(54) **Method and apparatus for communication between a vehicle based computing system and a remote application**

(57) A vehicle-based computing apparatus includes a computer processor in communication with persistent and non-persistent memory. The apparatus also includes a local wireless transceiver in communication with the computer processor and configured to communicate wirelessly with a wireless device located at the vehicle. The processor is operable to receive, through the wireless transceiver, a connection request sent from a no-

madic wireless device, the connection request including at least a name of an application seeking to communicate with the processor. The processor is further operable to receive at least one secondary communication from the nomadic device, once the connection request has been processed. The secondary communication is at least one of a speak alert command, a display text command, a create phrase command, and a prompt and listen command.

Fig-1

Description

[0001] The invention relates to a method and apparatus for communication between a vehicle based computing system and a remote application.

[0002] Vehicle based computing systems, such as the FORD SYNC system are growing in popularity. Using various sources of vehicle information, driver inputs and connections to vehicle systems, the SYNC system can add a variety of functionality and novelty to the driving experience.

[0003] Furthermore, systems such as SYNC can often communicate with remote devices either to gain information from those devices, or to use those devices to access a remote network. For example, in one instance, SYNC can communicate with a cellular phone, and use the cellular phone's ability to communicate with a remote network to send and receive information to and from the remote network. In another example, SYNC can query a GPS navigational device, such as a TOMTOM, and receive navigational information.

[0004] In addition to querying a device, such as a TOMTOM to receive navigational information, SYNC can also communicate with the TOMTOM and provide instructions, often comparable to pressing a selection on the TOMTOM's screen, through the SYNC system. The instructions can be provided, for example, by a spoken driver command processed through the SYNC system.

[0005] It is an object of the present invention to further improve the prior art of communication between a vehicle based computing system and a remote application.

[0006] For this purpose, the invention provides a vehicle based computing system and a remote application in accordance with claim 1.

[0007] In a first illustrative implementation, a vehicle-based computing apparatus includes a computer processor in communication with persistent and non-persistent memory. The apparatus also includes a local wireless transceiver in communication with the computer processor and configured to communicate wirelessly with a wireless device located at the vehicle.

[0008] In this illustrative embodiment, the processor is operable to receive, through the wireless transceiver, a connection request sent from the wireless device, the connection request including at least an identifier of an application seeking to communicate with the processor.

[0009] The processor is further operable to receive at least one secondary communication from the wireless device, once the connection request has been processed.

[0010] In another illustrative embodiment, a wireless device includes a processor in communication with at least persistent and non-persistent memory and a wireless transceiver operable to communicate with a vehicle-based computing system.

[0011] In this illustrative embodiment, the persistent memory stores instructions, possibly as part of an application, that, when executed by the processor, are oper-

able to cause communication between the wireless device and the vehicle-based computing system.

[0012] According to this illustrative implementation, the stored instructions, when executed by the processor, cause an initial connection request to establish a connection between an application stored on the wireless apparatus and the vehicle-based computing system.

[0013] The stored instructions further, when executed by the processor, cause at least one secondary communication to be sent to the processor, the communication pertaining to the operation of the application.

[0014] In yet another illustrative embodiment, a method of communication between an application stored on a wireless device and a vehicle-based computing system includes receiving, at the vehicle-based computing system, a request initiated by the application to connect the application to the vehicle-based computing system.

[0015] The illustrative method further includes establishing communication between the vehicle-based computing system, and the application on the wireless device. The exemplary method also includes receiving, at the vehicle-based computing system, at least a second communication pertaining to the operation of the application.

[0016] The present invention is described herein with reference to the drawings in the context of particular exemplary illustrative embodiments. However, it will be recognized by those of ordinary skill that modification, extensions and changes to the disclosed exemplary illustrative embodiments may be made without departing from the true scope and spirit of the instant invention. In short, the following descriptions are provided by way of example only, and the present invention is not limited to the particular illustrative embodiments disclosed herein.

