Title: AUTOMATED MATERIAL HANDLING SYSTEM FOR SEMICONDUCTOR MANUFACTURING BASED ON A COMBINATION OF VERTICAL CAROUSELS AND OVERHEAD HOISTS

Abstract: A highly efficient Automated Material Handling System (AMHS) that allows an overhead hoist transport vehicle to load and unload Work-In-Process (WIP) parts directly to/from one or more WIP storage units included in the system. The AMHS includes an overhead hoist transport subsystem and at least one vertical carousel stocker having a plurality of storage bins. The overhead hoist transport subsystem includes an overhead hoist transport vehicle traveling along a suspended track defining at least one predetermined route. The predetermined route passes over the vertical carousel stocker, which allows the overhead transport vehicle to access one or more WIP parts directly from one of the carousel storage bins. The selected carousel storage bin is positioned at the top of the vertical carousel stocker underneath the suspended track. Next, the overhead hoist transport vehicle is moved along the suspended track to a position above the selected carousel storage bin. The overhead hoist is then lowered parallel to the longitudinal axis of the vertical carousel stocker toward the selected storage bin. Finally, the overhead hoist is operated to pick the desired WIP lot directly from the carousel storage bin, or to place one or more WIP lots in the storage bin.
TITLE OF THE INVENTION

AUTOMATED MATERIAL HANDLING SYSTEM FOR SEMICONDUCTOR MANUFACTURING
BASED ON A COMBINATION OF VERTICAL CAROUSELS AND OVERHEAD HOISTS

CROSS REFERENCE TO RELATED APPLICATIONS

This application claims priority of U.S. Provisional Patent Application No. 60/389,993 filed June 19, 2002 entitled AUTOMATED MATERIAL HANDLING SYSTEM FOR SEMICONDUCTOR MANUFACTURING BASED ON A COMBINATION OF VERTICAL CAROUSELS AND OVERHEAD HOISTS, and U.S. Provisional Patent Application No. 60/417,993 filed October 11, 2002 entitled OFFSET ZERO FOOTPRINT STORAGE (ZFS) USING MOVING SHELVES OR A TRANSLATING HOIST PLATFORM.

BACKGROUND OF THE INVENTION

The present invention relates generally to automated material handling systems, and more specifically to an automated material handling system that allows an overhead hoist to access work-in-process (WIP) parts directly from a WIP storage unit to increase the efficiency of the overall material handling system.

Automated material handling systems are known that employ WIP storage units and overhead hoists to store and transport WIP parts between various workstations and/or processing machines in a product manufacturing environment. For example, such an Automated Material Handling System (AMHS) is commonly employed in the manufacturing of Integrated Circuit (IC) chips. A typical process
for fabricating an IC chip comprises various steps including deposition, cleaning, ion implantation, etching, and passivation steps. Further, each of these steps in the IC chip fabrication process is usually performed by a different processing machine such as a chemical vapor deposition chamber, an ion implantation chamber, or an etcher. Accordingly, the WIP parts, e.g., semiconductor wafers, are typically transported between the different workstations and/or processing machines multiple times to perform the various process steps required for fabricating the IC chips.

A conventional AMHS for manufacturing IC chips comprises a plurality of WIP storage units (also known as "stockers") for storing the semiconductor wafers, and one or more overhead hoist transport vehicles for transporting the wafers between the various workstations and processing machines on the IC chip manufacturing floor. The semiconductor wafers stored in the WIP stockers are typically loaded into cassette pods such as Front Opening Unified Pods (FOUPs), which are subsequently transferred to an overhead transport vehicle configured to travel on a suspended track. In the conventional AMHS, each stocker is typically provided with a plurality of active input/output ports that work in conjunction with an internal robotic arm (which may provide up to three or more axes of movement) for loading and unloading the FOUPs to/from the stocker. The FOUPs are picked and placed from/to the input/output ports by the overhead hoist vehicle.

One drawback of the conventional AMHS is that the efficiency of the overall system is limited by the time required for the robotic arm to access the FOUPs at the WIP stocker’s active input/output ports. Because of the generally delicate nature of the semiconductor wafers, strict limits are normally imposed on the acceleration rate of the robotic arm. For this reason, a minimum amount of time is typically required for moving the FOUPs...
to and from the stocker’s input/output ports. This minimum move time generally determines the stocker throughput, which dictates the number of stockers needed to support the desired IC chip production level and thus the total cost of the AMHS. Although the material handling efficiency of the AMHS might be improved by increasing the number of active input/output ports on each stocker and by allowing the overhead transport vehicle to access multiple input/output ports simultaneously, providing additional input/output ports can significantly increase the cost of the stocker.

