C-ARYL GLUCOSIDE SGLT2 INHIBITORS AND METHOD

Field of the Invention

The present invention relates to C-aryl glucosides which are inhibitors of sodium dependent glucose transporters found in the intestine and kidney (SGLT2) and to a method for treating diabetes, especially type II diabetes, as well as hyperglycemia, hyperinsulinemia, obesity, hypertriglyceridemia, Syndrome X, diabetic complications, atherosclerosis and related diseases, employing such C-aryl glucosides alone or in combination with one, two or more other type antidiabetic agent and/or one, two or more other type therapeutic agents such as hypolipidemic agents.

Background of the Invention

Approximately 100 million people worldwide suffer from type II diabetes (NIDDM), which is characterized by hyperglycemia due to excessive hepatic glucose production and peripheral insulin resistance, the root causes for which are as yet unknown. Hyperglycemia is considered to be the major risk factor for the development of diabetic complications, and is likely to contribute directly to the impairment of insulin secretion seen in advanced NIDDM. Normalization of plasma glucose in NIDDM patients would be predicted to improve insulin action, and to offset the development of diabetic complications. An inhibitor of the sodium-dependent glucose transporter SGLT2 in the kidney would be expected to aid in the normalization of plasma glucose levels, and perhaps body weight, by enhancing glucose excretion.

The development of novel, safe, and orally active antidiabetic agents is also desired in order to...
complement existing therapies, including the sulfonylureas, thiazolidinediones, metformin, and insulin, and to avoid the potential side effects associated with the use of these other agents.

Hyperglycemia is a hallmark of type II diabetes (NIDDM); consistent control of plasma glucose levels in diabetes can offset the development of diabetic complications and beta cell failure seen in advanced disease. Plasma glucose is normally filtered in the kidney in the glomerulus and actively reabsorbed in the proximal tubule. SGLT2 appears to be the major transporter responsible for the reuptake of glucose at this site. The SGLT specific inhibitor phlorizin or closely related analogs inhibit this reuptake process in diabetic rodents and dogs resulting in normalization of plasma glucose levels by promoting glucose excretion without hypoglycemic side effects. Long term (6 month) treatment of Zucker diabetic rats with an SGLT2 inhibitor has been reported to improve insulin response to glycemia, improve insulin sensitivity, and delay the onset of nephropathy and neuropathy in these animals, with no detectable pathology in the kidney and no electrolyte imbalance in plasma. Selective inhibition of SGLT2 in diabetic patients would be expected to normalize plasma glucose by enhancing the excretion of glucose in the urine, thereby improving insulin sensitivity, and delaying the development of diabetic complications.

Ninety percent of glucose reuptake in the kidney occurs in the epithelial cells of the early S1 segment of the renal cortical proximal tubule, and SGLT2 is likely to be the major transporter responsible for this reuptake. SGLT2 is a 672 amino acid protein containing 14 membrane-spanning segments that is predominantly expressed in the early S1 segment of the renal proximal tubules. The substrate specificity, sodium dependence,
and localization of SGLT2 are consistent with the properties of the high capacity, low affinity, sodium-dependent glucose transporter previously characterized in human cortical kidney proximal tubules. In addition, hybrid depletion studies implicate SGLT2 as the predominant Na\(^+\)/glucose cotransporter in the S1 segment of the proximal tubule, since virtually all Na-dependent glucose transport activity encoded in mRNA from rat kidney cortex is inhibited by an antisense oligonucleotide specific to rat SGLT2. SGLT2 is a candidate gene for some forms of familial glucosuria, a genetic abnormality in which renal glucose reabsorption is impaired to varying degrees. None of these syndromes investigated to date map to the SGLT2 locus on chromosome 16. However, the studies of highly homologous rodent SGLTs strongly implicate SGLT2 as the major renal sodium-dependent transporter of glucose and suggest that the glucosuria locus that has been mapped encodes an SGLT2 regulator. Inhibition of SGLT2 would be predicted to reduce plasma glucose levels via enhanced glucose excretion in diabetic patients.

SGLT1, another Na-dependent glucose cotransporter that is 60% identical to SGLT2 at the amino acid level, is expressed in the small intestine and in the more distal S3 segment of the renal proximal tubule. Despite their sequence similarities, human SGLT1 and SGLT2 are biochemically distinguishable. For SGLT1, the molar ratio of Na\(^+\) to glucose transported is 2:1, whereas for SGLT2, the ratio is 1:1. The \(K_m\) for Na\(^+\) is 32 and 250-300 mM for SGLT1 and SGLT2, respectively. \(K_m\) values for uptake of glucose and the nonmetabolizable glucose analog \(\alpha\)-methyl-D-glucopyranoside (AMG) are similar for SGLT1 and SGLT2, i.e. 0.8 and 1.6 mM (glucose) and 0.4 and 1.6 mM (AMG) for SGLT1 and SGLT2 transporters, respectively.
However, the two transporters do vary in their substrate specificities for sugars such as galactose, which is a substrate for SGLT1 only.