FIG. 1 shows an illustrative exemplary vehicle based computing system and illustrative interaction of the system with an illustrative remote network;

FIG. 2 shows an illustrative exemplary remote device running one or more applications in communication with a vehicle based computing system; and

FIGS 3A-3F show exemplary process flows for exemplary illustrative commands sent from a device to a vehicle-based computing system.

[0017] These figures are not exclusive representations of the systems and processes that may be implemented to carry out the inventions recited in the appended claims.

[0018] Those of skill in the art will recognize that the illustrated system and process embodiments may be modified or otherwise adapted to meet a claimed implementation of the present invention, or equivalents thereof.

[0019] Figure 1 illustrates an example block topology for a vehicle based computing system 1 for a vehicle 31. A vehicle enabled with a vehicle-based computing system may contain a visual front end interface 4 located in

the vehicle. The user may also be able to interact with the interface if it is provided, for example, with a touch sensitive screen. In another illustrative embodiment, the interaction occurs through, button presses, audible speech and speech synthesis.

[0020] In the illustrative embodiment 1 shown in FIG. 1, a processor 3 controls at least some portion of the operation of the vehicle-based computing system. Provided within the vehicle, the processor allows onboard processing of commands and routines. Further, the processor is connected to both non-persistent 5 and persistent storage 7. In this illustrative embodiment, the non-persistent storage is random access memory (RAM) and the persistent storage is a hard disk drive (HDD) or flash memory.

The processor is also provided with a number of different inputs allowing the user to interface with the processor. In this illustrative embodiment, a microphone 29, an auxiliary input 25 (for input 33), a USB input 23, a GPS input 24 and a BLUETOOTH input 15 are all provided. An input selector 51 is also provided, to allow a user to swap between various inputs. Input to both the microphone and the auxiliary connector is converted from analog to digital by a converter 27 before being passed to the processor.

[0021] Outputs to the system can include, but are not limited to, a visual display 4 and a speaker 13 or stereo system output. The speaker is connected to an amplifier 11 and receives its signal from the processor 3 through a digital-to-analog converter 9. Output can also be made to a remote BLUETOOTH device such as PND 54 or a USB device such as vehicle navigation device 60 along the bi-directional data streams shown at 19 and 21 respectively.

[0022] In one illustrative embodiment, the system 1 uses the BLUETOOTH transceiver 15 to communicate 17 with a user's nomadic device 53 (e.g., cell phone, smart phone, PDA, etc.). The nomadic device can then be used to communicate 59 with a network 61 outside the vehicle 31 through, for example, communication 55 with a cellular tower 57.

[0023] Exemplary communication between the nomadic device and the BLUETOOTH Transceiver is represented by signal 14.

[0024] Pairing a nomadic device 53 and the BLUETOOTH transceiver 15 can be instructed through a button 52 or similar input, telling the CPU that the onboard BLUETOOTH transceiver will be paired with a BLUETOOTH transceiver in a nomadic device.

[0025] Data may be communicated between CPU 3 and network 61 utilizing, for example, a data-plan, data over voice, or DTMF tones associated with nomadic device 53. Alternatively, it may be desirable to include an onboard modem 63 in order to transfer data between CPU 3 and network 61 over the voice band. In one illustrative embodiment, the processor is provided with an operating system including an API to communicate with modem application software. The modem application software may access an embedded module or firmware

on the BLUETOOTH transceiver to complete wireless communication with a remote BLUETOOTH transceiver (such as that found in a nomadic device). In another embodiment, nomadic device 53 includes a modem for voice band or broadband data communication. In the data-over-voice embodiment, a technique known as frequency division multiplexing may be implemented when the owner of the nomadic device can talk over the device while data is being transferred. At other times, when the owner is not using the device, the data transfer can use the whole bandwidth (300 Hz to 3.4kHz in one example).

[0026] If the user has a data-plan associated with the nomadic device, it is possible that the data-plan allows for broad-band transmission and the system could use a much wider bandwidth (speeding up data transfer). In still another embodiment, nomadic device 53 is replaced with a cellular communication device (not shown) that is affixed to vehicle 31.