In addition, the combination of a three or more axis internal robot in the stocker with several input/output ports, each having 1-3 axes of motion, means that a typical stocker may have between 5 and 16 axes of motion. This is a very complex, low reliability, and costly solution for storing material.

It would therefore be desirable to have an automated material handling system that provides enhanced material handling efficiency while overcoming the drawbacks of conventional automated material handling systems.

BRIEF SUMMARY OF THE INVENTION

In accordance with the present invention, a highly efficient Automated Material Handling System (AMHS) is provided that allows an overhead hoist to load and unload Work-In-Process (WIP) parts directly to/from one or more WIP storage units included in the system.

In one embodiment, the improved AMHS comprises an overhead hoist transport subsystem and at least one vertical carousel WIP storage unit ("stocker") including a plurality of storage bins. The overhead hoist transport subsystem includes at least one overhead hoist transport vehicle configured to travel along a suspended track defining at least one predetermined route. The
predetermined route passes over the vertical carousel stocker, which is configured to allow the overhead hoist to access one or more WIP parts directly from a selected one of the carousel storage bins. In this first embodiment, the selected carousel storage bin containing the desired WIP lot(s) is positioned at the top of the vertical carousel stocker substantially directly underneath the suspended track. Next, the overhead hoist transport vehicle is moved along the suspended track to a position substantially directly above the selected carousel storage bin. The overhead hoist is then lowered toward the selected storage bin. Finally, the overhead hoist is operated to pick the desired WIP lot directly from the carousel storage bin, or to place one or more WIP lots in the carousel storage bin.

In a second embodiment, the predetermined route defined by the suspended track passes parallel to the vertical carousel WIP stocker, which is configured to allow the overhead hoist to access one or more WIP parts directly from one of the carousel storage bins. The AMHS further includes an extraction mechanism, which works in conjunction with the vertical carousel stocker to suitably position the selected carousel storage bin containing the desired WIP lot(s) relative to the track. For example, the extraction mechanism may be configured to move the selected carousel storage bin (e.g., a movable shelf) along a single servo-controlled axis from a first position adjacent the track to a second position substantially directly underneath the track.

In the second embodiment, the overhead transport vehicle is moved along the track to a position substantially directly above the second position. Next, the overhead hoist is lowered toward the second position. In an alternative embodiment, the selected carousel storage bin comprises a shelf positioned alongside the track, and the overhead hoist is mounted to a translating stage for picking and placing one or more WIP lots to the shelf at the
side of the overhead transport vehicle. Finally, the overhead hoist is operated to pick the desired WIP lot directly from the selected storage bin, or to place one or more WIP lots in the selected storage bin.

By configuring the AMHS to allow the overhead hoist to directly load and unload WIP parts to/from the carousel storage bins from a position above the respective storage bin, more efficient AMHS operation can be achieved.

Other features, functions, and aspects of the invention will be evident from the Detailed Description of the Invention that follows.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

The invention will be more fully understood with reference to the following Detailed Description of the Invention in conjunction with the drawings of which:

DETAILED DESCRIPTION OF THE INVENTION

U.S. Provisional Patent Application No. 60/389,993 filed June 19, 2002 entitled AUTOMATED MATERIAL HANDLING SYSTEM FOR SEMICONDUCTOR MANUFACTURING BASED ON A COMBINATION OF VERTICAL CAROUSELS AND OVERHEAD HOISTS and U.S. Provisional Patent Application No. 60/417,993 filed October 11, 2002 entitled OFFSET ZERO FOOTPRINT STORAGE (ZFS) USING MOVING SHELVES OR A TRANSLATING HOIST PLATFORM are incorporated herein by reference.

An Automated Material Handling System (AMHS) is disclosed that can load and unload Work-In-Process (WIP) parts to/from a WIP storage unit with increased efficiency. The presently disclosed AMHS achieves such increased material handling efficiency by allowing top-loading/unloading of storage bins in a vertical carousel WIP storage unit by an overhead hoist positioned above the respective storage bin.

