from different animal species, such as antibodies having a variable region derived from a murine monoclonal antibody and a constant region derived from a human immunoglobulin. Methods for producing chimeric antibodies are known in the art. See e.g., Morrison, Science, 229:1202, 1985; Oi et al., BioTechniques, 4:214 1986; Gillies et al., J. Immunol. Methods, 125:191-202, 1989; U.S. Patent Nos. 5,807,715; 4,816,567; and 4,816,397, which are incorporated herein by reference in their entireties.

A humanized antibody is a molecule that binds a desired antigen and comprises a variable region containing one or more complementarity determining regions (CDRs) derived from a non-human species and one or more framework regions derived from a human immunoglobulin molecule. The typical methods for humanizing non-human antibodies have been described in various references, such as those: by Queen et al., 1989, *Proc. Natl. Acad. Sci. USA* 86:10029-10033 and U.S. Patent Nos. 5,585,089 and 5,693,762; by Riechmann et al., *Nature*, 332:323, 1988; and by Tsurushita *et al.*, *Methods* 36:69-83, 2005, all of which are incorporated herein by reference in their entireties). For example, the reference by Tsurushita *et al.* (2005, *supra*; hereafter "*Tsurushita*") provides a practical and instructive protocol for the humanization of mouse monoclonal antibodies based on the antibody-humanization method originally developed by Queen *et al.* (1989, *supra*). The general protocol disclosed in *Tsurushita* is briefly summarized below.

5.3.1. General protocol for preparing humanized antibodies

Cloning and sequencing of mouse V genes

Various methods are available for cloning cDNAs encoding the VH and VL regions of a target mouse monoclonal antibody. For example, 5' RACE (rapid amplification of cDNA ends) method using SMART RACE cDNA Amplification Kit (BD Biosciences, CA) or the GeneRacer Kit (Invitrogen, CA) has been commonly used. A gene-specific primer for 5' RACE can be prepared based on the isotypes of the H-chain and the L-chain of the target monoclonal antibody so that it can bind immediately downstream of the variable region for each of the H-chain and L-chain. Thus, 5' RACE primer may be designed to be specific for each subtype in mouse,

such as γ1, γ2a, γ2b or γ3.   Alternatively, a common primer for all subtypes may be designed based on the consensus or highly homologous region among the subtypes. In *Tsurushita*, the following 5' RACE primers are disclosed as examples:

5   (i)   5'-GCCAGTGGATAGACTGATGG- (SEQ ID NO:129) (for cloning of mouse γ1, γ2a, γ2b and γ3 H-chains)

        (ii)   5'-GATGGATACAGTTGGTGCAGC- (SEQ ID NO:130) (for cloning of mouse κ light chains).

PCR-amplified V gene fragments can be directly cloned into a plasmid vector, for example, using the Zero Blunt TOPO PCR Cloning Kit (Invitrogen), and

10   their DNA sequences determined.   The obtained sequences should be confirmed by, for example, comparing their encoding amino acid sequences with those of the target monoclonal antibody determined by the N-terminal amino acid sequencing, using, for example a Model 241 Protein Sequencer (Hewlett-Packard, CA).   Typically, the determination of at least 15-20 amino acid residues at the N-terminus of the target

15   antibody, for example, by Edman degradation, is sufficient to confirm the authenticity of the cloned DNA sequences.   *Tsurushita* cautions that when glutamine, which is one of the two most common N-terminal amino acid in mouse, is the N-terminal amino acid, it might have been converted to pyroglutamine and blocks the sequencing at the N-terminus.   In that case, it is necessary to deblock the

20   N-terminus to obtain the sequence.

Three-dimensional modeling of V regions

Based on the sequences of the VH and VL regions, the framework residues of the target antibody that are potentially important for maintaining the conformational structure of the CDRs, are first identified by the method, for

25   example, described by R. Levy *et al.*, 1989, *Biochemistry* 28:7168-7175; and by B. Zilber *et al.*, 1990, *Biochemistry* 29:10032-10041.   Typically, each of the VH and VL regions is divided into 14 structurally meaningful segments, which are β strands and loop-like structures comprising the domain structure of the immunoglobulin superfamily.   The amino acid sequence of each of the segments from the target

30   antibody is aligned with the corresponding segments of antibodies of known structures, in the PDB database (*see* H.M. Berman *et al.*, 2000, *Nucleic Acids Res.* 28:235-342).   By multiple sequence alignment, a corresponding segment having the

highest sequence homology to each of the target segment is selected and the
three-dimensional model of the V-region is constructed.   In order to optimize the
structure, the model is subjected to multiple cycles of conjugate gradient energy
minimization (*e.g.*, using ENCAD, or as described by Press *et al.*, 1990, in

5   "*Numerical Recipes*, Cambridge University Press, Cambridge; AMBER by Weiner *et
al.*, 1981, *J. Comp. Chem.* 2:287-303; 3D-JIG-SAW available at
BioMolecularModelling or "BMM" web site run by Cancer Research UK; or
SWISS-MODEL available at ExPASy Proteomics Server web site run by Swiss
Institute of Bioinformatics, Geneva).

10   **Selection of human frameworks**

          In parallel with modeling the structure of the V regions, the amino acid
sequences deduced from the cDNA cloning of the mouse VH and VL regions,
respectively, are compared to human V region sequences in the databases, for
example, the Kabat database (*see* Johnson *et al.*, 2000, *Nucleic Acids Res.*

15   28:214-218.), GenBank, and so forth.   Human framework regions that have overall
sequence identity of at least about 65%, at least about 70%, at least about 75%, at
least about 80%, at least about 85%, at least about 90%, or at least 95% identity, with
the mouse sequence, can be searched using, for example, the Smith-Waterman
algorithm (by Gusfield, 1997, in "*Algorithms on Strings, Trees, and Sequences*",

20   Cambridge University Press, Cambridge), or BLAST (by Karlin *et al.*, 1990, *Proc.
Natl. Acad. Sci. USA* 87:2264-2268), and the like.   These human sequences may be
based on cDNA-based and protein-derived sequences; however, the use of germline
is often preferable as it may be useful in eliminating potential immunogenicity
associated with somatic hypermutations in cDNA-based, protein-derived sequences.

25   In the alternative, as described in Queen *et al.* (1989, *supra*), the use of a consensus
framework sequence can also identify and remove such hypermutated residues in the
framework obtained from cDNA-based or protein-derived sequences.   In the case
where a germline VH segment is used as an acceptor framework, VH segments
encoded on chromosome 14, rather than 15 and 16, should be used as only those on

30   chromosome 14 produce functional VH regions.