[0027] In one embodiment, incoming data can be passed through the nomadic device via a data-over-voice or data-plan, through the onboard BLUETOOTH transceiver and into the vehicle's internal processor 3. In the case of certain temporary data, for example, the data can be stored on the HDD or other storage media 7 until such time as the data is no longer needed.

[0028] Additional sources that may interface with the vehicle include a personal navigation device 54, having, for example, a USB connection 56 and/or an antenna 58; or a vehicle navigation device 60, having a USB 62 or other connection, an onboard GPS device 24, or remote navigation system (not shown) having connectivity to network 61.

[0029] Further, the CPU could be in communication with a variety of other auxiliary devices 65. These devices can be connected through a wireless 67 or wired 69 connection. Also, or alternatively, the CPU could be connected to a vehicle based wireless router 73, using for example a WiFi 71 transceiver. This could allow the CPU to connect to remote networks in range of the local router 73.

[0030] FIG. 2 shows an illustrative exemplary remote device running one or more applications in communication with a vehicle based computing system. In this illustrative embodiment, a remote device 209 (e.g., without limitation, a cell phone, PDA, GPS device, etc.) has one or more remote applications 201, 205 stored thereon. The remote applications communicate with the vehicle based computing system 247, using a vehicle computing system (VCS) client side API 203, 207. This API could, for example, be provided to developers in advance, and define the format of outgoing and incoming packets so that communication between the remote device 209 and the vehicle based computing system 247 is possible. A dispatcher 211 can be provided to the remote device 209 if more than one application is communicating at the same time.

[0031] Data is passed from the remote device to the vehicle communication system through a communication

link 213. This can be a wired or wireless link, and can be half or full duplex. In one non-limiting example, the link is a BLUETOOTH link.

[0032] The vehicle based communication system has various applications stored thereon, including, but not limited to: a communications manager 223, an API abstraction application 217, a management and arbitration application 219, and an adaptation application 221 (these applications can also be layers of a single or plurality of applications, such as a service provider application 215).

[0033] In this exemplary implementation, the communication manager 223 handles all transports, forwarding incoming messages to the abstraction application (or layer) 217, and ensuring that outgoing messages are sent via the proper transport channel.

[0034] In this exemplary implementation, the abstraction application 217 transforms incoming messages into action to be performed by a service and creates outgoing messages out of information and events from local modules.

[0035] In this exemplary implementation, the management and arbitration application 219 virtualizes the local vehicle based computing system for each application by managing use of HMI elements and governing resource consumption.

[0036] In this exemplary implementation, the adaptation application 221 encapsulates the local API and co-existence with core local applications. This application may be modified or replaced to allow a communication connection to compatible with different versions of the vehicle based computing system software.

[0037] In at least one exemplary implementation, a message protocol will be used to encode messages exchanged between a mobile client and the vehicle based computing system to command and control a Human Machine Interface (HMI) for purposes such as displaying and speaking text, listening, propagating button-pushes, etc. These messages may contain small amounts of data (e.g. text phrases, button identifiers, status, thumb-drive file data, configuration data, etc.). This protocol, using complementary support provided by the message specification, will permit multiple client application sessions to concurrently use a single transport channel.

[0038] Other open standard protocols may be used where appropriate and available, such as the A2DP BLUETOOTH profile for streaming audio from the mobile device to the vehicle audio system (not all mobile devices support A2DP). However, some open standard protocols are not always available on every mobile device, or are not always implemented uniformly. In addition, API support for use of these protocols may not be uniformly implemented on all mobile platforms. Therefore, the function of some open standard protocols (e.g. OBEX) may be provided as part of the message protocol, when it is technically simple enough to do and a significant increase in uniformity can be achieved across platforms.

[0039] Transports may be configured to support full-duplex communication in order to provide prompt event

propagation between client applications and the vehicle based computing system. A transport may also support multiple concurrent channels in order to permit concurrent connections from one or more devices.

