INDENONE DERIVATIVE AND PHARMACEUTICAL COMPOSITION COMPRISING SAME

FIELD OF THE INVENTION

The present invention relates to an indenone derivative and a pharmaceutical composition comprising the same which is used for preventing or treating bone diseases such as osteoporosis.

BACKGROUND OF THE INVENTION

Osteoporosis is caused by reduced bone mass, leading to weakening of the bone strength and an increased risk of bone fracture. The bone mass is controlled by the continuous bone resorption and bone formation processes. The peak bone mass is achieved at about 25 ages in healthy people, and decreases slowly with advancing age. Women generally have a lower bone mass than men, and the bone loss becomes increasing more pronounced after menopause. Ten million people are presumed to suffer from osteoporosis in U.S., and about thirty-four million people in the world have the problem of low bone mass, and they are under the risk of osteoporosis. Clinical studies showed that the death rate within two years from the appearance of symptoms of osteoporosis is currently about 12%, and many osteoporosis patients (about 30%) are faced to stay home due to bone fracture. Recently, the number of osteoporosis patients has increased due to the aging of global population, and accordingly, there has existed a need for developing an efficacious medicament for preventing and treating osteoporosis.

Bone is a living tissue which is composed of several different types of cells. In healthy individuals, the amount of bone removed or resorbed by the osteoclastic cells is compensated by new bone made by the osteoblastic cells. The overall bone formation and bone resorption occur to the extent of about 14% of bones over a year to maintain a steady bone mass, but for individuals suffering from a bone-resorbing disease, such balance cannot be achieved. In women, about 5% a year bone loss from the spine occurs after menopause. Such symptom has been attributed to estrogen deficiency associated with menopause. However, the question as to what mechanism is involved between the loss of estrogen and increased bone resorption remains unresolved.
In order to reduce the risk of bone fracture, various methods for maintaining or increasing the bone mass are currently used, by reducing the bone resorption rate, increasing the bone formation rate, or a combination thereof. As therapeutic agents for blocking bone resorption, integrin $\alpha_v\beta_3$ antagonists, cathepsin K inhibitors, and inhibitors against OPG/PANKL/RANK system have been investigated. Further, as therapeutic agents for enhancing the bone formation, parathyroid hormones and their derivatives structure have been reported. Exemplary therapeutic agents include new parathyroid hormonal products, calcium sensing receptor antagonists which regulate the secretion of parathyroid hormone, selective androgen receptor modulators (SARMs), growth hormone secretagogues, insulin-like growth elements, proteosome inhibitors, and statins.

The currently methods for treating bone loss generally involve the administration of compounds such as estrogen, bisphosphonates, calcitonin, and raloxifene. These compounds, however, are generally used for long-term treatments, and they induce undesirable side effects. Further, such treatments are typically directed to the activity of mature osteoclasts, rather than reducing their formation. For example, estrogen induces the apoptosis of osteoclasts, while calcitonin causes the osteoclasts to shrink and detach from the bone surface (Hughes et al., Nat. Med. 2:1132-1136, 1996; Jilka et al., Exp. Hematol. 23:500-506, 1995). Similarly, bisphosphonates reduce the osteoclast activity, change their morphology, and increase the apoptosis of osteoclasts (Parfitt et al., J. Bone Miner Res. 11:150-159, 1996; Suzuki et al., Endocrinology 137: 4685-4690, 1996).

Currently available therapeutic agents for treating osteoporosis include bisphosphonates, hormonal drugs, vitamin D and its analogues, calcitonin, and calcium. Representative bisphosphonates include alendronate (Merck Co., Ltd.), risedronate (Hoffman-La Roche Ltd.), zoledronate (Novartis AG; EP Patent No. 275,821), ibandronate (Hoffman-La Roche Ltd.; US Patent No. 4,942,157), and minodronate (Yamanouchi Pharmaceutical Co., Ltd.; EP Patent No. 354,806). Bisphosphonates, however, suffers from the problems of low absorption rates through the gastrointestinal tract (10% or less) and the tendency to cause esophagitis when the patients do not follow the complicated administration guidance. In particular, it has been reported that alendronate causes some side effects, e.g., gastrointestinal disorders and osteonecrosis of the jaw, besides the fact that long-term administration of bisphosphonates osteonecrosis. Accordingly, novel therapeutic agents for osteoporosis are required.
Exemplary hormonal drugs include raloxifene (Eli Lilly Co.), droloxifene (Pfizer Inc.; EP Patent No. 54168), lasopoxifene (Pfizer Inc.; WO 97/16434), FC-1271 (homosmedical Co. and Orion Corp.; WO 96/07402), TES-424 (Ligand Co. and Weyers Co.; US Patent No. 5,948,755), and SERMs, which are at the stage of clinical studies. However, these drugs bring the risk of causing breast or uterine cancer, and accordingly, they are not suitable for use as a therapeutic agent for osteoporosis which requires a long-term administration.

Further, vitamin D and its analogues are expensive and its therapeutic efficacy for osteoporosis is not clearly established; calcitonin is relatively expensive and requires a complicated administration procedure; and calcium is effective only for the prevention of osteoporosis, having no therapeutic effect.

**Experimental Example**

**Experimental Example 1: Effects of the inventive indenone derivatives on differentiation of osteoblast cells**

To examine the effects of the inventive indenone derivatives on the differentiation and activation of osteoblast cells, the activity and expression of alkaline phosphatase (ALP), a marker for the differentiation of osteoblast cells, and the bone nodule formation using a mouse derived osteoblast-like cells, MC3T3-E1 (ATCC, Japan) or a primary mouse calvaria derived preosteoblastic cells were observed.