     Design of humanized V regions

          According to Queen *et al.* (1989, *supra*), it is necessary to identify framework

amino acids within about 4-6 Å of the CDRs as these residues are considered to be potential key framework residues that support the correct CDR structures. Such a process can be achieved using a computer program, such as RASMOL available at Molecular Visualization Freeware web site supported by National Science

5   Foundation (NSF), that calculates interatomic distances from the atomic coordinates or, through manual inspection of a computer model. If amino acids at key framework positions are different between mouse donor and human acceptor sequences, those of mouse donor usually replace the human residues. However, if such residues have minimal contribution to support the CDR structures, the

10   corresponding human residues are typically used. Also, if the selected human acceptor contains "atypical" amino acids, which occur in less than about 10-20% of the V region sequences, they may be the result of somatic hypermutation during affinity maturation and should be replaced with the donor residues in order to avoid potential immunogenicity in humans.

15   In addition, other factors, such as residues of potential N-linked glycosylation signals, need to be carefully considered in order to design humanized V regions (*see Tsurushita* for details).

       Humanized antibodies may contain a human constant region or a portion thereof from the human κ or λ light chain, and/or the γ1, γ2, γ3, γ4, μ, α1, α2, δ, or ε

20   heavy chain of human antibodies, or variants thereof, depending on the effector functions required or to be eliminated for therapeutic uses. For example, a Fc portion of the constant region containing a mutation may be fused to the variable region of the chimeric or humanized antibody of the present invention so as to reduce the binding of the antibody to Fc receptors and/or to reduce its ability to fix

25   complement (*see*, for example, Winter *et al.*, GB 2,209,757 B; Morrison *et al.*, WO 89/07142, Morgan *et al.*, WO 94/29351). Such manipulations of antibody molecules can be carried out by recombinant DNA technology as described in Section 5.2.

       Preferably the resulting chimeric or humanized antibody has the same

30   specificity as the non-human donor antibody and an affinity similar to or at least about 1/3, at least about 1/2, or at least about 2/3, of that of the non-human donor antibody. In another aspect, the resulting chimeric or humanized antibody has an affinity constant of at least about $1 \times 10^7 \, M^{-1}$, preferably at least about $1 \times 10^8 \, M^{-1}$,

and most preferably at least about $1 \times 10^9 \, M^{-1}$.

In addition to the general protocol described above, antibodies can be
humanized using a variety of techniques known in the art including, for example,
CDR-grafting (EP 239,400; PCT publication WO 91/09967; U.S. Patent Nos.
5   5,225,539; 5,530,101 and 5,585,089), veneering or resurfacing (EP 592,106; EP
519,596; Padlan, Molecular Immunology, 28(4/5):489-498, 1991; Studnicka et al.,
Protein Engineering, 7(6):805-814, 1994; Roguska et al., Proc Natl. Acad. Sci. USA,
91:969-973, 1994), and chain shuffling (U.S. Patent No. 5,565,332), all of which are
hereby incorporated by reference in their entireties.

10   **5.3.2.   Additional considerations for preparing humanized antibodies as
            pharmaceuticals**

To offer humanized antibodies as pharmaceuticals, an efficient and consistent
production system therefor needs to be prepared.   For example, an appropriate
expression vector for humanized antibodies is prepared by inserting H- and L-chain
15   sequences, and a high-productivity cell line transfected with the expression vector
can be obtained as a seed cell for a master cell bank (MCB), which serves as a stable
and semi-permanent source for a working cell bank (WCB).   Humanized antibodies
can be then prepared by culturing working cells from the WCB and collecting the
culture medium.

20   Various expression vectors with appropriate regulatory genes can be used for
the preparation of such a production cell line.   As a host cell, those commonly used
for expressing mammalian proteins can be used for the expression of humanized
antibodies.   Examples of such host cells include, but are not limited to, Chinese
Hamster Ovary (CHO) cells, SP2/0-Ag14.19 cells, NSO cells, and the like.   The
25   productivity of humanized antibodies can be maximized by selecting the best
combination of an expression vector and a host cell.   Furthermore, the composition
of culture media should be explored in order to select suitable media, from various
serum-free culture media and supplements, so that the expression of humanized
antibodies by the host cell can be optimized.

30   Based on the efficiency and the final yield, the humanized antibodies
produced by the host cell can be purified from the culture supernatant using various
methods well known in the art, including affinity chromatography, ion-exchange

chromatography, hydrophobic interaction chromatography, and the like.

5.4. Pharmaceutical Composition and Therapeutic Uses

The present invention provides a pharmaceutical composition comprising the
humanized antibody or an antigen-binding fragment thereof, described above, that

5   immunospecifically recognizes human α9 integrin.   The pharmaceutical
composition comprising the humanized antibody of the present invention as an active
ingredient can be used as an agent for preventing and/or treating a disorder or disease
that is associated with α9 integrin, including, but not limited to, cancer, *e.g.*, the
growth or metastasis of cancer cells, and an inflammatory disease, *e.g.*, rheumatoid

10   arthritis, osteoarthritis, hepatitis, bronchial asthma, fibrosis, diabetes mellitus,
arteriosclerosis, multiple sclerosis, granuloma, an inflammatory bowel disease
(ulcerative colitis and Crohn's disease), an autoimmune disease, and the like.

The pharmaceutical composition comprising the humanized antibody of the
present invention can also be used to treat chronic rejection after organ

15   transplantation, and an autoimmune disease such as systemic autoimmune disease,
erythematosus, uveitis, Behcet's disease, polymyositis, glomerular proliferative
nephritis, sarcoidosis, and the like.

The preventive and/or therapeutic agent for preventing or treating the
disorders or diseases described above, comprising the humanized antibody of the

20   present invention, has low toxicity and can be administered to humans orally or
parenterally, directly as a liquid preparation by mixing in a suitable solvent, or as a
pharmaceutical composition in an appropriate dosage form.

The pharmaceutical composition used for the administration described above
contains the aforesaid antibody or salts thereof and pharmaceutically acceptable

25   carriers, diluents or excipients.   Such a composition is provided in a dosage form
suitable for oral or parenteral administration.

The dose may vary depending upon the age and the size of a subject to be
administered, target disease, conditions, route of administration, and the like.   When
the antibody is used for preventing and/or treating, for example, rheumatoid arthritis

30   in an adult patient, it is advantageous to intravenously administer the antibody of the
present invention normally at a single dose of about 0.01 to about 20 mg/kg body
weight, preferably about 0.1 to about 10 mg/kg body weight, and more preferably

about 0.1 to about 5 mg/kg body weight, approximately 1 to 5 times per day, preferably approximately 1 to 3 times per day.   In other parenteral administration and oral administration, the antibody can be administered in a dose corresponding to the dose given above.   When the condition is especially severe, the dose may be

5   increased according to the condition.

Various delivery systems are known and can be used to administer the pharmaceutical composition of the invention, e.g., encapsulation in liposomes, microparticles, microcapsules, recombinant cells capable of expressing the mutant viruses, receptor mediated endocytosis (see, e.g., Wu and Wu, 1987, J. Biol. Chem.