Fig. 1 depicts a conventional AMHS 100, which may be employed to automatically store and transport WIP parts between various workstations and/or processing machines in a product manufacturing environment, e.g., a clean environment for manufacturing Integrated Circuit (IC) chips. As shown in Fig. 1, the conventional AMHS 100 comprises a WIP storage unit ("stocker") 102 and an overhead hoist transport subsystem 104. The WIP stocker 102 includes input and output ports 111-112, and the overhead hoist transport subsystem 104 includes a suspended track 108 and a plurality of overhead hoist transport vehicles 105-106 configured to travel on the track 108. In a typical mode of operation, the WIP parts are transported in a cassette pod 110 such as a Front Opening Unified Pod (FOUP). The first overhead transport vehicle 105 travels along the track 108 and stops at a position suitable for unloading the FOUP 110 into the input port 111 or for loading another FOUP from the output port 112 of the
stocker 102. Further, the second overhead transport vehicle 106 waits on the track 108 until the first overhead transport vehicle 105 finishes unloading/loading the FOUP and moves out of the way.

In the conventional AMHS 100, FOUPs are unloaded from the overhead hoist into the input port 111, loaded from the output port 112 into the overhead hoist, or otherwise accessed from within the stocker 102 by a robotic arm 107, which may provide up to three or more axes of movement. Further, the minimum amount of time required to access the FOUPs from the stocker 102 generally determines the stocker throughput, which dictates the number of stockers needed to support the desired production level. Accordingly, complex movements of the multi-axis robotic arm 107 for accessing the FOUPs may cause the minimum move time to increase, thereby increasing both the number of stockers needed in the AMHS 100 and the overall cost of the material handling system.

Fig. 2 depicts an illustrative embodiment of an Automated Material Handling System (AMHS) 200, in accordance with the present invention. In the illustrated embodiment, the AMHS 200 comprises an overhead hoist transport subsystem 204, and at least one vertical carousel WIP storage unit ("stocker") 202 including a plurality of storage bins such as a carousel storage bin 203. The vertical carousel WIP stocker 202 is configured to allow an overhead hoist in the overhead hoist transport subsystem 204 to access WIP parts directly from a selected one of the carousel storage bins.

It is noted that like the conventional AMHS 100 (see Fig. 1), the AMHS 200 of Fig. 2 may be employed in a clean environment for manufacturing IC chips such as a 200 mm or 300 mm FAB plant, or any other suitable product manufacturing environment. As shown in Fig. 2, the IC chip manufacturing environment includes first and second floors 220 and 226, and a ceiling 214. The
first floor 220 typically comprises a waffle slab made of reinforced concrete, and the second floor 226 comprises a raised floor located above the waffle slab 220. The vertical carousel stocker 202 is positioned on the waffle slab 220. Further, workstations and/or processing machines (not shown) configured to perform various process steps for fabricating the IC chips are positioned on the raised floor 226, which is typically covered with an electrically nonconductive material and designed to meet specific loading and seismic requirements. For example, the raised floor 226 may be located a distance 228 (about 0.6 m) above the waffle slab 220 and a distance 224 (greater than or equal to about 4.15 m) below the ceiling 214.

In the presently disclosed embodiment, the vertical carousel stocker 202 includes a housing 252, and first and second pulleys 250-251 and a belt 254 disposed within the housing 252. As shown in Fig. 2, the carousel storage bins (e.g., the storage bin 203) are coupled to the belt 254 at various spaced locations along the belt, and the belt 254 is looped between the first and second pulleys 250-251 to allow the storage bins to be rotatably positioned along the belt path by driving one of the pulleys 250-251. For example, the vertical carousel stocker 202 may have a height 218 (about 3.85 m). The top of the vertical carousel stocker 202 may therefore be a distance 216 (about 3.25 m) above the raised floor 226.

As described above, the vertical carousel stocker 202 is configured to allow an overhead hoist to access WIP parts, e.g., semiconductor wafers, directly from one of the carousel storage bins. In the illustrated embodiment, the portion of the stocker housing 252 near the ceiling 214 is at least partially open to allow top-loading/unloading of the selected carousel storage bin. Further, each carousel storage bin comprises a fixed shelf, and the semiconductor wafers are loaded into cassette pods such as a
Front Opening Unified Pod (FOUP) 210 disposed on the shelf 203. For example, each FOUP 210 may hold one or more semiconductor wafer lots, thereby allowing the overhead hoist to access multiple wafer lots in a single carousel storage bin simultaneously.

