ABSTRACT
The invention generally relates to methods of treating an overweight or obese subject, and treating overweight- or obesity-related conditions using non-daily administration of, e.g., a MetAP-2 inhibitor.

BACKGROUND

[0002] Obesity is a complex medical disorder of appetite regulation and metabolism resulting in excessive accumulation of adipose tissue mass. Typically defined as a body mass index (BMI) of 30 kg/m² or more, obesity is a world-wide public health concern that is associated with cardiovascular disease, diabetes, certain cancers, respiratory complications, osteoarthritis, gallbladder disease, decreased life expectancy, and work disability. The primary goals of obesity therapy are to reduce excess body weight, improve or prevent obesity-related morbidity and mortality, and maintain long-term weight loss.

[0003] Treatment modalities typically include diet and exercise programs, lifestyle management, pharmacotherapy, and surgery. Treatment decisions are made based on severity of obesity, seriousness of associated medical conditions, patient risk status, and patient expectations. Notable improvements in cardiovascular risk and the incidence of diabetes have been observed with weight loss of 5-10% of body weight, supporting clinical guidelines for the treatment of obesity that recommend a target threshold of 10% reduction in body weight from baseline values. These improvements are notable even for patients who may be overweight (with a BMI of 27 kg/m²) but also have a weight related co-morbidity such as hypertension, type 2 diabetes, dyslipidemia, or central adiposity.

[0004] However, while prescription anti-obesity medications are typically considered for selected patients at increased medical risk because of their weight and for whom lifestyle modifications (diet restriction, physical activity, and behavior therapy) alone have failed to produce durable weight loss, approved drugs have had unsatisfactory efficacy for severely obese subjects, leading to only ~3-5% reduction in body weight after a year of treatment.

[0005] Bariatric surgery may be considered as a weight loss intervention for patients at or exceeding a BMI of 40 kg/m². Patients with a BMI ≥35 kg/m² and an associated serious medical condition are also candidates for this treatment option. Recently the US-FDA has approved lapband procedures for patients exceeding a BMI of 35 kg/m² and for those patients who are 30 kg/m² or higher who have at least one obesity-related condition, such as diabetes. Unfortunately, postoperative complications commonly result from bariatric surgical procedures, including bleeding, embolism or thrombosis, wound complications, deep infections, pulmonary complications, and gastrointestinal obstruction; reoperation during the postoperative period is sometimes necessary to address these complications. Rates of reoperation or conversion surgery beyond the postoperative period depend on the type of bariatric procedure, and in one study ranged from 17% to 31%. Intestinal absorptive abnormalities, such as micronutrient deficiency and protein-calorie malnutrition, also are typically seen with bypass procedures, requiring lifelong nutrient supplementation. Major and serious adverse outcomes associated with bariatric surgery are common, observed in approximately 4 percent of procedures performed (including death in 0.3 to 2 percent of all patients receiving laparoscopic banding or bypass surgeries, respectively).

SUMMARY OF THE INVENTION

[0007] This disclosure generally relates to methods of treating an overweight or obese subject or patient that include non-daily administration of a pharmaceutically effective amount of a MetAP2-inhibitor, such as 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagilloid or pharmaceutically acceptable salts thereof, to a patient in need thereof, e.g., a human or a companion animal such as a cat or a dog. For example, a method for treating obesity or for reducing body weight in a patient in need thereof is provided, comprising administering to the patient, on a less than daily basis, a dose of a formulation comprising a therapeutically effective amount of a compound 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagilloid or pharmaceutically acceptable salts thereof. Such a method, upon a single initial administration of a dose or after administration of two doses, may provide the patient with a weight loss of about 0.3 to about 2 kg of the initial patient weight. Such a disclosed method may provide a well tolerated rate of weight loss of about 1 to about 1.5% of the initial patient weight per week.

[0008] Contemplated methods may include administering to the patient a single dose of a disclosed formulation about every other day, twice weekly, about once a week, about once every other week, and/or about once or twice a month.

[0009] A method for treating obesity or for reducing body weight in a patient in need thereof is provided wherein that includes administering to the patient a dose of a formulation comprising a therapeutically effective amount of a com-
compound 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillin or pharmaceutically acceptable salts thereof, for a first period of time, withheld for a second period of time, and again administered for a third period of time, wherein the therapeutically effective amount provides the patient with a body weight loss of, for example, about 1% to about 2% initial patient weight per week (and/or provides for a body weight loss of about 0.5 kg to about 2 kg or more) after the first period of time. A first period of time may be selected from the group consisting of daily, every other day, every three, four or five days, twice weekly, or monthly. A second period of time may be selected from the group consisting of one, two, three, four, five, or six days, one, two, three, four, or five weeks, and one month. A third period of time may be selected from daily, every other day, every three, four or five days, twice weekly, monthly, or every other month.

Contemplated doses may include therapeutically effective amount of the disclosed compound of e.g., about 0.5 mg/m² to about 3 mg/m² (based on a patient’s actual or calculated surface area), e.g. about 0.9 mg/m² to about 1.5 mg/m², e.g., about 1.25, 1.5, 2 or 3 mg/m². In other embodiments, a therapeutically effective amount of a disclosed compound may be at least about 20 to about 80 μg per kg, or at least about 20 to about 40 μg per kg excess body weight of the patient. For example, a therapeutically effective amount of a disclosed compound, e.g., administered every three or four days may be a dosage that includes e.g., about 1.8 mg, 2.5 mg, 2 mg, 3 mg, 4 mg, 5 mg, or 6 mg of a disclosed compound. Administration of a single dose with such a method may reduce weight in the patient for at least three or four days, or up to seven days, for example, even without further administration.

Disclosed methods may include maintaining from 0 to 0.3 ng/mL of the compound in the plasma of a patient for at least 12 hours to 24 hours or more after administration of a dose, but for example, no longer than about 36 hours after administration. It may be understood that disclosed methods may include repeatedly administering to the patient an effective dose on a less than daily basis until a desired weight is achieved.