Administration of phlorizin, a specific inhibitor of SGLT activity, provided proof of concept in vivo by promoting glucose excretion, lowering fasting and fed plasma glucose, and promoting glucose utilization without hypoglycemic side effects in several diabetic rodent models and in one canine diabetes model. No adverse effects on plasma ion balance, renal function or renal morphology have been observed as a consequence of phlorizin treatment for as long as two weeks. In addition, no hypoglycemic or other adverse effects have been observed when phlorizin is administered to normal animals, despite the presence of glycosuria.

Administration of an inhibitor of renal SGLTs for a 6-month period (Tanabe Seiyaku) was reported to improve fasting and fed plasma glucose, improve insulin secretion and utilization in obese NIDDM rat models, and offset the development of nephropathy and neuropathy in the absence of hypoglycemic or renal side effects.

Phlorizin itself is unattractive as an oral drug since it is a nonspecific SGLT1/SGLT2 inhibitor that is hydrolyzed in the gut to its aglycone phloretin, which is a potent inhibitor of facilitated glucose transport.

Concurrent inhibition of facilitative glucose transporters (GLUTs) is undesirable since such inhibitors would be predicted to exacerbate peripheral insulin resistance as well as promote hypoglycemia in the CNS.

Inhibition of SGLT1 could also have serious adverse consequences as is illustrated by the hereditary syndrome glucose/galactose malabsorption (GGM), in which mutations in the SGLT1 cotransporter result in impaired glucose uptake in the intestine, and life-threatening diarrhea and dehydration. The biochemical differences between
SGLT2 and SGLT1, as well as the degree of sequence divergence between them, allow for identification of selective SGLT2 inhibitors.

The familial glycosuria syndromes are conditions in which intestinal glucose transport, and renal transport of other ions and amino acids, are normal. Familial glycosuria patients appear to develop normally, have normal plasma glucose levels, and appear to suffer no major health deficits as a consequence of their disorder, despite sometimes quite high (110-114 g/daily) levels of glucose excreted. The major symptoms evident in these patients include polyphagia, polyuria and polydipsia, and the kidneys appear to be normal in structure and function. Thus, from the evidence available thus far, defects in renal reuptake of glucose appear to have minimal long term negative consequences in otherwise normal individuals.

Assay for SGLT2 Activity

The mRNA sequence for human SGLT2 (GenBank #M95549) was cloned by reverse-transcription and amplification from human kidney mRNA, using standard molecular biology techniques. The cDNA sequence was stably transfected into CHO cells, and clones were assayed for SGLT2 activity essentially as described in Ryan et al. (1994). Evaluation of inhibition of SGLT2 activity in a clonally selected cell line was performed essentially as described in Ryan et al., with the following modifications. Cells were grown in 96-well plates for 2-4 days to 75,000 or 30,000 cells per well in F-12 nutrient mixture (Ham's F-12), 10% fetal bovine serum, 300 μg/ml Geneticin and penicillin-streptomycin. At confluence, cells were washed twice with 10 mM Hepes/Tris, pH 7.4, 137 mM N-methyl-D-glucamine, 5.4 mM KCl, 2.8 mM CaCl₂, 1.2 mM MgSO₄. Cells then were incubated with 10 μM [¹⁴C]AMG, and 10 μM inhibitor (final DMSO =0.5%) in 10 mM Hepes/Tris, pH 7.4, 137 mM NaCl, 5.4 mM KCl, 2.8 mM CaCl₂, 1.2 mM MgSO₄ at 37°C for 1.5 hr. Uptake assays were quenched with ice cold 1X PBS containing 0.5 mM phlorizin, and cells were then lysed with 0.1% NaOH. After addition of MicroScint
scintillation fluid, the cells were allowed to shake for 1 hour, and then [14C]AMG was quantitated on a TopCount scintillation counter. Controls were performed with and without NaCl. For determination of EC₅₀ values, 10 inhibitor concentrations were used over 2 log intervals in the appropriate response range, and triplicate plates were averaged across plates.

The following Working Examples represent preferred embodiments of the present invention. All temperatures are expressed in degrees Centigrade unless otherwise indicated.