The overhead hoist transport subsystem 204 includes a suspended track 208 and at least one overhead hoist transport vehicle 205 configured for traveling on the track 208. The suspended track 208 defines at least one predetermined route passing over the vertical carousel stocker 202, thereby allowing the overhead transport vehicle 205 to access a FOUP directly from one of the carousel storage bins positioned approximately at the top of the stocker 202. For example, the overhead transport vehicle 205 may extend a distance 222 (about 0.9 m) from the ceiling 214.

In an illustrative mode of operation, the selected carousel storage bin, e.g., the storage bin 203 containing the FOUP 210, is positioned approximately at the top of the vertical carousel stocker 202 underneath the track 208. The overhead transport vehicle 205 is then moved along the track 208 to a position substantially directly above the storage bin 203. Next, the overhead hoist is lowered from the overhead transport vehicle 205 through the opening in the stocker housing 252 toward the storage bin 203. For example, the overhead hoist may be lowered in a direction parallel to the longitudinal axis L₁ of the stocker. The overhead hoist is then operated to pick the FOUP 210 directly from the storage bin 203 for subsequent transport to a workstation or processing machine on the IC chip manufacturing floor. It is understood that the overhead hoist may alternatively be operated to place a FOUP in the carousel storage bin 203.
Fig. 3 depicts an alternative embodiment 300 of the AMHS 200 (see Fig. 2). As shown in Fig. 3, the AMHS 300 comprises an overhead hoist transport system 304, and at least one vertical carousel WIP stocker 302 including a plurality of storage bins such as a slide-mounted storage bin 332. Like the vertical carousel stocker 202, the vertical carousel stocker 302 is configured to allow an overhead hoist in the overhead hoist transport system 304 to access WIP parts, e.g., semiconductor wafers, directly from a selected one of the carousel storage bins.

Specifically, the AMHS 300 may be employed in an IC chip manufacturing environment including a ceiling 314, a waffle slab 320, and a raised floor 326 located above the waffle slab 320. As shown in Fig. 3, the vertical carousel stocker 302 is positioned on the waffle slab 320. For example, the raised floor 326 may be located a distance 328 (about 0.6 m) above the waffle slab 320 and a distance 324 (greater than about 5.4 m) below the ceiling 314. Further, the vertical carousel stocker 302 includes a housing 352, and first and second pulleys 350-351 and a belt 354 disposed within the housing 352. The carousel storage bins (e.g., the slide-mounted storage bin 332) are coupleable to the belt 354 at various spaced locations along the belt, and the belt 354 is looped between the first and second pulleys 350-351 to allow the storage bins to be rotatably positioned along the belt path by driving one of the pulleys 350-351. For example, the vertical carousel stocker 302 may have a height 318 (about 6 m).

As described above, the vertical carousel stocker 302 is configured to allow an overhead hoist to access the semiconductor wafers directly from one of the carousel storage bins. In the illustrated embodiment, at least one side of the housing 352 is at least partially open to allow the selected carousel storage bin to be extracted from within the housing 352, and to allow
subsequent top-loading/unloading of the selected storage bin by
the overhead hoist. Specifically, the AMHS 300 further includes
at least one extraction mechanism 330, which works to extract the
semiconductor wafers from within the stocker 302, and to suitably
position the material relative to a suspended track 308 included
in the overhead hoist transport subsystem 304. It is noted that
each storage bin may comprise either a movable or fixed shelf.
Further, the semiconductor wafers are loaded into cassette pods
such as a FOUP 310 disposed on the shelf 332.

The overhead hoist transport subsystem 304 includes the
suspended track 308 and at least one overhead hoist transport
vehicle 305 configured to travel on the track 308. The track 308
defines at least one predetermined route passing parallel to the
vertical carousel stocker 302, thereby allowing the overhead
transport vehicle 305 to access a FOUP directly from a selected
one of the slide-mounted storage bins.