For example, provided herein is a method for treating obesity or for reducing body weight in a patient in need thereof, comprising administering to the patient a dose comprising about 0.9 mg/m² or more (e.g., about 0.75 mg/m² to about 3 mg/m²), of a compound 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillin or pharmaceutically acceptable salts thereof, wherein, for example, a single administration of the dose reduces weight in the patient for at least three days or at least four days.

Disclosed methods may include administering about 20 μg to about 80 μg of the compound per excess body weight of the patient. For example, a method for treating obesity or for reducing body weight is provided that comprises administering to a patient in need thereof at least about 30 μg or at least about 40 μg (e.g., at least about 40 μg to about 60 μg) of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillin or pharmaceutically acceptable salts thereof per kg of excess adipose tissue of the patient. In an embodiment, a method of reducing the body weight of a patient in need thereof for at least four days is provided comprising administering to the patient a single dose of at least about 20 μg of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillin or pharmaceutically acceptable salts thereof, per kg of excess adipose tissue of the patient. Such a method may further comprises administering a second dose (e.g., at intervals of two, three or four days or more) of at least about 40 μg of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillin or pharmaceutically acceptable salts thereof, per kg of excess body weight of the patient at least about 2 days after administration of the single dose. A disclosed method may further comprise administering subsequent doses at intervals of between about 4 days and 1 month, and/or may comprise maintaining about 0 to about 0.3 ng/mL of the compound in the plasma of a patient for 24 hours after administration, e.g., for about 24 to about 36 hours after administration.

[0014] A method for treating obesity or for reducing body weight in a patient in need thereof is also provided comprising administering to the patient, on a less than daily basis, a dose of a formulation comprising a therapeutically effective amount of a compound 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillin or pharmaceutically acceptable salts thereof, wherein the method produces less testes-related toxicity as compared to a patient administered the dose on a daily basis.

[0015] In some embodiments, a disclosed method may provide, upon administration, adiponectin levels in the patient that are increased by at least 50% above the adiponectin level in the patient before administration. Contemplated human patients may have an initial body mass index of at least about 27 kg/m², at least about 30 kg/m², or at least about 35, or at least about 40 kg/m². Administering as contemplated herein may comprise subcutaneous administration or intravenous administration.

[0016] For example, provided herein is a method for treating obesity in a patient having an initial body mass index of at least about 30 kg/m², comprising administering to the patient (e.g., human), on a less than daily basis (e.g., twice weekly, weekly, or every 3 or 4 days) a dose of a formulation comprising a therapeutically effective amount of a compound 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillin or pharmaceutically acceptable salts thereof, as well as a method for reducing the weight of a patient (e.g., human) having an initial body mass index of at least about 27 kg/m², and suffering from weight related co-morbidity (e.g., hypertension, type 2 diabetes, dyslipidemia, and/or central adiposity), comprising administering to the patient, on a less than daily basis e.g., twice weekly, weekly, or every 3 or 4 days, a dose of a formulation comprising a therapeutically effective amount of a compound 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillin or pharmaceutically acceptable salts thereof. The dose comprises about 0.5 mg/m² to about 1.5 mg/m² of the compound, or about 30 μg to about 90 μg of the compound per kilogram of excess body weight of the patient, about 20 μg to 60 μg about per kilogram of ideal body weight of the patient, or 1.5 to about 6.0 mg of the free base of the compound.

[0017] Also provided herein is a pharmaceutically acceptable formulation comprising a compound 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillin or pharmaceutically acceptable salts thereof, wherein a single dose parenteral administration of the formulation to a human patient produces a peak plasma concentration (C_{max}) of about 0.5 to about 14 ng/mL or a peak plasma concentration may be about 0.5 to about 6 ng/mL. In some embodiments, the minimum plasma concentration (C_{min}) 24 hours after the administration is about 0 to about 0.3 ng/mL. In an embodiment, the
minimum plasma concentration in a patient 36 hours after administration is de minimus, or not detectable, e.g. about 0 ng/mL.

[0018] A pharmaceutically acceptable formulation is contemplated that includes a compound 6-O-(4-dimethylaminooethoxy)cinnamoyl fumarigillo or pharmaceutically acceptable salts thereof; wherein a single dose parenteral (e.g. intravenous or subcutaneous) administration of the formulation to a human patient produces a minimum plasma concentration (C_{min}) 24 hours after administration of about 0 to about 0.3 ng/mL. Such single dose administration to a human may produce a mean area under the curve concentration of the compound of (AUC (0-24 hours)) of about 6 to about 30 ng hr/mL, or about 8.6 to about 13.9 ng hr/mL.

BRIEF DESCRIPTION OF FIGURES

[0019] FIG. 1 depicts body weight change (percent) with twice weekly dosing of 0.1 mg/m², 0.3 mg/m², and 0.9 mg/m² (approximately 1.8 to 2.1 mg) of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumarigillo in human patients. Values are means±SEM (n=6 per dose level study); p values derived from 2-way ANOVA with Bonferroni post-test comparisons (*, p<0.05; ***, p<0.001 vs. placebo).

[0020] FIG. 2 depicts visual analogue scale of hunger decline by approximately 50% with body weight change (percent) with twice weekly dosing of 0.1 mg/m², 0.3 mg/m², and 0.9 mg/m² (approximately 1.8 to 2.1 mg) of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumarigillo in human patients. Values are means (n=6 per dose level) of changes in fasted Visual Analogue Scale scores for each visit day vs. Day 1 for population; p values derived from 2-way ANOVA with Bonferroni post-test comparisons (*, p<0.05; ***, p<0.001 vs. placebo).

[0021] FIG. 3 depicts dose exposure stability. Y-axis is plasma concentration of compound in ng/mL trials of participants receiving 0.9 mg/m².

[0022] FIG. 4 shows average pharmacokinetic (PK) profile with dose (ng/mL) of drug at day 26 of trials participants receiving 0.1, 0.3 and 0.9 mg/m².