10   262:4429 4432).   Methods of introduction include but are not limited to intradermal, intramuscular, intraperitoneal, intravenous, subcutaneous, intranasal, epidural, and oral routes.   The compounds may be administered by any convenient route, for example by infusion or bolus injection, by absorption through epithelial or mucocutaneous linings (e.g., oral mucosa, rectal and intestinal mucosa, etc.) and may

15   be administered together with other biologically active agents.   Administration can be systemic or local.   Pulmonary administration can also be employed, e.g., by use of an inhaler or nebulizer, and formulation with an aerosolizing agent.

In a specific embodiment, it may be desirable to administer the pharmaceutical compositions of the invention locally to the area in need of treatment;

20   this may be achieved by, for example, and not by way of limitation, local infusion during surgery, topical application, e.g., in conjunction with a wound dressing after surgery, by injection, by means of a catheter, by means of a suppository, by means of nasal spray, or by means of an implant, said implant being of a porous, non porous, or gelatinous material, including membranes, such as sialastic membranes, or fibers.

25   In one embodiment, administration can be by direct injection at the site (or former site) infected tissues.

In another embodiment, the pharmaceutical composition can be delivered in a vesicle, in particular a liposome (see Langer, 1990, Science 249:1527-1533; Treat et al., in Liposomes in the Therapy of Infectious Disease and Cancer, Lopez Berestein

30   and Fidler (eds.), Liss, New York, pp. 353-365 (1989); Lopez-Berestein, ibid. , pp. 317-327; see generally ibid.).

In yet another embodiment, the pharmaceutical composition can be delivered in a controlled release system.   In one embodiment, a pump may be used (see

Langer, supra; Sefton, 1987, CRC Crit. Ref. Biomed. Eng. 14:201; Buchwald et

al.,1980, Surgery 88:507; and Saudek et al., 1989, N. Engl. J. Med. 321:574).   In

another embodiment, polymeric materials can be used (see Medical Applications of

Controlled Release, Langer and Wise (eds.), CRC Pres., Boca Raton, Florida (1974);

5   Controlled Drug Bioavailability, Drug Product Design and Performance, Smolen and

Ball (eds.), Wiley, New York (1984); Ranger and Peppas, J. Macromol. Sci. Rev.

Macromol. Chem. 23:61 (1983); see also Levy et al., 1985, Science 228:190; During

et al., 1989, Ann. Neurol. 25:351; Howard et al., 1989, J. Neurosurg. 71:105).   In

yet another embodiment, a controlled release system can be placed in proximity of

10   the composition's target, thus requiring only a fraction of the systemic dose (see, e.g.,

Goodson, in Medical Applications of Controlled Release, supra, vol. 2, pp. 115-138

(1984)).   Other controlled release systems are discussed in the review by Langer

(Science 249:1527-1533 (1990)).

Examples of the composition for oral administration include solid or liquid

15   dosage forms, specifically, tablets (including dragees and film-coated tablets), pills,

granules, powdery preparations, capsules (including soft capsules), syrup, emulsions,

suspensions, etc.   Such a composition is manufactured by publicly known methods

and contains a vehicle, a diluent or an excipient conventionally used in the field of

pharmaceutical preparations.   Examples of the vehicle or excipient for tablets are

20   lactose, starch, sucrose, magnesium stearate, and the like.

The injectable preparations may include dosage forms for intravenous,

subcutaneous, intracutaneous and intramuscular injections, drip infusions, etc.

These injectable preparations may be prepared by methods publicly known.   The

injectable preparations may be prepared, e.g., by dissolving, suspending or

25   emulsifying the antibody or its salt described above in a sterile aqueous medium or

an oily medium conventionally used for injections.   As the aqueous medium for

injections, there are, for example, physiological saline, an isotonic solution

containing glucose and other auxiliary agents, etc., which may be used in

combination with an appropriate solubilizing agent such as an alcohol (e.g., ethanol),

30   a polyalcohol (e.g., propylene glycol, polyethylene glycol), a nonionic surfactant

[e.g., polysorbate 80, HCO-50 (polyoxyethylene (50 mol) adduct of hydrogenated

castor oil)], etc.   As the oily medium, there are employed, e.g., sesame oil, soybean

oil, etc., which may be used in combination with a solubilizing agent such as benzyl

benzoate, benzyl alcohol, etc.   The injection thus prepared is preferably filled in an appropriate ampoule.   The suppository used for rectal administration may be prepared by blending the aforesaid antibody or its salt with conventional bases for suppositories.

5   Advantageously, the pharmaceutical compositions for oral or parenteral use described above are prepared into dosage forms in a unit dose suited to fit a dose of the active ingredients.   Such dosage forms in a unit dose include, for example, tablets, pills, capsules, injections (ampoules), suppositories, etc.   The amount of the aforesaid antibody contained is generally about 5 to 500 mg per dosage form in a unit

10   dose; especially in the form of injection, it is preferred that the aforesaid antibody is contained in about 5 to 100 mg and in about 10 to 250 mg for the other dosage forms.

Each composition described above may further contain other active components unless formulation causes any adverse interaction with the antibodies described above.

15   The present invention also relates to an inhibitor and/or promoter for cell and/or tissue remodeling, which comprises an α9 integrin-binding functional molecule (e.g., OPN, VCAM-1, tenascin-C, fibronectin, pp-vWF, tTG etc.) as an active ingredient; and a method for inhibiting and/or promoting cell and/or tissue remodeling, which comprises contacting the α9 integrin-expressing cell and/or tissue

20   (e.g., a tumor cell, neutrophil, smooth muscle, etc.) with the α9 integrin-binding functional molecule.   The dose, method for administration, pharmaceutical preparation, etc. of the active ingredient in such a therapeutic agent can be appropriately determined by referring to the foregoing description of medicaments comprising the humanized antibodies of the present invention.

25   As described above, the present invention further provides a method for preventing or treating a disorder or disease that is associated with or involves α9 integrin, said method comprising administering an effective amount of at least one of the humanized antibodies of the present invention to a subject in need thereof.

5.5. Diagnostic Uses

30   The pharmaceutical composition comprising the humanized antibody of the present invention can be used as a diagnostic agent for cancer, e.g., the growth or

metastasis of cancer cells, and an inflammatory disease, e.g., rheumatoid arthritis,
osteoarthritis, hepatitis, bronchial asthma, fibrosis, diabetes mellitus, cancer
metastasis, arteriosclerosis, multiple sclerosis, granuloma, etc., or as a diagnostic
agent for chronic rejection after organ transplantation, an autoimmune disease such

5   as systemic autoimmune disease, erythematosus, uveitis, Behcet's disease,
polymyositis, glomerular proliferative nephritis, sarcoidosis, and so forth.   The
humanized antibodies of the present invention are capable of specifically recognizing
the α9 integrin and hence can be used to quantify the α9 integrin in a test fluid,
especially for quantification by the sandwich immunoassay, competitive assay,

10   immunometry, nephrometry, etc., immunostaining, or the like.   In applying these
immunological methods to the assay methods of the present invention, it is not
required to set forth any particular conditions, procedures, etc.   It is sufficient to
construct assay systems by adding ordinary technical consideration in the art to
conventional conditions and procedures.   For details of these general technical

15   means, reference can be made to reviews, texts or the like.