In an illustrative mode of operation, the selected slide-
mounted storage bin, e.g., the storage bin 332 containing the
FOUP 310, is positioned to allow the extraction mechanism 330 to
extract the storage bin 332 from within the stocker 302 and to
position the storage bin 332 directly underneath the track 308.
It is noted that the extraction mechanism 330 may be incorporated
into the stocker 302 and configured to move the storage bin 332
along a single servo-controlled axis 398. The overhead transport
vehicle 305 is then moved along the track 308 to a position
directly above the extracted storage bin 332. Next, the overhead
hoist is lowered from the overhead transport vehicle 305 toward
the storage bin 332, e.g., in a direction parallel to the
longitudinal axis L2 of the stocker. The overhead hoist is then
operated to pick the FOUP 310 directly from the storage bin 332
for subsequent transport to a workstation or processing machine
on the IC chip manufacturing floor. It is appreciated that the
overhead hoist may alternatively be operated to place a FOUP in the carousel storage bin 332.

Fig. 4 depicts a detailed embodiment 400 of the AMHS 300 (see Fig. 3). In the illustrated embodiment, the AMHS 400 comprises an overhead hoist transport system 404 and a vertical carousel stocker 402. The overhead hoist transport system 404 includes a suspended track 408 and an overhead hoist transport vehicle 405 configured for traveling on the track 408. For example, the overhead transport vehicle 405 may extend a distance 436 (about 0.9 m) from the track 408. The vertical carousel stocker 402 includes a plurality of carousel storage bins such as a storage bin 432 disposed within the stocker housing. For example, the storage bin 432 may be a distance 438 (about 2.6 m) above the raised IC chip manufacturing floor.

As described above, a FOUP 410 is extracted from within the stocker housing to allow subsequent top-loading/unloading of the selected storage bin. The overhead transport vehicle 405 further includes an overhead hoist 431 having a gripper configured to top-load/unload the FOUP 410 to/from the storage bin 432. In the preferred embodiment, the hoist gripper 430 is mounted on a translating stage to allow the overhead hoist to pick/place a cassette pod to either side of the overhead transport vehicle 405.

Figs. 5a-5b depict a translating hoist vehicle subsystem 704 accessing fixed storage positions. In the illustrated embodiment, the translating hoist vehicle subsystem 704 includes a suspended track 708, and an overhead hoist transport vehicle 705 configured to travel on the track. The overhead transport vehicle 705 is configured to pick/place a FOUP 710 to a fixed storage position 732. For example, the overhead transport vehicle 705 may extend a distance 736 (about 0.9 m) below the ceiling 714, and the storage position 732 may be disposed a
distance 738 (about 2.6 m) above the raised IC chip manufacturing floor. Further, the ceiling 714 may be a distance 790 (about 3.66 m) above the raised floor.

The overhead transport vehicle 705 is configured to pick (and place) the FOUP 710 to a position located directly below the suspended track 708. To that end, the overhead hoist vehicle 705 includes a hoist gripper 731 mounted to a translating stage and configured to extend from the vehicle 705, pick up the FOUP 710, and retract back to the vehicle 705, thereby moving the FOUP 710 within the overhead transport vehicle 705 (see Fig. 5b). In the preferred embodiment, the translating stage is configured to allow the overhead hoist to pick/place a cassette pod to either side of the overhead transport vehicle 705. Once the FOUP 710 is held by the hoist gripper 730, the overhead transport vehicle 705 transports it to a workstation or processing machine on the IC chip manufacturing floor.

Fig. 6 depicts a translating hoist vehicle system 800 accessing material either stored or moving on a conveyer 895. Specifically, an overhead hoist transport subsystem 804 is employed to directly pick or place a FOUP 810 to the overhead rail-based conveyer 895. In the illustrated embodiment, the overhead hoist transport subsystem 804 includes a suspended track 808 and an overhead hoist transport vehicle 805 configured to travel on the track 808. For example, the overhead transport vehicle 805 may extend a distance 836 (about 0.9 m) below the track 808 and be disposed a distance 892 (about 0.35 m) above the rail-based conveyer 895. Further, the overhead rail 898 may be a distance 838 (about 2.6 m) above the raised IC manufacturing floor. It should be understood that the rail 898 extends in a direction perpendicular to the plane of the drawing. The translating hoist vehicle system 800 further includes a process tool load port 899.
The overhead transport vehicle 805 may be employed to perform top-loading/unloading of the rail-based conveyer 895. To that end, the overhead transport vehicle 805 includes an overhead hoist 831 having a hoist gripper 835, which is mounted to a translating stage 833 configured to allow both horizontal and vertical motion, as indicated by the directional arrows 870 and 871, respectively. In an illustrative mode of operation, the rail-based conveyer 895 is moved so that the FOUP 810 is positioned directly underneath the overhead hoist 831. The hoist gripper 835 is then lowered via the translating stage 833 toward the FOUP 810, and operated to pick the FOUP 810 directly from the conveyer 895. Next, the hoist gripper 835 carrying the FOUP 810 is raised and retracted via the translating stage 833, thereby moving the FOUP 810 within the overhead transport vehicle 805. The transport vehicle 805 then transports the FOUP 810 to a workstation or processing machine on the IC chip manufacturing floor.