[0023] FIG. 5 depicts correlation of weight change and exposure of drug at 24 hours.

[0024] FIG. 6 depicts the body weight change (kg) as a function of a μg per kg excess weight dose of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumarigillo in obese human patients. X axis is dose of compound (μg/kg of excessive weight).

[0025] FIG. 7 depicts weight change in patients administered a twice a week dose of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumarigillo, with varied dosages amounts. Weight loss plateaus at 0.9 mg/m² (~1.8 mg dose) administered twice weekly, with a maximum efficacy obtained with a dose administered biweekly of ~20 μg/kg.

[0026] FIG. 8 depicts the correlation between adiponectin changes and excess weight loss after administration of the disclosed MetAP-2 inhibitor in human obese patients.

[0027] FIG. 9 depicts the effect of administration of the disclosed MetAP-2 inhibitor on the ratio of leptin to adiponectin serum levels in human obese patients after administration.

[0028] FIG. 10 depicts the seminal vesicle weight and testes weight in rats after daily or every three days indicating a less than daily dosing safety window.

DETAILED DESCRIPTION

Overview

[0029] The disclosure in part relates to treatment of e.g., obesity using less than daily dosing and arises in part due to the unexpected discovery that the effectiveness of the drug remains for several days after administration of an initial dose, even though the half life of the drug is shorter than one day, together with the additional unexpected discovery that dosing and/or effectiveness of the drug depends on the amount of excess body weight of an overweight patient, rather than total body weight of the patient.

[0030] Obesity and being overweight refer to an excess of fat in proportion to lean body mass. Excess fat accumulation is associated with increase in size (hypertrophy) as well as number (hyperplasia) of adipose tissue cells. Obesity is variously measured in terms of absolute weight, weight: height ratio, degree of excess body fat, distribution of subcutaneous fat, and societal and esthetic norms. A common measure of body fat is Body Mass Index (BMI). The BMI refers to the ratio of body weight (expressed in kilograms) to the square of height (expressed in meters). Body mass index may be accurately calculated using the formulas: SI units: BMI=weight (kg)/height² (m²), or US units: BMI= (weight (lb)*703)/height² (in²).

[0031] In accordance with the U.S. Centers for Disease Control and Prevention (CDC), an overweight adult has a BMI of 25 kg/m² to 29.9 kg/m², and an obese adult has a BMI of 30 kg/m² or greater. A BMI of 40 kg/m² or greater is indicative of morbid obesity or extreme obesity. For children, the definitions of overweight and obese take into account age, stature, and gender as they relate to what are appropriate amounts of body fat and do not strictly rely upon BMI calculations.

[0032] BMI does not account for the fact that excess adipose can occur selectively in different parts of the body, and development of adipose tissue can be more dangerous to health in some parts of the body rather than in other parts of the body. For example, “central obesity”, typically associated with an “apple-shaped” body, results from excess adiposity especially in the abdominal region, including belly fat, and intra-abdominal, or visceral fat, and carries higher risk of co-morbidity than “peripheral obesity”, which is typically associated with a “pear-shaped” body resulting from excess adiposity especially on the hips. Measurement of waist/hip circumference ratio (WHR) can be used as an indicator of central obesity. A minimum WHR indicative of central obesity has been variously set, and a centrally obese adult typically has a WHR of about 0.85 or greater if female and about 0.9 or greater if male. Methods of determining whether a subject is overweight or obese that account for the ratio of excess adipose tissue to lean body mass may involve obtaining a body composition of the subject. Body composition can be obtained by measuring the thickness of subcutaneous fat in multiple places on the body, such as the abdominal area, the subscapular region, arms, buttocks and thighs. These measurements are then used to estimate total body fat with a margin of error of approximately four percentage points. Another method is biodiagnosis for body composition. Increased body fat will result in greater buoyancy, while greater muscle mass will result in a tendency to sink. Yet
another method is fan-beam dual energy X-ray absorptiometry (DEXA). DEXA allows body composition, particularly total body fat and/or regional fat mass, to be determined non-invasively.

[0033] Excess body weight may be assessed, for example, by comparing the weight of a patient in need of treatment to the weight of the same patient that would achieve a desired, e.g., non-obese BMI (e.g., a desired BMI of about 25 or less). For example, excess body weight of a 1.6 m patient weighing 89.6 kg (and having a BMI of 35) may be found by calculating the weight required for a BMI of 25 (i.e., about 64 kg); the initial excess body weight of such patient would about 89.6–64–25.6 kg. Ideal body weight can be assessed, for example, by calculating 25*(height of patient), or e.g., by consulting Metropolitan or other life insurance tables.

Methods

[0034] A method for treating obesity or for reducing body weight in a patient in need thereof is provided herein, comprising administering to the patient, on a less than daily basis, a dose of a formulation comprising a therapeutically effective amount of a compound 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillol or pharmaceutically acceptable salts thereof. Such methods may include administering to the patient a single dose of the formulation about every other day (e.g., every 2 days); twice weekly (e.g., every 4 days, every 5 days, every 6 days, or e.g., administered with an interval of about 2 to about 3 days between doses), once a week, every other week, twice monthly, once a month or even less often. In some embodiments, contemplative methods include administering a single dose no more than twice weekly, e.g. no more than every other day or e.g., every third day. It may be appreciated that methods that include administering a single dose on a less frequent basis, may, in some embodiments, be a method directed to maintaining a specific weight, such as a more optimal body weight after treatment using other methods disclosed herein. Disclosed methods may include administering a dose of a disclosed compound on a less than daily basis until a desired weight is achieved.