      As described above, the α9 integrin can be quantified with high sensitivity by
using the antibodies of the present invention.   The humanized antibodies of the
present inventions are particularly useful for diagnosing various diseases associated
with the α9 integrin by applying the method for quantifying the α9 integrin *in vivo*.

20   For instance, where an increase or decrease in the expression level of the α9 integrin
is detected, it can be diagnosed that it is highly likely that one now suffers from
diseases associated with the α9 integrin, e.g., cancer or an inflammatory disease, or it
is highly likely that one will suffer from these diseases in the future.   Thus, the
present invention also provides a method for diagnosing a disorder or disease

25   associated with or involve α9 integrin in a subject, said method comprising
administering an effective amount of at least one of the humanized antibodies of the
present invention or both to a subject in need thereof.   Required dosages for such an
in vivo diagnosis may be less than those required for therapeutic uses and can be
determined by one skilled in the art according to routine procedures.

30   The humanized antibodies of the present invention can also be used for
specifically detecting the α9 integrin present in a test fluid such as a body fluid, a
tissue, etc.   The humanized antibodies can also be used for preparation of antibody
columns for purification of the α9 integrin, for detection of the α9 integrin contained

in each fraction upon purification or for analysis of behaviors of the α9 integrin in cells to be tested.

6. EXAMPLES

5   The following examples illustrate the preparation of monoclonal antibodies that immunospecifically recognize human and/or mouse α9 integrin, the sequencing of the variable regions of the monoclonal antibodies, the epitope mapping and other characterization of the antibodies and the chimerization and the humanization of such antibodies, as well as the characterization of the resulting chimeric and humanized

10   antibodies.   These examples should not be construed as limiting.

6.1. Preparation of Mouse Antibody Against Human α9 Integrin

        Mouse monoclonal antibodies against human α9 integrin were prepared according to the subtractive immunization method (by Williams C.V., *et al.*, 1992, *Biotechniques* 12:842-847).   Briefly, three Balb/c mice were injected

15   intraperitoneally with CHO-K1 cells at 4×10^6 per mouse.   In the following two days, the mice received 4 mg/mouse of cyclophosphamide intraperitoneally.   At two weeks after the cyclophosphamide injection, the mice were injected intraperitoneally with 2×10^6 cells/mouse of CHO-K1 cells expressing human α9 integrin (Human α9/CHO-K1 cells), followed by another intraperitoneal injection of the same cells at

20   3×10^6 cell/mouse two weeks later.   Hybridomas were prepared by the methods well known in the art (*see*, for example, Harlow et al., Antibodies: A Laboratory Manual, (Cold Spring Harbor Laboratory Press, 2nd ed. 1988); Hammerling, et al., in: Monoclonal Antibodies and T-Cell Hybridomas, pp. 563-681 (Elsevier, N.Y., 1981). Hybridoma clones producing monoclonal antibodies that were immunospecifically

25   reactive with Human α9/CHO-K1 cells but not with CHO K1 cells expressing human α4 integrin were established and five hybridoma clones (*i.e.*, 1K11, 21C5, 24I11, 25B6 and 28S1) producing monoclonal antibodies immunospecifically recognizing human α9 integrin were isolated.

6.2. Epitope Analysis for Anti-Human α9 Integrin Monoclonal Antibodies

30   Twelve-residue polypeptides, starting from N-terminal of human α9 integrin

and every three residues thereafter (*i.e.*, amino acid residues 1-12, 4-15, 7-18, and so forth) were prepared and coupled to a cellulose membrane via C6-spacer and 2 βAla residues at 5 nmol/spot.   The membrane was blocked with a blocking buffer (milk/0.05% Tween20 in PBS) and reacted with 10 ml of solution containing 1.0

5   μg/ml of each of the anti-human α9 integrin monoclonal antibodies (*i.e.*, 1K11, 21C5, 24I11 and 25 B6, respectively) labeled with peroxidase for three hours at room temperature.   After washing with T-TBS, the membrane was reacted with enhanced chemiluminescence (ECL) detecting reagent for 1 minute at room temperature.   The luminescence emitted as a result of the enzymatic reaction is measured and epitopes

10   of the antibodies were determined based on the luminescence intensities.   As a control, Y9A2 (*see* Wang *et al.*, 1996, *Am J Respir Cell Mol Biol* 15, 664-672), a commercially available monoclonal antibody against human α9 integrin, was used.

Table 1 below shows the result of the epitope mapping, which indicated that the monoclonal antibodies isolated by the present inventors have epitopes that are

15   distinct from that of Y9A2.

6.3. CDR Analysis of Anti-Human α9 Integrin Antibodies

The amino acid sequences of CDRs of the monoclonal antibodies (*i.e.*, 1K11,
21 C5, 24I11, 25B6 and 28S1) were determined by reverse transcription of the
mRNA extracted from the corresponding hybridomas to prepare cDNAs. Using the
cDNAs as templates, the variable regions of the H-chains and L-chains were
extended and amplified by PCR using ScFv-cloning primers (Light Primer Mix and
Heavy Primer Mix; by Amersham Biosciences Corp., IL). The PCR products were
cloned into pCRII TOPO vector, sequenced and the amino acid sequences were
determined. This process was repeated three times for each antibody. The results
are shown in Table 2.

Table 2

CDRs	1K11	21C5	24I1	25B6	28S1
CDRH1	DYNMD (SEQ ID NO:32)	DYYMY (SEQ ID NO:42)	DTYVH (SEQ ID NO:4)	SYGVH (SEQ ID NO:52)	GYGVN (SEQ ID NO:62)

6.4. Cell Adhesion Inhibitory Activity

(1) Since it is known that cell adhesion involves the binding of α9 integrin to

its ligands, *i.e.*, various ECMs, including OPN, fibronectin , Tenascin-C, VCAM-1, and the like, the isolated anti-human α9 integrin antibodies were examined for their cell adhesion inhibitory activity.