A method of operating the presently disclosed automated material handling system is illustrated by reference to Fig. 7. As depicted in step 902, a selected storage bin containing a FOUP is positioned within a vertical carousel stocker to allow access by an overhead hoist. For example, the selected carousel storage bin may be positioned at the top or at the side of the vertical carousel stocker (see Figs. 2-3). Next, the overhead hoist transport vehicle is moved along a track, as depicted in step 904, to a position adjacent the selected storage bin. In the event the selected storage bin is positioned at the top of the stocker, the overhead transport vehicle is positioned above the storage bin. In the event the selected storage bin is positioned at the side of the stocker, the overhead transport vehicle is positioned to the side of the storage bin. The overhead hoist is then extended from the transport vehicle and lowered, as depicted
in step 906, to allow the hoist gripper to contact the FOUP in the selected storage bin. Next, the hoist gripper is operated, as depicted in step 908, to pick the FOUP directly from the storage bin. The overhead hoist is then raised and retracted, as depicted in step 910, to move the FOUP within the overhead transport vehicle. In this way, the FOUP is top-loaded from the selected storage bin to the overhead transport vehicle. Finally, the overhead transport vehicle transports, as depicted in step 912, the FOUP to a workstation or processing machine on the product manufacturing floor.

It will further be appreciated by those of ordinary skill in the art that modifications to and variations of the above-described automated material handling system may be made without departing from the inventive concepts disclosed herein. Accordingly, the invention should not be viewed as limited except as by the scope and spirit of the appended claims.
CLAIMS

What is claimed is:

1. An automated material handling system, comprising:
   at least one storage unit including a plurality of storage bins, each storage bin being configured to hold at least one unit of material; and
   an overhead hoist transport subsystem including at least one overhead hoist, the overhead hoist being configured to access at least one material unit directly from a selected one of the plurality of storage bins for subsequent transport to a predetermined location.

2. The system of claim 1 wherein the overhead hoist is further configured to provide at least one material unit directly to the selected storage bin for subsequent storage within the storage unit.

3. The system of claim 1 wherein the selected material unit is moved directly to the overhead hoist by moving to a position external to the storage unit.

4. The system of claim 3 wherein the storage unit further includes a mechanism configured to move the material unit in at least one axial direction.

5. The system of claim 1 wherein the selected storage bin comprises a fixed shelf disposed within the storage unit.

6. The system of claim 5 wherein the overhead hoist transport subsystem includes a translating stage coupled to the overhead hoist, the translating stage being configured to move the overhead hoist.
hoist to a first position to allow the hoist to access the at least one material unit directly from the fixed shelf.

7. The system of claim 6 wherein the translating stage is further configured to move the overhead hoist to a second position to allow the hoist to remove the at least one material unit from the storage unit.

8. The system of claim 1 wherein the at least one storage unit comprises a vertical carousel stocker.

9. The system of claim 8 wherein the vertical carousel stocker is configured to move the selected storage bin to an upper region of the stocker to allow the overhead hoist to access the at least one material unit from a position above the selected storage bin.

10. The system of claim 9 wherein the overhead hoist transport subsystem further includes a track and a vehicle for transporting the overhead hoist configured to travel on the track, at least a portion of the track being disposed substantially directly above the selected storage bin at the upper region of the stocker.

11. The system of claim 8 wherein the vertical carousel stocker is configured to move the selected storage bin to a first position along one side of the stocker to allow the overhead hoist to access the at least one material unit from a second position alongside the selected storage bin.