[0035] In another embodiment, provided herein is a method for treating obesity or for reducing body weight in a patient in need thereof, comprising administering to the patient a dose of a formulation comprising a therapeutically effective amount of a compound 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillol or pharmaceutically acceptable salts thereof; for a first period of time, withheld for a second period of time, and again optionally administered for a third period of time, e.g., alternate dosing regimens. For example, for the first period of time a patient may be administered a disclosed formulation daily, every other day, every three, four or five days, twice weekly, weekly, twice monthly, monthly, or yearly; during the second period of time (e.g., 1 day, 1 week, 2 weeks, 1 month) no dose is administered; and during e.g. a third period of time, the patient may be administered on a regimen similar or different to the first period of time, for example, every other day, every three, four or five days, biweekly, monthly, or yearly. At each administration or period time, the route of administration may be different or the same as another period of time.

[0036] A method for treating obesity or for reducing body weight in a patient in need thereof is also provided comprising administering to the patient, on a less than daily basis, a dose of a formulation comprising a therapeutically effective amount of a compound 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillol or pharmaceutically acceptable salts thereof, wherein the method produces less testes-related toxicity as compared to a patient administered the dose on a daily basis. For example, disclosed methods of administering a single dose of a disclosed compound on a less than daily basis may have no (or minimal) testicular tissue (e.g., seminal vesicle or testes) weight effects, while daily administration (of e.g., the same single dose) may result in testicular lesions and/or organ weight effects.

[0037] For example, provided herein, in an embodiment, is a method for treating obesity in a patient having an initial body mass index of at least about 30 kg/m², comprising administering a dose of the disclosed compound, on a less than daily basis (e.g., every three or four days, or twice weekly) to the patient. In another embodiment, provided herein is a method for reducing the weight of a patient having an initial body mass index of about 27 kg/m² and a co-morbidity, comprising administering a dose of the disclosed compound, on a less than daily basis (e.g., every three or four days, or twice weekly) to the patient. Such methods may provide for weight loss by the patient of about 1 kg to 1.5 kg per week. Contemplated doses, administered on a less than daily basis, may be a fixed dose, for example, about 1 mg, 2 mg, 1.5 mg, 1.8 mg, 2.5 mg, 3.0 mg, 4 mg, 5 mg or even 6 mg.

[0038] The therapeutically effective amount administered in the disclosed methods such as those above may provide a patient with a body weight loss of about 0.3% to about 2%, about 0.4% to about 2%, or about 0.5% to about 2% or more, or about 0.5 kg to about 2 kg or more of the initial patient weight even after an initial dose, or after administration of two doses, or after administering after an first period of time, e.g., such methods may incur weight loss for three or four days or more after administration (e.g. parenteral (for example intravenous) administration) of a single dose. For example, a patient, after receiving a first dose and/or after receiving a subsequent dose, may continue to lose weight for three or four days or more without further administration of a disclosed compound. In some embodiments, administration of an initial first dose, or administration of a first and second dose (e.g., both administered in the same week), may provide about 0.5 kg to about 2 kg or more of weight loss. Subsequent administration may result in further weight loss, until a target patient weight is achieved.

[0039] Therapeutically effective doses may be calculated, for example, on the basis of body surface area (BSA), which can be determined using formulae such as those described by Mosteller (Mosteller R D, N Engl J Med 1987 Oct 22: 317(17):1098), in which BSA is calculated in SI units as BSA (m²)=((Height (cm)x Weight (kg))/3600)²/² (e.g., BSA=SQRT (cm²/kg³)) or US units, in which BSA (m²)=((Height in)²x Weight (lbs)/3131)³². In some embodiments, the therapeutically effective amount administered (e.g., intravenously) to patient using a disclosed method is about 0.5 mg/m² to about 1.5 mg/m², or about 0.9 mg/m² (or approximately 10 to 20 µg per kilo of total body weight) or more of a disclosed compound. In other embodiments, a therapeutically effective amount is based on excess body weight (or excess adipose tissue), for example, at least about 30 µg of a disclosed compound per kg of excess adipose tissue, (or excess body weight) of the patient, or less about 40 µg per kg or more of excess adipose tissue, or excess body weight) of the patient, e.g., about 30 µg per kg of
excess adipose tissue (or excess body weight) to about 60 µg per kg, about 40 µg per kg to about 60 µg per kg, or about 35 µg per kg to about 45 µg per kg, or about 35 µg per kg to about 50 µg per kg of excess adipose tissue (or excess body weight).

[0040] For example, provided herein is a method for treating obesity or for reducing body weight in a patient in need thereof, comprising administering to the patient a dose comprising about 0.9 mg/m² or more (about 0.75 mg/m² to about 3 mg/m², or about 0.9 mg/m² to about 1.5 mg/m²) of a compound 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillo or pharmaceutically acceptable salts thereof, wherein a single administration of the dose reduces weight in the patient for at least four days.

[0041] In another embodiment, a method of treating obesity in a patient in need thereof is provided, comprising administering an effective amount of a MetAP2 inhibitor, wherein the effective amount is proportional to excess body weight of said patient. For example, in some embodiments, such effective amount may not be proportional to total body weight. A method of treating obesity in a patient in need thereof is also provided, comprising determining the excess body weight or excess adipose tissue of said patient; determining an effective dose of a MetAP2 based on the excess body weight or adipose tissue for said patient; and administering the effective dose to said patient.

[0042] For example, provided herein is a method for treating obesity or for reducing body weight, comprising administering to a patient in need thereof at least about 20 µg, 30 µg, or at least about 40 µg or more (e.g., about 20 µg to about 80 µg, or about 40 µg to about 60 µg) of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillo or pharmaceutically acceptable salts thereof per kg of excess adipose tissue (or excess body weight) or, in other embodiments, about 0.9 mg/m² (e.g., of calculated surface area), or more (e.g., about 0.75 mg/m² to about 3 mg/m²), of the patient.

[0043] In another embodiment, a method of treating obesity or for reducing body weight is provided comprising administering a dose, on a less than weekly basis, of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillo or pharmaceutically acceptable salts wherein the effective dose comprises at least about 35 µg to about 75 µg per kilogram, about 20 to about 60 µg/kg ideal body weight, or about 20 to about 40 µg/kg of the compound per ideal body weight of the patient, wherein ideal body weight is 25*(patient height in meters).