5   Briefly, hOPN(RAA)N-half was prepared as a Glutathione S-transferase (GST)-fusion protein by isolating from *E. coli* host cells an N-terminal portion down to the thrombin-cleavage site of OPN, in which the GRD sequence has been replaced with the RAA sequence, and cleaving the GST portion with Precision protease (Amersham Biosciences).   VCAM-1 was purchased from R&D Systems, Inc. (Minneapolis, MN).   Tenascin-C and human fibronectin were prepared by

10   synthesizing polypeptides containing AEIDGIEL (SEQ ID NO:92); the α9 integrin-binding region of Tenascin-C) and CPEDGIHELFP (SEQ ID NO:93); the α9 integrin-binding region of human fibronectin), respectively, and subsequently attaching them to bovine serum albumin (BSA).   For human α9 integrin, CHO-K1 cells that abundantly expressed human α9 integrin (Human α9/CHO-K1) were used.

15   Fifty microliters of Tenascin-C, fibronectin, VCAM-1 or hOPN(RAA)N-half were added to a 96-well plate at 1.25-5.0 μg/ml and incubated at 37°C for 1 hour to coat the plate.   After blocking the plate with a blocking solution (0.5% BSA/PBS) and washing it with PBS once, the mixture of human α9/CHO-K1 cells (1.0x10^5 cells/ml) and the isolated monoclonal antibodies (10 g/ml) in 0.25% BSA-Minimum

20   Essential Media (MEM) was added to the plate at 200 μl/well and incubated at 37°C for 1 hour under 5% CO_2.   Non-adherent cells were rinsed off with PBS and adherent cells were fixed and stained with 0.5% Crystal Violet (by WAKO, Osaka, Japan)/20% methanol.   The stained cells were allowed to stand at room temperature for 30 minutes and 20% acetic acid solution was added thereto to effect dissolution.

25   The adhesion activity was quantified by measuring OD at 590 nm wavelength.

As shown in Fig. 16, the cell adhesion involving Tenascin-C was inhibited by 21C5, 24I11, 25B6 and 28S1, but not by 1K11.   The cell adhesion involving fibronectin was inhibited by 21C5, 25B6 and 28S1 and by 24I11 to a less degree, but no inhibition was observed with 1K11.   The cell adhesion involving VICAM-1 was

30   inhibited by 21C5, 24I11, 25B6 and 28S1, but not by 1K11.   Likewise, the cell adhesion involving hOPN(RAA)N-half was inhibited by 21C5, 24I11, 25B6 and 28S1, but not by 1K11.

(2) Since α4 integrin and α9 integrin have many common ECM ligands, the presence of both anti-α4 integrin and anti-α9 integrin antibodies is expected to enhance the cell adhesion inhibitory activity.   Thus, the effect of the both types of antibodies in combination was examined *in vitro* for a possible inhibitory effect on

5   metastatic cancer, based on the cell adhesion between human melanoma cells (G361) expressing α4 integrin as well as α9 integrin and VCAM-1 (1.25 μg/ml) as an ECM; a rat monoclonal antibody, P1H4 (Cat. No. MAB16983Z, Chemicon International Inc., CA) was used as an anti-human α4 integrin antibody.

As shown in Fig. 17, the adhesion involving VCAM-1 was not inhibited by

10   any of the anti-human α9 integrin antibodies alone, but was inhibited by the positive control (Y9A2), 21C5 and 24I11, in the co-presence of the anti-human α4 integrin antibody.   Since cells expressing many α9 integrin molecules usually express α4 integrin molecules also, this result indicates that the inhibition of cell adhesion can be effectively achieved by the combination use of anti-human α9 integrin antibody

15   and anti-human α4 integrin antibody, thereby enhancing the suppression of various disorders and diseases, including metastatic cancer involving these integrin molecules.

6.5. Use of Anti-Human α9 Integrin Antibodies in FACS Analysis

Whether the anti-human α9 integrin antibodies were usable for FACS was

20   examined using Human α9/CHO-K1 cells, CHO-K1 cells and human neutrophils endogenously expressing the α9 integrin.   In human neutrophils, FACS analysis was conducted at the cell count of 1.0×10^5 and antibodies were reacted on ice. Non-specific reaction with the Fc receptor was blocked with 50% goat serum. FITC-labeled anti-mouse IgG antibody was used as a secondary antibody.   As a

25   result (*see* Figs. 20a, 20b and 20c), all of the anti-human α9 integrin antibodies could detect the α9 integrin on Human α9/CHO-K1 and human neutrophils.   None of the antibodies reacted with Human α4/CHO-K1 cells (*see* Figs. 20a, 20b and 20c). These results revealed that all of the anti-human α9 integrin antibodies could detect the human α9 integrin proteins expressed on cells using FACS.

6.6. Therapeutic Effects of Anti-α9 Integrin Antibody

Therapeutic effects of anti-α9 integrin antibodies were examined in a mouse system.

The anti-mouse α9 integrin monoclonal antibodies (11L2B, 12C4'58, 18R18D and 55A2C) were prepared substantially in the same manner as described for mouse anti-human α9 integrin antibodies (*see* Section 6.1, *supra*), except that hamsters were immunized with CHO-K1 cells expressing mouse α9 integrin (mouse α9/CHO-K1 cells) and the resulting monoclonal antibodies that reacted with mouse α9/NIH3T3 cells but not with mouse α4/NIH3T3 were selected.

6.6.1. Therapeutic effect on hepatitis

WO 02/081522 discloses that hepatitis can be treated by inhibiting the OPN functions.   Accordingly, therapeutic effects of anti-α9 integrin antibody was studied in a mouse hepatitis model using a hamster anti-mouse α9 integrin antibody, 11L2B, and a rat anti-mouse α4 integrin antibody, R1-2 (Pharmingen).   The blood AST and ALT levels in the mice were measured using GPT/ALT-PIII and GOT/AST-PIII (Fuji Film), 12 hours after an intravenous injection of 200 μg of concanavalin A (Con A) (Vector).   Three hours before the Con A injection, 200 μg of the antibody were administered.   As shown in Fig. 18, the AST and ALT levels were found to be decreased by the anti-α9 integrin antibody, and the therapeutic effects could be noted.   In addition, the therapeutic effects could be boosted by concomitant use with the anti-α4 integrin antibody.   The results revealed that hepatitis could be treated by the anti-α9 integrin antibody.

6.6.2. Effect of anti-α9 integrin antibodies on growth of mouse cancer cell line

Murine melanoma cell line B16-BL6 expresses abundant α9 integrin. Accordingly, cell growth inhibitory activities of the established anti-mouse α9 integrin antibodies against cancer cells were examined.

The B16-BL6 cells were prepared on a 96-well plate for cell culture (Becton Dickinson) at 5 x 10⁴ cells/mL in 10% FCS/DMEM.   After 10 μg/ml of the anti-mouse α9 integrin antibody and anti-mouse α4 integrin antibody were added,

100 μL each of the cell-antibody suspension was added to each well.   Incubation
was conducted at 37°C for 24 hours under 5% CO_2, and 10 μL each of Cell Counting
Kit 8 (Dojin Kagaku Kenkyu-sho) was added, followed by incubation at 37°C for an
hour under 5% CO_2.   Absorbance at O.D. 450 was measured and the cell count was
5   quantitatively analyzed.   As shown in Fig. 19, 12C4'58 gave the highest inhibitory
activity and inhibited the growth of B16-BL6 cells by about 35%.   Both 55A2C and
R1-2 could inhibit the growth by about 20%.