[0040] One or more exemplary transports are Serial (RS232) and TCP/IP. Serial transport communication with mobile devices may provided, for example, through a BLUETOOTH Serial Profile. Most mobile devices support this profile, and most provide a common programming model for its use. The serial programming model is widely used and highly uniform. If the vehicle based computing system provides Serial-over-USB support, then the Serial transport could be used with any mobile device that is USB-connected to the vehicle based computing system (if that mobile device provides support for Serial over its USB connection).

[0041] In addition, a TCP/IP transport provides the ability for applications running on the vehicle based computing system to use the local HMI. If the module provides external TCP/IP connectivity in the future, this transport will allow external clients to connect over that TCP/IP connectivity. The socket programming model (including the API) for TCP/IP is typically highly portable. Such an example would be a locally loaded application 229, using a client-side API 227 to communicate through a local socket 225.

[0042] In at least one exemplary embodiment, the decoupled nature of the system, where the vehicle based computing system is unaware of client applications until they connect, demands a discovery mechanism whereby system and the mobile device client can discover each other's existence and capabilities.

[0043] Dual discovery is possible, whereby the mobile device client will be able to discover the environment, locale and HMI capabilities of the local platform and the system will be able to discover the applications available on a remote device and have the ability to launch those applications.

[0044] In this illustrative embodiment, the native API 231 has various services associated therewith, that can be accessed by remote devices through function calls. For example, a display function 233 may be provided.

[0045] The system may provide an API allowing client applications to write to vehicle displays and query their characteristics. The characteristics of each display may be described generically such that client applications will not require hard coding for individual display types (Type 1 FDM, Type 3 GAP, Type 6 Navigation, etc). Specifically, the system may enumerate each display and indicate each display's intended usage (primary or secondary display). Furthermore, the system may enumerate the writable text fields of each display, provide each writable text field's dimensions, and indicate each field's intended general usage. To promote consistency with the current user interface, support for the scrolling of long text may also be included, where permitted by driver distraction rules.

[0046] The system may also include text to speech ca-

pability 241. The system may provide an API allowing client applications to leverage the vehicle based computing system's text-to-speech functionality. Client applications may also be able to interleave the play of audio icons with spoken text. They may be able to utilize pre-existing audio icons or provide short audio files of their own. The format of application provided audio files will be limited to those natively supported.

[0047] Further functionality of the illustrative embodiments may include one or more button inputs 243. One example of this would be controlling an application on a remote device through use of buttons installed in a vehicle (such as steering wheel buttons).

[0048] Another exemplary function could be a speech recognition function 245. The system may provide an API allowing client applications to leverage the vehicle based computing system's speech recognition capabilities. The system may also simplify the vehicle based computing systems' native speech recognition APIs to provide a simpler development model for client application developers. The speech grammar APIs will also be simplified while retaining most of the native API's flexibility. For example, the system (on behalf of client applications) will recognize global voice commands such as "BLUETOOTH Audio" or "USB" and pass control to the appropriate application.

[0049] Audio I/O 237 may also be provided in an exemplary implementation. The system may provide regulated access to the HMI while enforcing the interface conventions that are coded into core applications. A single "in focus" client application may be allowed primary access to the display, buttons, audio capture or speech engine. Client applications without focus (e.g. Text Messaging, Turn By Turn Navigation, etc.) will be allowed to make short announcements (e.g. "New Message Arrived" or "Turn Left"). Stereo audio may continue to play after a mobile device audio application.

[0050] The system may provide an API allowing client applications to capture audio recorded using a microphone. The client application may specify duration of the capture, though capture can be interrupted at any time. Captured audio may be returned to the client application or stored on a local or portable drive.

[0051] Additionally, file I/O 235 may also be provided with the system. For example, the system may provide an API allowing client applications to read from, write to, create and/or delete files on a remote drive. Access to the remote drive file system may be restricted in that a client application may only read/edit data in a directory specific to that client application.

[0052] The system will provide an API allowing client applications to add, edit, and remove contacts to a phonebook. These contacts will later be used in voice commands or phonebook menu to dial a BLUETOOTH-connected phone. Contacts sent by client applications may be validated to ensure they do not violate constraints.