[0044] Disclosed methods may reduce the body weight of the patient for at least 3 or at least 4 days after administration, or at least 7 days after administration, at least 14 days after administration, or even at least 1 month after administration, e.g., without further administration of the compound during that time. It is understood that even though an administration may provide for weight loss e.g. at least for 3 or 4 days, a disclosed compound may be administered more frequently, e.g. every other day.

[0045] For example, provided herein is a method of reducing the body weight of a patient in need thereof for at least four days, comprising administering (e.g., parenterally administering) to the patient a single dose of at least about 40 µg of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillo or pharmaceutically acceptable salts thereof, per kg of excess adipose tissue of the patient. In some embodiments, such methods may further include administering a second dose of at least about 20 µg of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillo or pharmaceutically acceptable salts thereof, per kg of excess body weight of the patient (or, in other embodiments, about 0.9 mg/m² or more (or about 0.75 mg/m² to about 3 mg/m²) at least about 4 days after administration of the single dose. A second dose, for example, may be administered at intervals of three or four days or more. In another embodiments, disclosed methods may further include administering subsequent doses of a MetAP2 inhibitor (e.g., 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillo) at intervals of between about 4 days and 1 month. Such disclosed methods may, upon administration, increase the adiponectin levels of the patient by at least 50% above, or at least 20%, at least 30% at least 40%, or more, e.g. at least 20% to about 60% above the adiponectin level in the patient before administration (e.g. baseline adiponectin of the patient before treatment.)

[0046] In another aspect, a method of treating obesity in a patient in need thereof is provided comprising administering to a patient an effective amount of an MetAP2 inhibitor, wherein the effective amount is capable of increasing adiponectin levels in the patient by at least 50% above, at least 60% above, or at least 20%, at least 30% at least 40%, or more, e.g. at least 20% to about 60%, or the adiponectin level in the patient before administration of the inhibitor. Such an effective amount of the MetAP2 inhibitor may reduce the ratio of leptin to adiponectin plasma levels in the patient after administration. Further, therapeutically effective doses contemplated herein will not typically induce any clinically significant anti-angiogenic action.

[0047] Also provided herein is a method of optimizing weight loss in a patient undergoing weight loss treatment, comprising a) administering an amount of a MetAP2 inhibitor to said patient; b) determining the increase in adiponectin in said patient; and c) increasing the amount of the MetAP2 inhibitor administered to the patient if the change in adiponectin in the patient is less than an increase of about 60% or more (or 50% or more, e.g. 30% to about 60%) compared to the adiponectin level of the patient before administration of the MetAP2 inhibitor.

[0048] In another embodiment, a method of optimizing weight loss in a patient undergoing weight loss treatment, comprising a) administering an amount of a MetAP2 inhibitor to said patient; b) determining the increase in adiponectin in said patient; c) increasing the amount of the MetAP2 inhibitor administered to the patient if a reduction in the ratio of leptin to adiponectin in the plasma of the patient is not greater than 50%, or not greater than 40%, e.g., the reduction of the ratio of leptin to adiponectin is reduced by about 10%, 20%, 30% or 40%.

[0049] Contemplated patients include humans or companion animals (e.g. dog or cat). In some embodiments, patients may be female (e.g., in an embodiment, women of non-child bearing potential) or male (e.g., in an embodiment, surgically or biologically sterile males).

[0050] In addition to being overweight or obese, a patient may be suffering from other overweight- or obesity-related co-morbidities, i.e., diseases and other adverse health conditions associated with, exacerbated by, or precipitated by being overweight or obese. Because being overweight or obese is associated with other adverse health conditions or co-morbidities, for example diabetes, administering a disclosed MetAP2 inhibitor may bring a benefit in ameliorating, arresting development of or, in some cases, even elimi-
nating, these overweight- or obesity-related conditions or co-morbidities. For example, contemplated methods of reducing body weight disclosed herein includes treatment those patients who have e.g., a BMI of greater than 27 kg/m^2^, and who have one or more weight related co-morbidities, such as hypertension, type 2 diabetes, dyslipidemia, and/or central adiposity.

[0051] In some embodiments, methods provided herein may further include administering at least one other agent in addition to a disclosed MetAP2 inhibitor, e.g., an agent directed to treatment of these overweight- or obesity-related conditions.

[0052] Contemplated other agents include those administered to treat type 2 diabetes such as sulfonylureas (e.g., chlorpropamide, glipizide, glyburide, glimepiride); meglitinides (e.g., repaglinide and nateglinide); biguanides (e.g., metformin); thiazolidinediones (rosiglitazone, troglitazone, and pioglitazone); glucagon-like 1 peptide mimetics (e.g. exanetide and liraglutide); sodium-glucose cotransporter inhibitors (e.g., dapagliflozin), renin inhibitors, and alpha-glucosidase inhibitors (e.g., acarbose and miglitol), and/or those administered to treat cardiac disorders and conditions, such hypertension, dyslipidemia, ischemic heart disease, cardiomyopathy, cardiac infarction, stroke, venous thromboembolic disease and pulmonary hypertension, which have been linked to overweight or obesity, for example, chlorothalidone; hydrochlorothiazide; indapamide, metolazone; loop diuretics (e.g., bumetanide, ethacrynic acid, furosemide, lasix, torsemide); potassium-sparing agents (e.g., amiloride hydrochloride, spironolactone, and triamterene); peripheral agents (e.g., reserpine); central alpha-agonists (e.g., clonidine hydrochloride, guanabenz acetate, guanfacine hydrochloride, and methyldopa); alpha-blockers (e.g., doxazosin mesylate, prazosin hydrochloride, and tenoxazosin hydrochloride); beta-blockers (e.g., acebutolol, atenolol, betaxolol, nisoprolol fumarate, carteolol hydrochloride, metoprolol tartrate, metoprolol succinate, Nadolol, penbutolol sulfate, pindolol, propranolol hydrochloride, and timolol maleate); combined alpha- and beta-blockers (e.g., carvedilol and labetalol hydrochloride); direct vasodilators (e.g., hydralazine hydrochloride and minoxidil); calcium antagonists (e.g., diltiazem hydrochloride and verapamil hydrochloride); dihydropryridines (e.g., amlodipine besylate, felodipine, isradipine, nicardipine, nifedipine, and nisoldipine); ACE inhibitors (benazepril hydrochloride, captopril, enalapril maleate, fosinopril sodium, lisinopril, moexipril, quinapril hydrochloride, ramipril, trandolapril); angiotensin II receptor blockers (e.g., losartan potassium, valsartan, and Irbesartan); and combinations thereof, as well as statins such as mevastatin, lovastatin, pravastatin, simvastatin, velostatin, pravastatin, simvastatin, fenofibrate, fenofibric acid, and gemfibrozil, typically for treatment of dyslipidemia.