MC3T3-E1 cells were seeded in a medium containing osteogenic factors (OF) such as ascorbic acids and β-glycerophosphates (b-GP), and each compound of Examples was added thereto at a concentration of 0.1, 1 and 10 μM. The cells were incubated for 6 days (MC3T3-E1 cells) or 7 days (primary mouse calvaria derived preosteoblastic cells) in a 37°C CO₂ incubator. Then, the culture medium was replaced with a fresh medium together with the test compound every two or three days. On the last day, the medium was centrifuged to remove the supernatant, and the cells were washed with PBS. The washed cells were subjected to a 3-cycle freeze-thaw treatment using a -70°C deep freezer to allow enzymes elute in a lysis buffer. The lysed protein was quantified, followed by measurement of ALP activity using 4-nitrophenylphosphate. The results are shown in Table 1.

Further, a group treated only with DMSO or OF was tested for ALP activities for comparison. The group treated only with DMSO did not show any ALP activity. In addition, the group treated only with OF showed an ALP activity, which was lower than that of the group treated with the inventive compound together with OF. In contrast, a group treated with the inventive compound together with OF showed more than 100% of activity, based on the ALP activity of the group treated with only OF, the activity being dependent on the concentration of the compound.

Meanwhile, the bone nodule formation involving osteogenesis was evaluated using the Alizarin red-S staining method in which coloring occurs due to the reaction of accumulated calcium as well as the coloring due to the reaction with arenazo III by way of measuring the value of absorbance. As a result, red cells formed by the reaction with alizarin red-S were minor degree for the group treated only with OF, while markedly increased red cells were observed for the group treated with the inventive compound and
OF, the degree of increase being dependent on the concentration of the treated compound. In absorbance results, the groups treated with the inventive compounds showed more than 100%, based on the group treated only with OF, the absorbance being dependent on the concentration of treated compound.

**Experimental Example 2: Effects of the indenone derivatives on formation and activity of the osteoclast cells**

To investigate the effects of the indenone derivatives on the osteoclast formation, the TRAP (tartrate-resistant acid phosphatase) activity was measured using mouse primary bone marrow cells and Raw264.7 cells (TIB-71™, ATCC, U.S).

RANKL (receptor activator of NF-kappa B ligand), which is essential to mouse primary bone marrow cells and Raw264.7 cells, is known to control the differentiation of osteoclast cells. To evaluate the inhibitory effects of the indenone derivative on osteoclast cells, TRAP staining and measurement of TRAP activity were conducted on day 5 after treatment of the inventive indenone derivative at various concentrations of 0.1, 1, 10, and 100 µM together with RANKL. The results are shown in Fig. 1 and Table 1.

1) ALP activity- MC3T3E1 cells treated with 10μM of the compound of Example 1 and OF
2) TRAP activity- Raw264.7 cells treated with 10μM of the compound of Example 1 and RANKL
In Table 1, the ALP activity refers to osteoclast activity involving osteogenesis, of which the higher value indicates the treat compound being more efficacious, and the TRAP activity means osteoclast activity facilitating the bone resorption, of which the lower value indicates the treated compound being more efficacious.

As shown in Fig. 1, the inhibitory effects of the compounds on the bone resorption by the osteoclastic cells are dependent on the concentration of the treated compound.

Experimental Example 3: Effects of the indenone derivatives on osteogenesis in vivo

The bone formation is regulated via the synthesis of bone matrix formed upon differentiation of osteoclast cells. To evaluate the effects of the indenone derivatives of the present invention on osteogenesis, the skull of SD rat was exposed in a size of 6 mm diameter and to the collagen sponge thereof, 0.5 mg of compound of Example 1 was treated, followed by suturing the epidermis. Two weeks later, the rat was sacrificed, and the skull was extracted to observe the bone formation using micro-CT. Further, the skull treated with a vehicle as a control and the skull treated with 2μg of BMP-2, which facilitates bone formation, as a positive control were observed according to the same procedure.

The results are shown in Fig. 2. As shown in Fig. 2, the indenone derivatives of the present invention is effective in bone formation, compared to the controls.

Experimental Example 4: Effects of the indenone derivatives on the bone resorption in vivo

Most pharmacological effectiveness of therapeutic agents for osteoporosis has been evaluated using an animal, rather than a human. Particularly, as a model animal for osteoporosis occurring after menopause, ovariectomized female rats have been used for its similarity to women after menopause. To examine the effects of the indenone derivatives on the bone resorption, female SD rats and female DDY mice were subjected to ovariectomy. After the rats or mice were anesthetized by abdominally injecting 25 mg/kg of sodium pentobarbital (Choongwae pharma coporation), the fur of the abdominal region was shaved and the operation area was sterilized. About 1.5 cm of abdominal skin, abdominal muscle, and peritoneum were cut in the middle under aseptic condition, and ovary was exposed, followed by removal of both left and right ovaries after ligaturing of
oviducts using silk threads. Then, peritoneum, abdominal muscle and skin were sutured with silk threads. The Sham group, animals operated upon for the surgery as in the ovariectomized rats except for removing ovary, was employed to compare the effects.

To examine whether the indenone derivative have the effect on osteoporosis models, the compound of Example 1 was orally administered once a day for 4 weeks in a various concentrations, followed by analysis of the bone density, using high resolution in-vivo micro-CT system (explore Locus scanner, GE Health Care, U.S.; scan resolution: 45μm).

As shown in FIGS. 3A and 3B, the bone densities decreased by ovariectomy were significantly increased by the 4 weeks-administration of the indenone derivative of Example 1.

While the invention has been described with respect to the above specific embodiments, it should be recognized that various modifications and changes may be made to the invention by those skilled in the art which also fall within the scope of the invention as defined by the appended claims.