Next, for analysis of inhibitory effects against cell growth under conditions
closer to the in vivo conditions, VCAM-1 was immobilized on a solid phase and
10   assayed in a similar fashion.   VCAM-1 is a ligand for α9 integrin and a
recombinant soluble form of VCAM-1 protein, rhVCAM-1-Fc chimera (Roche), was
used.   Using the rhVCAM-1-Fc chimera immobilized on a solid phase with 10
μg/mL, non-specific reaction was blocked with 0.5% BSA/PBS.   The chimera was
added in a concentration of 10 μg/ml in single use of the antibody, and in 5 μg
15   each/ml in concomitant use.   Thereafter, the same procedures as in Fig. 19 were
followed.   As a result, the effect was not obtained at all or only an imperceptible
effect was obtained by single administration of 12C4'58 and by single use of the α4
inhibitory antibody clone R1-2, whereas in simultaneous administration of 12C4'58
with R1-2 the cell growth inhibitory effect showed a marked increase by about 20%,
20   as shown in Fig. 21.

6.6.3.   Therapeutic effect of anti-α9 integrin in mouse rheumatoid arthritis model

Seven-week old female mice (Balb/c) (3 mice per group) were injected
intraperitoneally with the hamster anti-mouse α9 integrin antibody (55A2C), or
25   normal hamster IgG (NHG) at 400 μg/mouse.   After 24 hours, 2 mg/mouse of the
arthritis-inducing cocktail of type II collagen-specific monoclonal antibody
(Chondrex Inc.) was injected intravenously.   After 72 hours, 400 μg/mouse of
55A2C or NHG as well as 50 μg/mouse of LPS were injected intraperitoneally.   The
mice were observed from 3 days before the LPS injection until 6 days after the LPS
30   injection and the levels of arthritis were scored according to the method by Wood et
al. (1969, Int. Arch. Allergy Appl. Immunol. 35:456).   The result is shown in Fig. 22.
The mice injected with control NHG had a high score and developed rheumatoid

arthritis, whereas in those injected with anti-mouse α9 integrin antibody, the
development of rheumatoid arthritis was completely blocked.   Thus, anti-α9
integrin antibodies were indicated to have prophylactic and therapeutic effects on
rheumatoid arthritis.

5   6.7. <u>**Humanization of Non-Human Antibodies**</u>

6.7.1. Cloning and sequencing of mouse 24I11 V genes

Mouse 24I11 hybridoma cells were grown in TIL Media I
(Immuno-Biological Laboratories, Gunma, Japan) containing 10% fetal bovine
serum (FBS; HyClone, Logan, UT) at 37°C in a 7.5% CO_2 incubator.   Total RNA
10   was extracted from approximately 3 x 10^6 hybridoma cells using TRIzol reagent
(Invitrogen, Carlsbad, CA) according to the supplier's protocol.   Oligo dT-primed
cDNA was synthesized using the GeneRacer Kit (Invitrogen) following the supplier's
protocol.   The variable region cDNAs for 24I11 heavy and light chains were
amplified by polymerase chain reaction (PCR) with Phusion DNA polymerase (New
15   England Biolabs, Beverly, MA) using   primers that anneal respectively to the mouse
gamma-1 and kappa chain constant regions, and a GeneRacer 5' primer
(5'-CGACTGGAGCACGAGGACACTGA-) (SEQ ID NO:94) provided in the
GeneRacer Kit.   For PCR amplification of heavy chain variable region (VH), the
primer has the sequence 5'-GCCAGTGGATAGACAGATGG- (SEQ ID NO:95).
20   For PCR amplification of light chain variable region (VL), the   primer has the
sequence 5'-GATGGATACAGTTGGTGCAGC- (SEQ ID NO:96).   The amplified
VH and VL cDNAs were subcloned into the pCR4Blunt-TOPO vector (Invitrogen)
for sequence determination.   DNA sequencing of the variable regions was carried
out at Tocore (Menlo Park, CA).   Several heavy and light chain clones were
25   sequenced and unique sequences homologous to typical mouse heavy and light chain
variable regions were identified.   The consensus cDNA sequences along with
deduced amino acid sequences of 24I11 VH and VL are shown in Figs. 1 and 2,
respectively.

6.7.2. Construction of chimeric 24I11 IgG1/κ antibody

30   A gene encoding 24I11 VH was generated as an exon including a splice donor
signal and appropriate flanking restriction enzyme sites by PCR using 24I11 VH

cDNA as a template,

5'-GGGACTAGTACCACCATGAAATGCAGCTGGGTTATCTTC- (SEQ ID

NO:97) (SpeI site is underlined) as a 5' primer, and

5'-GGGAAGCTTAGAGGCCATTCTTACCTGAGGAGACGGTGACTGAGGTTC

5   C- (SEQ ID NO:98) (HindIII site is underlined) as a   primer (Fig. 3).   Likewise, a

gene encoding 24I11 VL was generated as an exon including a splice donor signal

and appropriate flanking restriction enzyme sites by PCR using 24I11 VL cDNA as a

template, 5'-GGGGCTAGCACCACCATGAGTGTGCCCACTCAACTCCTG-

(SEQ ID NO:99) (NheI site is underlined) as a 5' primer, and 5'-

10   GGGGAATTCTGAGAAGACTACTTACGTTTTATTTCCAGCTTGGTCCCCCC-

(SEQ ID NO:100) (EcoRI site is underlined) as a   primer (Fig. 4).   The splice

donor signals of the 24I11 VH and VL exons were derived from the mouse germline

JH4 and Jκ2 sequences, respectively.   PCR-amplified fragments were gel-purified

using QIAquick Gel Extraction Kit (Qiagen, Valencia, CA), digested with SpeI and

15   HindIII (for VH) or NheI and EcoRI (for VL), and cloned into a mammalian

expression vector carrying human gamma-1 and kappa constant regions for

production of chimeric 24I11 IgG1/κ antibody.   The schematic structure of the

resulting expression vector, pCh24I11, is shown in Fig. 5.