[0053] Other agents that may be co-administered (e.g. sequentially or simultaneously) include agents administered to treat ischemic heart disease including statins, nitrates (e.g., Isosorbide Dimiate and Isosorbide Mononitrate), beta-blockers, and calcium channel antagonists, agents administered to treat cardiomyopathy including inotropic agents (e.g., Digoxin), diuretics (e.g., Furosemide), ACE inhibitors, calcium antagonists, anti-arrhythmic agents (e.g., Sotolol, Amiodarone and Disopyramide), and beta-blockers, agents administered to treat cardiac infarction including ACE inhibitors, Angiotensin II receptor blockers, direct vasodilators, beta blockers, anti-arrhythmic agents and thrombolytic agents (e.g., Alteplase, Retaplace, Tenecteplase, Anistreplase, and Urokinase), agents administered to treat strokes including anti-platelet agents (e.g., Aspirin, Clopidogrel, Dipyridamole, and Ticlopidine), anticoagulant agents (e.g., Heparin), and thrombolytic agents, agents administered to treat venous thromboembolic disease including anti-platelet agents, anticoagulant agents, and thrombolytic agents, agents administered to treat pulmonary hypertension include inotropic agents, anticoagulant agents, diuretics, potassium (e.g., K-dur), vasodilators (e.g., Nifedipine and Diltiazem), Bosentan, Epoprostenol, and Silde- nafil, agents administered to treat asthma include bronchodilators, anti-inflammatory agents, leukotriene blockers, and anti-ige agents. Particular asthma agents include Zafirlukast, Flunisolide, Tamcimelone, Beclomethasone, Terbutaline, Fluticasone, Formoterol, Beconemheasone, Salmeterol, Theophylline, and Xopenex, agents administered to treat sleep apnea include Modafinil and anapetamines, agents administered to treat nonalcoholic fatty liver disease include antioxidants (e.g., Vitamins E and C), insulins sensitizers (Metformin, Pioglitazone, Rosiglitazone, and Betaine), hepatoprotectants, and lipid-lowering agents, agentsadministered to treat osteoarthritis of weight-bearing joints include Acetaminophen, non-steroidal anti-inflammatory agents (e.g., Ibuprofen, Etodolac, Ozaopen, Naproxen, Diclofenac, and Nabumetone), COX-2 inhibitors (e.g., Celecoxib), steroids, supplements (e.g. glucosamine and chondroitin sulfate), and artificial joint fluid, agents administered to treat Prader-Willi Syndrome include human growth hormone (HGH), somatropin, and weight loss agents (e.g., Orlistat, Sibutramine, Methamphetamine, Itonamin, Phenetermine, Bupropion, Diethylpropion, Phenmetrazine, Benzphetamine, and Topamax), agents administered to treat polycystic ovary syndrome include insulin-sensitizers, combinations of synthetic estrogen and progesterone, Spironolactone, Efflornithine, and Clomiphen, agents administered to treat erectile dysfunction include phosphodiesterase inhibitors (e.g., Tadalafil, Sildenafil citrate, and Vardenafil), prostaglandin E analogs (e.g., Alprostadil), alkaldoids (e.g., Yohimbine), and testosterone, agents administered to treat infertility include Clomiphene, Clomiphene citrate, Bromocriptine, Gonadotropin-releasing Hormone (GnRH), GnRH agonist, GnRH antagonist, Tamoxifen/nolvadex, gonadotropins, Human Chorionic Gonadotropin (HCG), Human Menopausal Gonadotropin (Human), progesterone, recombinant follicle stimulating hormone (FSH), Urofolitropin, Heparin, Folitropin alfa, and Folitropin beta, agents administered to treat obstetric complications include Bupivacaine hydrochloride, Dinoprost FGE2, Meperidine HCl, Ferro-folic-500/iberete-folic-500, Meperidine, Methylerygonovone maleate, Ropivacaine HCl, Nalbuphine HCl, Oxymorphine HCl, Oxytocin, Dinoprostone, Rito- drine, Scopolamine hydrobromide, Sufentanil citrate, and Oxytocic, agents administered to treat depression include seroton reuptake inhibitors (e.g., Fluoxetine, Escitalopram, Citalopram, Paroxetine, Sertraline, and Venlafaxine); tricyclic antidepressants (e.g., Amitriptyline, Amoxapine, Clomipramine, Desipramine, Doseule..
Nialamide, Iproniazid, Iproclozide, Toloxatone, Linezolid, Dienolide kavapyrone desmethoxyyangonin, and Dextroamphetamine; psychostimulants (e.g., Amphetamine, Methamphetamine, Methylphenidate, and Arecoline); antipsychotics (e.g., Butyrophenones, Phenothiazines, Thiokanthemones, Clozapine, Olanzapine, Risperidone, Quetiapine, Ziprasidone, Amisulpride, Paliperidone, Symbax, Tetrabenazine, and Cannabidiol); and mood stabilizers (e.g., Lithium carbonate, Valproic acid, Divalproex sodium, Sodium valproate, Lamotrigine, Carbamazepine, Gabapentin, Oxcarbazepine, and Topiramate), agents administered to treat anxiety include serotonin reuptake inhibitors, mood stabilizers, benzodiazepines (e.g., Alprazolam, Clonazepam, Diazepam, and Lorazepam), tricylic antidepressants, monoamine oxidase inhibitors, and beta-blockers, and other weight loss agents, including serotonin and noradrenergic re-uptake inhibitors; noradrenergic re-uptake inhibitors; selective serotonin re-uptake inhibitors; and intestinal lipase inhibitors. Particular weight loss agents include orlistat, sibutramine, methamphetamine, ionamin, phentermine, bupropion, diethylpropion, phendimetrazine, benzphetamine, and topiramate.