[0053] A similar interface may be provided to allow client applications to add/replace a ring tone that will sound

when the BLUETOOTH-connected phone has an incoming call. The ring tone audio will be checked to ensure it conforms to a preset maximum size and length and that its audio format is compatible with the system.

[0054] Finally, the system can provide various forms of security, to ensure both system integrity and driver safety. The system APIs may be limited to prevent inadvertent or malicious damage to the system and vehicle by a client application, including (but not limited to): Limited access to the vehicle CAN bus; limited access to a local file system; no or limited access to audio output volume; no access to disable PTT (push-to-talk), menu, or other buttons that a developer may deem essential; and no access to disable system voice commands or media player source commands.

[0055] Additionally, client applications connecting to SyncLink must be approved by the user. For example, the following criteria may be used: the user must install the client application on their mobile device; client applications connecting via BLUETOOTH must be running on a mobile device paired by the user to the vehicle based computing system module on which the system is running; and applications running locally on the module must be installed onto the module by the user.

[0056] The system may also use signed and privileged applications. For example, general applications may be signed with a VIN-specific certificate that allows them to interact only with specific vehicle(s). Certificates will be attached to the application install when the user obtains the application from the distribution model. Each certificate will contain an encrypted copy of a VIN-specific key and the application's identity. Upon connecting to the service, the application identity string and certificate are sent. The system decrypts the certificates, and verifies that the VIN key matches the module, and that the application identity matches that which is sent from the application. If both strings do not match, further messages from the application will not be honored. Multiple keys may be included with an application install to allow the application to be used with multiple vehicles.

[0057] In another illustrative example, privileged applications must run natively on the module itself. These applications must go through a standard code signing process required for all local applications. Applications that go through this process may not suffer from the same impersonation weakness experienced by general applications.

[0058] In yet another illustrative embodiment, one or more applications may publish data for receipt by one or more other applications. Correspondingly, one or more applications may subscribe to one or more data feeds published via the exemplary publish mechanism.

[0059] For example, a first application could be a music playing application, and publish data about a song being played by the application. The data can be sent to the system and provided with an ID that allows applications seeking to subscribe to the data to find the data. Alternatively, the vehicle computing system may recognize

that data is coming in for subscribers to that type of data, and broadcast that data to the subscribing entities.

[0060] A second application, a subscriber, could find and retrieve or be sent the data. The second application, in this example a social networking update program, could then use the data obtained through the subscription to the publication. In this example, the social networking application could update a website informing people as to what music was currently playing in the application user's car.

[0061] In addition to acting as a through-way for published data, the vehicle computing system itself could publish data for subscription. For example, GPS data linked to the vehicle computing system could be published by the vehicle computing system and subscribed to by applications desiring to use the data. These are just a few non-limiting examples of how publication/subscription can be used in conjunction with the illustrative embodiments.

[0062] An exemplary non-limiting set of API commands may include, but are not limited to:

ClientAppConnect(appName)

[0063] An example flow for this command is shown in FIG. 3A. This command may establish a connection to the vehicle based communication system 301 and provide the application's name 303. This operation may be asynchronous, and thus may need to wait for a response from the system 305. Completion may be indicated by receipt of an **OnConnectionStatusReceived** event which returns connection status and a unique connection ID 307. This connection ID is valid only for the duration of the connection.

[0064] **appName** - name which uniquely identifies this application on the mobile device. This name is unique on the mobile device, but may be used by another application connecting from another mobile device.

ClientAppDisconnect

[0065] This exemplary even may close the connection. Any further attempts by the client to use this connection will be ignored.

SpeakText(text, completionCorrelationID)

[0066] An exemplary flow for this command is shown in FIG. 3B. This command may cause the system to speak the specified text through the vehicle audio system by first acquiring priority for the audio system 311. Once priority is acquired 313, the command sends text 315 and waits for a response 317. Since this text is part of the normal application operation, priority may be required. This operation may be asynchronous and completion may be indicated by receipt of the **OnSpeakComplete** event 319 which returns a completion reason enumeration.

text - text to be spoken by SYNC

[0067] **completionCorrelationID** - identifier to be returned upon completion of speak operation (via **OnSpeakComplete** event).