6.7.3.   Generation of humanized 24I11 V genes

20   Humanization of the 24I11 variable regions was carried out as outlined by

Queen et al. (Proc. Natl. Acad. Sci. USA 86: 10029-10033, 1989).   First, a

molecular model of the 24I11 variable regions was constructed with the aid of

computer programs.   Next, based on a homology search against human variable

region sequences, the human amino acid sequence encoded by the nucleotide

25   sequence of GenBank Accession No. X65891, which has a high homology [72.4%

(63/87) amino acid identity in the FRHs] to 24I11 VH, was chosen as an acceptor to

provide the frameworks for humanized 24I11 VH.   Likewise, the human amino acid

sequence encoded by the nucleotide sequence of GenBank Accession No. X72441

[77.5% (62/80) amino acid identity in the FRLs] was chosen as an acceptor for

30   humanization of 24I11 VL.

At framework positions where the computer model suggested significant

contact with the complementarity determining regions (CDRs), the amino acids from

the 24I11 variable regions were substituted for the human framework amino acids.

This was done at positions 27, 28, 29, 30, 48, 66, 67 and 71 (according to Kabat numbering system; *see*, Kabat *et al.*, Sequences of Proteins of Immunological Interests, Fifth edition, NIH Publication No. 91-3242, U.S. Department of Health and Human Services, 1991) to generate humanized 24I11 (Hu24I11) VH (Fig. 6).   For

5   the light chain, replacements were made at residues 70 and 71 to generate humanized 24I11 (Hu24I11) VL (Fig. 7).   The alignments of 24I11, designed Hu24I11, and the human acceptor amino acid sequence are shown for VH in Fig. 6 and for VL in Fig. 7.

A gene encoding each of Hu24I11 VH and VL was designed as an exon
10   including a signal peptide, a splice donor signal, and appropriate restriction enzyme sites for subsequent cloning into a mammalian expression vector.   The splice donor signals of the Hu24I11 VH and VL exons were derived from the human germline JH4 and Jκ1 sequences, respectively.   The signal peptide sequences in the Hu24I11 VH and VL exons were derived from the corresponding mouse 24I11 VH and VL
15   sequences, respectively.   The Hu24I11 VH and VL genes were constructed by extension and PCR amplification of several overlapping synthetic oligonucleotide primers using ThermalAce DNA polymerase (Invitrogen) as outlined by He et al. (J. Immunol. 160: 1029-1035, 1998).   The oligonucleotides used for construction of Hu24I11 VH and VL genes are listed in Figs. 8 and 9, respectively.   The location of
20   the oligonucleotides in the Hu24I11 VH and VL genes is shown in Figs. 10 and 11, respectively.   PCR-amplified fragments were gel-purified using QIAquick Gel Extraction Kit (Qiagen) and cloned into pCR4Blunt-TOPO vector for sequence determination.   After digestion with SpeI and HindIII (for VH) or NheI and EcoRI (for VL), Hu24I11 VH and VL genes were subcloned into corresponding sites in a
25   mammalian expression vector for production in the human IgG1/κ form.   The schematic structure of the resulting expression vector, pHu24I11, is shown in Fig. 5. The nucleotide sequences of the obtained Hu24I11 VH and VL genes along with deduced amino acid sequences are shown in Figs. 12 and 13, respectively.

6.7.4.   Transient expression of chimeric and humanized 24I11 IgG1/κ

30   Chimeric and humanized 24I11 IgG1/κ antibodies were transiently expressed by transfecting pCh24I11 and pHu24I11 plasmid DNA, respectively, to HEK293 cells using polyethylenimine according to Durocher et al. (Nucl. Acids Res. 30: e9,

2002). Transiently transfected HEK293 cells were maintained for four days in DMEM containing 10% FBS at 37°C in a 7.5% CO_2 incubator. The expression level of each of Ch24I11 and Hu24I11 IgG1/κ antibodies in culture supernatant was measured by sandwich ELISA. An ELISA plate was coated overnight at 4°C with

5   100 μl/well of 1/2,000-diluted goat anti-human IgG Fcγ-chain-specific polyclonal antibodies (SouthernBiotech, Birmingham, AL) in PBS, washed with Wash Buffer (PBS containing 0.05% Tween 20), and blocked for 1 hr at room temperature with 300 μl/well of Blocking Buffer (PBS containing 2% Skim Milk and 0.05% Tween 20). After washing with Wash Buffer, 100 μl/well of samples appropriately diluted

10   in ELISA Buffer (PBS containing 1% Skim Milk and 0.025% Tween 20) were applied to the ELISA plate. Human IgG1/κ antibody purified from human myeloma serum (SouthernBiotech) was used as a standard. After incubating the ELISA plate for 2 hr at room temperature and washing with Wash Buffer, bound antibodies were detected using 100 μl/well of 1/2,000-diluted horse radish

15   peroxidase (HRP)-conjugated goat anti-human kappa chain polyclonal antibodies (SouthernBiotech). After incubating for 1 hr at room temperature and washing with Wash Buffer, color development was performed by adding 100 μl/well of ABTS substrate (bioWORLD, Dublin, OH). Color development was stopped by adding 100 μl/well of 2% oxalic acid. Absorbance was read at 405 nm.

20   **6.7.5. Characterization of humanized 24I11**

Binding of chimeric and humanized 24I11 antibodies to human α9 integrin was examined by cell ELISA. CHO-K1 stable transfectants expressing recombinant human α9 integrin on the surface (CHO/huα9; provided by Gene Techno Science) were seeded at 2×10^5 cells/well in 50 μl of F12/DMEM (HyClone)

25   containing 10% FBS in a 96-well tissue culture plate and grown overnight at 37°C in a 7.5% CO_2 incubator. For testing of binding to human α9 integrin, 50 μl of chimeric 24I11, humanized 24I11 or irrelevant human IgG1/κ myeloma antibody (SouthernBiotech) in F12/DMEM containing 10% FBS was added to each well. After incubating for 1 hr at 4°C and washing cells twice with ice-cold PBS, 100 μl of

30   1/1,000-diluted HRP-conjugated goat anti-human IgG polyclonal antibodies (SouthernBiotech) was added to each well. After incubating for 1 hr at 4°C, cells were washed three times with ice-cold PBS. For color development, 100 μl of

ABTS substrate was added.   Color development was stopped by adding 100 µl of
2% oxalic acid.   Absorbance was read at 405 nm.   The result showed that the
binding of chimeric 24I11 antibody to human α9 integrin was almost same as that of
humanized 24I11 antibody at both 0.5 and 1 µg/ml (Fig. 14).