In some embodiments, contemplated methods may further comprise assessing one or more indices of on-going weight loss, e.g. the ketone body production level in a patient; and optionally adjusting the amount administered; thereby optimizing the therapeutic efficacy of said MetAP2 inhibitor.

Formulations

Contemplated administration of Met-AP2 inhibitors in the disclosed methods include subcutaneous or intravenous administration. For example, injectable preparations are contemplated herein, for example, sterile injectable aqueous or oleaginous suspensions may be formulated according to the known art using suitable dispersing or wetting agents and suspending agents.

Disclosed or contemplated treatment regimens can include a corrective phase, during which a MetAP2 inhibitor dose sufficient to provide reduction of excess adiposity is administered, followed by a maintenance phase, during which a lower or equivalent MetAP2 inhibitor dose sufficient to prevent re-development of excess adiposity may be administered.

In an embodiment, a pharmaceutically acceptable formulation is provided that includes a compound 6-O-(4-dimethylaminooxy)-cinnamoyl fumarigillo or pharmaceutically acceptable salts thereof; wherein a single dose administration of the formulation to a human patient produces a peak plasma concentration (C_max) of about 0.5 to about 14 ng/mL, about 0.5 to about 6 ng/mL, for example, the peak plasma concentration is about 2.1 ng/mL. Further, provided here is a pharmaceutically acceptable formulation is provided that includes a compound 6-O-(4-dimethylaminooxy)-cinnamoyl fumarigillo or pharmaceutically acceptable salts thereof; wherein a single dose administration of the formulation to a human patient produces a peak plasma concentration (C_max) of about 24 hours after administration of about 0.5 to about 0.7, about 0.0 to about 0.15 ng/mL, or about 0.03 to about 0.11 ng/mL, for example, about 0.07 ng/mL, for about 36 hours or less. For example, at 36 hours after a dosage administration, the plasma concentration in a patient is about 0, or undetectable using standard detection protocols as appreciated by those skilled in the art.

For example, provided herein is a pharmaceutically acceptable formulation that includes 6-O-(4-dimethylaminooxy)-cinnamoyl fumarigillo or pharmaceutically acceptable salts wherein the single dose administration (e.g. by subcutaneous or intravenous routes) to a human produces a mean area under the curve concentration of the compound of (AUC (0-24 hours)) of about 6 ng/hr/mL, to about 12 ng/hr/mL, 7.5 ng/hr/mL, to about 13.5 ng/hr/mL, or about 6 ng/hr/mL to about 15 ng/hr/mL, e.g. about 10.5 hr*ng/mL. In an embodiment, the mean area under the curve concentration of the compound (AUC (0-24)) after administration in a patient is about 6 ng/hr/mL, to about 16 ng/hr/mL, 7.6 ng/hr/mL, to about 4.4 ng/hr/mL, or about 9.3 ng/hr/mL, to about 12.7 ng/hr/mL, e.g. about 11 ng/hr/mL.

Examples

The examples which follow are intended in no way to limit the scope of this invention but are provided to illustrate aspects of the disclosed methods. Many other embodiments of this invention will be apparent to one skilled in the art. Unless specified, amounts or weights of the compound refer to the weight of the free base.

Example 1: Less than Weekly Administration of a MetAP2 Inhibitor to Obese Humans

Obese patients were treated in three cohorts with intravenous administration of a formulation of the compound 6-O-(4-dimethylaminooxy)-cinnamoyl fumarigillo oxide. The compound was intravenously administered to each patient of a cohort (except for a placebo cohort) twice weekly for 26 days. Each of patients in the three non-placebo cohorts received either 0.1 mg/m² (cohort 1); 0.3 mg/m² (cohort 2); or 0.9 mg/m² (cohort 3) doses of the compound at the time of administration. The trial was conducted under the appropriate government and medical supervision.

Weight reduction occurred for 4 days after single administration of 0.9 mg/m² dose, despite terminal half life of the drug of only 5.4 hours (T½(1) h) in the terminal 5.4±2.82 in cohort 3), indicating daily administration is not needed. Table 1 summarizes body weight determination of the 9 patients in the 0.9 mg/m² cohort on the day of the first dose and prior to a second dose administered three or four days later.

Of the 9 subjects treated at the 0.9 mg/m² dose level, 7 patients showed greater than 3.4 percent body weight loss over 26 days of exposure. FIG. 1 depicts the
body weight change (loss) as a percent before each administration of the twice weekly dose for the 0.9 mg/m² cohort. FIG. 2 depicts the Visual Analog Scale reports of hunger decline about 50% following successive biweekly dose administration for the 0.9 mg/m² cohort. As shown in FIGS. 1 and 2, a follow up check at day 36 was conducted; patients were weighed again at this 36 day mark and the weight loss from the twice weekly regimen over 26 days was substantially sustained.