SpeakAlert(text, completionCorrelationID)

[0068] An exemplary flow for this command is shown in FIG. 3C. This command may speak the specified text through the vehicle audio system. This command may send text 321 and wait for a response 323. In this instance, the API indicates that priority is not required when the command is sent, so that there is no need for priority because this is an alert. This operation is asynchronous and completion may be indicated by the **OnSpeakAlertComplete** event which returns a completion reason enumeration. This function is, for example, meant to be used by applications which do not currently have focus but which require brief one-way interaction (i.e. speak only, with no user input via voice or buttons possible) with the user.

text - text to be spoken by SYNC

[0069] **completionCorrelationID** - identifier to be returned upon completion of speak operation (via **OnSpeakAlertComplete** event).

DisplayText(text)

[0070] An exemplary flow for this command is shown in FIG. 3D. This command may cause the vehicle based computing system to display specified text on a console display. Priority may also be required. The command first seeks priority 331. Once priority is acquired 333, the text can be sent 335. In at least one embodiment, this should be a very short text string, as the display area may permit as few as twelve characters.

text - text to be displayed on the radio head by SYNC

CreateRecoPhraseSet(phraseList, thresholdIgnore, thresholdReject, completionCorrelationID)

[0071] An exemplary flow for this command is shown in FIG. 3E. This command may create a set of phrases that can be listened for during a PromptAndListen operation. The system may send a list of the possible phrases 341 and wait for a response 343 identifying a selected phrase (e.g., without limitation, the response sent by **PromptAndListen** shown in FIG. 3F). This operation may be asynchronous and completion may be indicated by a **OnRecoPhraseSetCreationComplete** event which returns a handle to this phrase set for use in subsequent calls to **PromptAndListen**.

[0072] **phraseSetList** - a list of strings (in .NET, a List<string>) that are to be recognizable.

[0073] **thresholdIgnore** - numeric value (percentage) between 0 and 100 indicating at what recognition confidence percentage must be attained for a phrase to NOT be ignored.

[0074] thresholdReject - numeric value (percentage) between 0 and 100 indicating at what recognition confidence percentage must be attained for a phrase to NOT be rejected.

[0075] completionCorrelationID - identifier to be returned upon completion of phrase-set creation operation (via **OnRecoPhraseSetCreationComplete** event).

PromptAndListen(initialPrompt, helpPrompt, rejectionPrompt, timeoutPrompt, recoPhraseSetHandleList, completionCorrelationID)

[0076] An exemplary flow for this command is shown in FIG. 3F. This command may prompt the user and listen for a recognized response. Priority may be required in this example, because an audio/visual prompt is being made. The system may first request priority 351. Once priority is acquired 353, the system then sends the packet of information 355 and waits for a response 357. Once a response is received, the system can then determine which response was given 359, based on, for example, an ID number. This operation may be asynchronous and completion may be indicated by a **OnPromptAndListenComplete** event which returns a completion reason and the recognized text.

[0077] recoPhraseSetHandleList - a list (in .NET, a List<>) of handles to one or more phrase sets that have already been created during this connection. A phrase that is recognized from any one of these phrase sets will be returned via the **OnPromptAndListenComplete** event.

[0078] initialPrompt - text to be spoken to user before listening starts.

[0079] helpPrompt - text to be spoken to user if they ask for help during listen.

[0080] rejectionPrompt - text to be spoken to user if they fail to speak a recognizable phrase

[0081] timeoutPrompt - text to be spoken to user if they fail to speak a recognizable phrase within a timeout period

[0082] completionCorrelationID - identifier to be returned upon completion of phrase-set creation operation (via **OnPromptAndListenComplete** event).