5   Antigen binding of mouse, chimeric and humanized 24I11 monoclonal
antibodies was also examined in a FACS binding assay using CHO/huα9 cells.
Purified mouse 24I11 monoclonal antibody was provided by Gene Techno Sciences.
Approximately 8 x 10^5 CHO/huα9 cells/test were washed with FACS Binding Buffer
(PBS containing 0.5% BSA and 0.05% NaN_3) and suspended in 200 µl of FACS

10   Binding Buffer containing various amounts of test antibody.   After 30 min on ice,
the cells were washed twice with FACS Binding Buffer.   The cells stained with
mouse 24I11 were then suspended in 200 µl of 1/200-diluted FITC-labeled goat
anti-mouse IgG polyclonal antibody (SouthernBiotech) in FACS Binding Buffer.
The cells stained with chimeric or humanized 24I11 were suspended in 200 µl of

15   1/200-diluted FITC-labeled goat anti-human IgG polyclonal antibody
(SouthernBiotech) in FACS Binding Buffer.   After 30 min on ice, the cells were
washed with FACS Binding Buffer, suspended in 200 µl of FACS Binding Buffer,
and analyzed using a FACSCan flow cytometer (BD Biosciences, Franklin Lakes,
NJ).   The binding of chimeric and humanized 24I11 antibodies to CHO/huα9 cells

20   was very similar to each other in this analysis (Fig. 15).

          The results of the cell ELISA and FACS experiments using transiently
expressed antibodies suggest that humanization of mouse 24I11 antibody is
successful.

          Humanization of the other mouse anti-human α9 antibodies disclosed herein

25   (*i.e.*, 1K11, 21C5, 25B6 and 28S1) can be also carried out by employing the same
procedure described herein.   The DNA sequences and the amino acid sequences of
the VH and VL regions, respectively, of these mouse monoclonal antibodies are
summarized below.

Mouse monoclonal antibodies	DNA sequence of VH region (SEQ ID NO:)[1]	Deduced amino acid sequence of mature VH (SEQ ID NO:)[2]	DNA sequence of VL region (SEQ ID NO:)[1]	Deduced amino acid sequence of mature VL (SEQ ID NO:)
1K11	35	36	40	41
21C5	45	46	50	51
25B6	55	56	60	61
28S1	65	66	70	71

[1] The V genes of each antibody were cloned by a method using Amersham's degenerate primers.

[2] The deduced amino acid sequence starts from the 2nd residue of VH region (according to the Kabat numbering system) for each clone.

DEPOSITION

The hybridomas designated herein as 1K11, 21C5, 24I11, 25B6 and 28S1 producing mouse anti-human α9 integrin monoclonal antibodies were deposited on February 15, 2006 with International Patent Organism Depositary, National Institute of Advanced Industrial Science and Technology, located at AIST Tsukuba Central 6, 1-1, Higashi 1-chome Tsukuba-shi, Ibaraki-ken 305-8566 Japan in accordance with the Budapest Treaty on the Deposit of Microorganisms, and accorded Accession Nos. FERM BP-10510, FERM BP-10511, FERM BP-10512, FERM BP-10513 and FERM BP-10832, respectively, all of which are incorporated herein by reference in their entireties.

Throughout this specification the word "comprise", or variations such as "comprises" or "comprising", will be understood to imply the inclusion of a stated element, integer or step, or group of elements, integers or steps, but not the exclusion of any other element, integer or step, or group of elements, integers or steps.

Any discussion of documents, acts, materials, devices, articles or the like which has been included in the present specification is not to be taken as an admission that any or all of these matters form part of the prior art base or were common general knowledge in the field relevant to the present disclosure as it existed before the priority date of each claim of this application.

45

INDUSTRIAL APPLICABILITY

The humanized monoclonal antibodies of the present invention inhibit the function of α9 integrin to exhibit therapeutic effects on cancer, e.g., the growth or metastasis of cancer cells, and an inflammatory disease, e.g., rheumatoid arthritis,

5 osteoarthritis, hepatitis, bronchial asthma, fibrosis, diabetes mellitus, cancer metastasis, arteriosclerosis, multiple sclerosis, granuloma, an inflammatory bowel disease (ulcerative colitis and Crohn's disease), an autoimmune disease, and the like. The pharmaceutical composition comprising both the anti-α9 integrin antibody and anti-α4 integrin antibody of the present invention exerts more improved therapeutic effects on

10 cancer and an inflammatory disease.

9. LIST OF SEQUENCES

The sequences referenced throughout the specification are summarized below.

SEQ ID NO.	TYPE	DESCRIPTION	SEQUENCE
1	AA	OPN adhesion sequence	GRGDS

THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:

1.   A humanized antibody or an antigen-binding fragment thereof that immunospecifically recognizes human α9 integrin, comprising:

5   a H-chain comprising the amino acid sequence of SEQ ID NO:29, and at least one CDRH derived from at least one of CDRHs of a non-human antibody that immunospecifically recognizes human α9 integrin; and

a L-chain comprising the amino acid sequence of SEQ ID NO:31, and at least one CDRL derived from at least one of CDRLs of a non-human antibody that

10   immunospecifically recognizes human α9 integrin.

2.   An isolated nucleic acid molecule comprising a nucleotide sequence encoding the amino acid sequence of SEQ ID NO:29.

15   3.   The nucleic acid molecule of claim 2, wherein said nucleotide sequence has the nucleotide sequence of SEQ ID NO:28.

4.   The nucleic acid molecule of claim 2 further comprising a nucleotide sequence encoding a signal peptide.

20

5.   The nucleic acid molecule of claim 4, wherein said signal peptide comprises the amino acid sequence of SEQ ID NO:10.

6.   An isolated nucleic acid molecule comprising a nucleotide sequence encoding

25   the amino acid sequence of SEQ ID NO:31.

7.   The nucleic acid molecule of claim 6, wherein said nucleotide sequence has the nucleotide sequence of SEQ ID NO:30.

30   8.   The nucleic acid molecule of claim 6 further comprising a nucleotide sequence encoding a signal peptide.

9.   The nucleic acid molecule of claim 8, wherein said signal peptide comprises the

amino acid sequence of SEQ ID NO:17.

10.   A vector comprising the nucleic acid molecule of claim 2 or 6, or both, wherein said nucleic acid molecule is operably linked to one or more regulatory elements.

5

11.   An isolated host cell comprising the vector of claim 10.

12.   A method for preparing a humanized antibody or an antigen-binding fragment thereof, comprising culturing the host cell of claim 11 under conditions so that the humanized antibody or an antigen-binding fragment thereof is expressed, and collecting the expressed humanized antibody.

10

13.   A pharmaceutical composition comprising the humanized antibody or an antigen-binding fragment thereof of claim 1, and a pharmaceutically acceptable carrier.

15

14.   A method for preventing or treating a disorder or disease associated with α9 integrin, said method comprising administering an effective amount of the humanized antibody or an antigen-binding fragment thereof of claim 1 to a subject in need thereof.

20   15.   A method for diagnosing a disorder or disease associated with α9 integrin *in vivo*, said method comprising administering an effective amount of the humanized antibody or an antigen-binding fragment thereof of claim 1 to a subject to be examined.

20.   The humanized antibody or an antigen-binding fragment thereof of claim 1 or 25   the nucleic acid molecule of claims 2 or 6, substantially as hereinbefore described with reference to any of the Examples and/or Figures.