![Chemical Structure]

A. 3-Bromo-4′-ethylbenzylhydrol

Dry Mg turnings (4.4g, 0.178 mol) under Ar were stirred overnight whereupon 100 mL of dry Et₂O was added followed by addition over 1 hr of p-bromoethylbenzene (22g, 0.119 mol) in 20 mL of Et₂O. (In the event the reaction did not start, 0.5 ml of 1,2-dibromoethane was added). After stirring overnight, m-bromobenzaldehyde (11g, 0.06 mol) in 20 mL of Et₂O was slowly added. The resulting light solution was monitored by HPLC over 4-6
hr to determine when complete. The reaction, after quenching with saturated aq. NH₄Cl, was extracted 3x with EtOAc. The combined organic layers were washed with brine, dried over Na₂SO₄ and concentrated using a rotary evaporator. The resulting yellow oil was chromatographed on silica gel using 5% EtOAc/hexane to elute nonpolar impurities and 7-9% EtOAc/hexane to elute 12.4 g (71%) of 3-bromo-4’-ethylbenzhydrol as a light yellow oil.

B. 3-Bromo-4’-ethyldiphenylmethane
To a stirred -30° solution of Part A 3-bromo-4’-ethylbenzhydrol (12.4g, 0.0426 mol) in 120 mL of MeCN was added BF₃·Et₂O (6.04g, 0.0426 mol) followed by Et₃SiH (9.9g, 0.852 mol). The dark reaction after stirring 1 hr at -30° was warmed slowly to -5°. When complete by tlc, the reaction was quenched by addition of saturated aq. K₂CO₃. After addition of 100 mL of H₂O, the mixture was extracted 3x with Et₂O. The combined organic layers were washed with brine, dried over Na₂SO₄. After concentration using a rotary evaporator, 3-bromo-4’-ethyldiphenylmethane (11.17g, 95%) was obtained as a light yellow oil that was used without further purification.

To a stirred -78° solution of Part B 3-bromo-4’-ethyldiphenylmethane (10.9g, 0.04 mol) in 100 mL of dry THF under Ar was added 25.7 mL of 1.7 M t-BuLi in hexane over 20 min. After 1hr 2,3,4,6-tetra-O-benzyl-β-D-
glucolactone (23.5 g, 0.0437 mol) in 30 mL of THF was added over 15 min. The solution was stirred for 1 hr at -78° prior to quenching with saturated aq. NH₄Cl. After warming to 20°, the reaction was diluted 2 fold with EtOAc prior to washing with H₂O followed by brine. After drying over Na₂SO₄ and concentration using a rotary evaporator, 29.2 g of the desired title lactol was obtained as a colorless syrup that was carried forward without further purification.

![Chemical Structure](image)

To a stirred -30° solution of Part C lactol (29.1g, 0.04 mol) in 100 mL of MeCN was added BF₃·Et₂O (5.62g, 0.04 mol) followed by Et₃SiH (9.21g, 0.08 mol). After 2 hr, when tlc showed the reaction to be complete, saturated aq. K₂CO₃ was added and the suspension stirred 1 hr at 20° prior to diluting with H₂O and Et₂O. The combined organic layers from 3 Et₂O extractions were washed with brine, dried over Na₂SO₄, and concentrated using a rotary evaporator to yield 28.3 g of a light yellow syrup. Chromatography on silica gel with 5% EtOAc/hexane eluted nonpolar impurities followed slowly by the desired beta anomer and then the alpha anomer. Fractions enriched in the beta anomer could be further purified by either triterating with hexane or by recrystallization from EtOH to yield 6 g of the desired title beta tetra-O-benzyl C-glucoside. (Note when Et₃SiH is the reducing agent, a 5:1 beta/alpha anomer mixture is...
obtained whereas when iPr$_3$SiH is substituted a 30:1 mixture is obtained.)

E.

A mixture of o-toluic acid (28g, 206mmol), iron powder (0.74g, 13mmol), and Br$_2$ (42g, 260 mmol) were stirred at 0° for 2 hr. At this point the reaction, which had proceeded ~40%, was diluted with 25 mL of CH$_2$Cl$_2$ to facilitate stirring. The reaction was then heated at 45° for 16 hr to drive to completion. Upon cooling, the reaction was diluted with CH$_2$Cl$_2$, washed 2x with 10% NaHSO$_3$, 1x with brine prior to drying over Na$_2$SO$_4$. After removal of the volatiles, the residue comprising a 2:1 mixture of 5-bromo to 3-bromotoluic acid was recrystallized from 95% EtOH to yield 14.4g of 5-bromo-2-methylbenzoic acid.

vigor. evolution of gas ceased, the reaction was
stirred 6 hr prior to removal of the volatiles using a