[0083] While the invention has been described in connection with what are presently considered to be the most practical and preferred embodiments, it is to be understood that the invention is not to be limited to the disclosed embodiments, but on the contrary, is intended to cover various modifications and equivalent arrangements included within the spirit and scope of the appended claims.

Claims

1. A vehicle-based computing apparatus comprising:

a computer processor in communication with persistent and non-persistent memory; and

a local wireless transceiver in communication with the computer processor and configured to communicate wirelessly with a wireless device located in proximity to vehicle;

wherein the processor is operable to receive, through the wireless transceiver, a connection request sent from a wireless device, the connection request including at least an identifier identifying an application configured to communicate with the processor and to provide services to a vehicle occupant; and

wherein the processor is further operable to receive at least one secondary communication from the wireless device pertaining to operation of the application, once the connection request has been processed.

2. The vehicle-based computing apparatus of claim 1, wherein the secondary communication is at least one of a speak alert command, a display text command, a create phrase command, and a prompt and listen command.

3. The vehicle-based computing apparatus of claim 2, wherein the speak alert command further includes a string of text to be spoken through a vehicle audio system, and wherein, if a speak alert command is received by the processor, the processor is further operable to instruct the vehicle audio system to immediately suppress any presently playing audio and speak the text.

4. The vehicle-based computing apparatus of claim 2 or 3, wherein the display text command further includes a string of text to be displayed on a vehicle display, and wherein, if a display text command is received by the processor, the processor is further operable to instruct the vehicle display to display the received text.

5. The vehicle-based computing apparatus of claim 4, wherein the vehicle display is a navigation system display.

6. The vehicle-based computing apparatus of claim 4, wherein the vehicle display is a radio head display.

7. The vehicle-based computing apparatus according to one of claims 2 to 6, wherein the create phrase command further includes a plurality of text strings to be listened for by the vehicle-based computing system through a microphone input, wherein the processor is operable to process microphone input to determine if the input matches a text string; and

wherein, if the input is determined to be matched to a text string, the processor is operable to return an identifier to the nomadic device, through the transceiver, identifying which text string was matched.

8. The vehicle-based computing apparatus of claim 7, wherein the processor is further able to determine a degree-of-confidence with which an input matches a text string.
9. The vehicle-based computing apparatus of claim, wherein the processor does not return an identifier identifying which text string was matched unless the degree-of-confidence is above a predetermined threshold.
10. The vehicle-based computing apparatus according to one of claims 2 to 9, wherein the prompt and listen command further includes a first string of text to be used to prompt a vehicle occupant, and wherein if a the prompt and listen command is received by the processor, the processor is further operable to instruct at least one of a vehicle display and a vehicle audio system to output the first string of text in displayed and/or spoken format.
11. The vehicle-based computing apparatus of claim 10, wherein the processor is further operable to obtain a priority right over at least one of the display and audio system for the purposes of outputting the first string of text.
12. The vehicle-based computing apparatus of claim 11, wherein the prompt and listen command further includes a second string of text to be used to help a vehicle occupant, wherein the processor is operable to listen, through a microphone, for a help request, and wherein if the processor receives a help request, the processor is further operable to instruct at least one of a vehicle display and a vehicle audio system to output the second string of text in displayed and/or spoken format.
13. The vehicle-based computing apparatus of claim 11 or 12, wherein the prompt and listen command further includes a third string of text to be used to reject user input, wherein the processor is operable to listen, through a microphone, for user input, and wherein if the processor receives user input that the processor is unable to properly handle, the processor is further operable to instruct at least one of a vehicle display and a vehicle audio system to output the third string of text in displayed and/or spoken format.

14. A method of communication between an application stored on a wireless device and a vehicle-based computing system comprising, in particular for using in conjunction with a vehicle-based computing apparatus according to one of the preceding claims:

receiving, at the vehicle-based computing system, a request initiated by the application to connect the application to the vehicle-based computing system;
establishing communication between the vehicle-based computing system, and the application;
receiving, at the vehicle-based computing system, at least a second request, the second request including at least one secondary communication pertaining to the operation of the application.