12. The system of claim 11 wherein the overhead hoist transport subsystem further includes a track and a vehicle for transporting the overhead hoist configured to travel on the track, at least a portion of the track being disposed substantially parallel to a
longitudinal axis of the stocker adjacent the first position alongside the stocker.

13. The system of claim 1 wherein the overhead hoist includes a gripper portion configured to grip the at least one material unit.

14. The system of claim 1 wherein the material unit comprises a cassette pod.

15. A method of operating an automated material handling system, comprising the steps of:
   - holding at least one unit of material by a selected one of a plurality of storage bins included in a material storage unit;
   - accessing the at least one material unit directly from the selected storage bin by an overhead hoist included in an overhead hoist transport subsystem; and
   - transporting the at least one material unit to a predetermined location by the overhead hoist transport subsystem.

16. The method of claim 15 further including the step of providing at least one material unit directly to the selected storage bin by the overhead hoist for subsequent storage within the storage unit.

17. The method of claim 15 further including the step of providing the at least one material unit directly to the overhead hoist by the selected storage bin, the selected storage bin comprising a movable shelf.

18. The method of claim 17 further including the step of moving the shelf in at least one axial direction by a mechanism included in the storage unit.
19. The method of claim 15 further including the step of moving the overhead hoist to a first position by a translating stage to allow the hoist to access the at least one material unit directly from the selected storage bin, the selected storage bin comprising a fixed shelf.

20. The method of claim 19 further including the step of moving the overhead hoist to a second position by the translating stage to allow the hoist to remove the at least one material unit from the storage unit.

21. The method of claim 15 further including the step of moving the selected storage bin to an upper region of the storage unit by a carousel mechanism included in the storage unit, thereby allowing the overhead hoist to access the at least one material unit from a position above the selected storage bin.

22. The method of claim 21 further including the step of transporting the overhead hoist by a vehicle traveling on a track, the overhead hoist transport vehicle and the track being included in the overhead hoist transport subsystem, wherein at least a portion of the track is disposed substantially directly above the selected storage bin at the upper region of the storage unit.

23. The method of claim 15 further including the step of moving the selected storage bin to a first position along one side of the storage unit by a carousel mechanism included in the storage unit, thereby allowing the overhead hoist to access the at least one material unit from a second position alongside the selected storage bin.
24. The method of claim 23 further including the step of transporting the overhead hoist by a vehicle traveling on a track, the overhead hoist transport vehicle and the track being included in the overhead hoist transport subsystem, wherein at least a portion of the track is disposed substantially parallel to a longitudinal axis of the storage unit adjacent the first position alongside the storage unit.

25. The method of claim 15 further including the step of gripping the at least one material unit by a gripper portion of the overhead hoist.

26. The method of claim 25 further including the step of gripping the at least one material unit by the gripper portion of the overhead hoist, wherein the material unit comprises a cassette pod.
FIG. 7

Start

Position selected carousel storage bin to allow access by overhead hoist

Move overhead hoist transport vehicle to position adjacent the selected storage bin

Extend and lower overhead hoist to allow hoist gripper to contact FOUP

Operate hoist gripper to pick FOUP directly from selected storage bin

Raise and retract hoist to move FOUP within overhead transport vehicle

Transport FOUP to workstation/processing machine

End
**INTERNATIONAL SEARCH REPORT**

**A. CLASSIFICATION OF SUBJECT MATTER**

IPC(7) : G06F 7/00  
US CL : 700/213, 218

According to International Patent Classification (IPC) or to both national classification and IPC.

**B. FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 700/213, 218

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

**C. DOCUMENTS CONSIDERED TO BE RELEVANT**

<table>

<td>US 4,979,360 A (KALLMANN et al.) 25 December 1990, entire document</td>
<td>1-26</td>
</tr>
</tbody>
</table>

☐ Further documents are listed in the continuation of Box C.  
☐ See patent family annex.

* Special categories of cited documents:
- **A** document defining the general state of the art which is not considered to be of particular relevance.

- **B** earlier application or patent published on or after the international filing date.

- **L** document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified).

- **D** document referred to in an oral disclosure, use, exhibition or other means.

- **P** document published prior to the international filing date but later than the priority date claimed.

- **T** later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention.

- **X** document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone.

- **Y** document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

- **S** document member of the same patent family.

Date of the actual completion of the international search: 19 June 2003 (19.06.2003)

Date of receipt of this international search report: 22 Aug 2003