The average Cmax in cohort 3 was 2.1 ng/mL (with a standard deviation of 0.51 ng/mL); average Cmax was 0.07 ng/mL (SD of 0.04 ng/mL, with a measured range of 0.014-0.15 ng/mL (including poor responder), and 0.045 to 0.15 (excluding poor responder)); average AUC (0-24 hr) was 10.5 hour*ng/mL (standard deviation 1.5 hour*ng/mL, measured range 8.57 to 13.6 hr*ng/mL) and average AUC (0-∞) was 11 hour*ng/mL (SD 1.7 hour*ng/mL). FIG. 3 depicts exposure of drug as function of dose with measurements taken at 5 min and 60 min post dose on each of several days of twice-weekly administration over a 26 day period, and shows that drug exposure stabilizes by the third or fourth dose administered.

There was a significant correlation between weight loss of patients and maintained exposure of 0.02 ng/mL of the drug above the level of quantification of the assay 24 hours after dosing, as shown in FIG. 4 (circled data point is exposure of one poor responder below the level of quantification of assay). The PK profile at day 26 is representative of steady state (see FIG. 5). Lack of efficacy at 0.1 and 0.3 mg/m² supports maintaining drug exposure above 0.02 ng/mL at 24 hours post dose, but with no drug exposure 36 hours after dosing.

Example 2 Correlation of Effective Dose and Excess Body Weight

All of the subjects of the trial described in Example 1 received doses ranging from 1.8 to 2.2 mg with each administration (given twice weekly). However, weight change was not strictly associated with dose delivered. Instead, response was strongly associated with dose administered per unit excess body weight, as compared to weight change associated with dose delivered per unit body weight. FIG. 6 indicates the body weight change of patients in the combined 0.1 and 0.3 mg/m² cohorts vs. dose of compound in µg per kg excess weight of patient, and indicates that exceeding approximately 40 µg of drug per kg of excess body weight may be important in order to see effects in obese patients.

This correlation may be due to obtaining the drug effect at least in part by exposure of the drug to adipose tissue. This indicates that dosing appropriately with a MetAP2 inhibitor surprisingly requires consideration of a patient’s excess weight (instead of total weight), given that drug exposures (drug amount) were not substantially different between subjects and both the vasculature and liver were dosed equivalently, but weight loss differed.

FIG. 7 indicates that weight loss efficacy is obtained at doses of ~20 µg/kg, and above, administered twice weekly.

Example 3 Adiponectin Levels

Levels of adiponectin in the serum of patients undergoing the trial were also measured. Adiponectin concentrations were markedly increased (by over 60%, see FIG. 8) with treatment, also pointing to the importance of adipose as a target for the drug since adiponectin is produced by fat cells. FIG. 8 also indicates that there is a strong correlation between adiponectin changes and excess weight loss.

Example 4 Toxicity Studies

A testis toxicity study was performed using daily subcutaneous administration or every other day (every third day) subcutaneous administration in rats. 1 mg/kg of 6-O-(4-dimethylaminophenoxycinnamoyl) fumagillo lactate (Compound) was administered daily and compared to every third day with the same dose. Additionally, equivalent total exposure using a 3 mg/kg dose administered every third day was compared as well.

64 Sprague-Dawley male rats within ±20% of mean body weight at initiation of dosing were used for the study. Vehicle control or Compound was administered once daily or every 3rd day for 4 weeks, at a volume of 5 mL/kg, as follows, with groups 1-4 for toxicity and groups 5-8 for toxicokinetic studies.

Upon completion of the study, complete necropsy examinations are performed, and the seminal vesicle, testes, and other organs are weighed at necropsy or as terminal weights. Terminal body weights are determined just prior to necropsy for assessment of organ weight changes.

Organ weight changes are shown in Table 2 and FIG. 10.

TABLE 2
As FIG. 10 shows, no tissue weight effects (testes and seminal vesicle weights) are observed in animals administered with less frequent dosing, indicating minimal or no testicular toxicity.

Table 3 shows the surprising findings from the study comparing 1 mg/kg/day dose with 1 mg/kg and 3 mg/kg every three days. While the 1 mg/kg/day dose indicates adverse findings (e.g., blood dyscrasias and/or irreversible testis lesions); the 3 mg/kg every three days does not show any significant adverse findings while reduces animal weight significantly, and increases the therapeutic window over prior findings using daily administration. The injection site tolerability appears to be acceptable even at doses up to 6 mg.

**EQUIVALENTS**

[0077] Various modifications of the invention and many further embodiments thereof, in addition to those shown and described herein, will become apparent to those skilled in the art from the full contents of this document, including references to the scientific and patent literature cited herein. The subject matter herein contains important information, exemplification and guidance that can be adapted to the practice of this invention in its various embodiments and equivalents thereof.
co-morbidity, and in need thereof, comprising parenterally administering once weekly to said patient about 1.8 mg of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillo or pharmaceutically acceptable salts thereof.

65. The method of claim 64, wherein parenterally administering is subcutaneously administering.

66. The method of claim 64, wherein parenterally administering is intravenously administering.

67. The method of claim 64, wherein administering to the patient once weekly is repeated until a desired weight is achieved.

68. A method for treating obesity in a human patient having an initial body mass index at least about 30 kg/m², or at least about 27 kg/m² and suffering from weight related co-morbidity, and in need thereof, comprising parenterally administering once weekly to said patient about 2.5 mg of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillo or pharmaceutically acceptable salts thereof.

69. The method of claim 68, wherein parenterally administering is subcutaneously administering.

70. The method of claim 68, wherein parenterally administering is intravenously administering.

71. The method of claim 68, wherein administering to the patient once weekly is repeated until a desired weight is achieved.

72. A method for treating obesity in a human patient having an initial body mass index at least about 30 kg/m², or at least about 27 kg/m² and suffering from weight related co-morbidity, and in need thereof, comprising parenterally administering once weekly to said patient about 3.0 mg of 6-O-(4-dimethylaminoethoxy)cinnamoyl fumagillo or pharmaceutically acceptable salts thereof.

73. The method of claim 72, wherein parenterally administering is subcutaneously administering.

74. The method of claim 72, wherein parenterally administering is intravenously administering.

75. The method of claim 72, wherein administering to the patient once weekly is repeated until a desired weight is achieved.
