(54) Title: SHEAR FORCE DETECTION USING CAPACITIVE SENSORS

(57) Abstract: An input device having a sensing region overlapping an input surface includes a first substrate, a second substrate physically coupled to the first substrate, and a sensor electrode disposed on the first substrate and configured to detect input objects in the sensing region. A first force sensor includes a first electrode disposed on the first substrate and a first conductive portion of the second substrate capacitively coupled with the first electrode. The first conductive portion is configured to move relative to the first electrode such that a first variable capacitance of the first force sensor changes in response to force applied to the input surface in a first direction parallel to the touch surface.

SHEAR FORCE DETECTION USING CAPACITIVE SENSORS

PRIORITY INFORMATION

[0001] This application claims priority to United States Non-Provisional Patent Application Serial No. 13/827,138, which was filed on March 14, 2013 and is incorporated herein by reference.

FIELD OF THE INVENTION

[0002] This invention generally relates to electronic devices, and more particularly to input devices configured to detect shear forces.

BACKGROUND OF THE INVENTION

[0003] Input devices including proximity sensor devices (also commonly called touchpads or touch sensor devices) are widely used in a variety of electronic systems. A proximity sensor device typically includes a sensing region, often demarked by a surface, in which the proximity sensor device determines the presence, location and/or motion of one or more input objects. Proximity sensor devices may be used to provide interfaces for the electronic system. For example, proximity sensor devices are often used as input devices for larger computing systems (such as opaque touchpads integrated in, or peripheral to, notebook or desktop computers). Proximity sensor devices are also often used in smaller computing systems (such as touch screens integrated in cellular phones).

[0004] The proximity sensor device can be used to enable control of an associated electronic system. For example, proximity sensor devices are often used as input devices for larger computing systems, including: notebook computers and desktop computers. Proximity sensor devices are also often used in smaller systems, including: handheld systems such as personal digital assistants (PDAs), remote controls, and communication systems such as wireless telephones and text messaging systems. Increasingly, proximity sensor devices are used in media systems, such as CD, DVD, MP3, video or other media recorders or players. The proximity sensor device can be integral or peripheral to the computing system with which it interacts.

[0005] Presently known proximity sensors have the ability to detect and determine force applied to a surface of the sensor, for example, by providing one or more force sensors coupled to the surface of the sensor, such as strain gauge load cells, piezoelectric crystal force transducers, and the like. It is also known to estimate applied force by measuring the increased capacitance resulting from the increased contact area when a finger is pressed against the surface. Drawbacks associated with estimating applied force using these techniques include limited accuracy and complex construction. Consequently, such sensors have are limited in their ability to use such determined force as a basis for determining user input. This limits the flexibility of the proximity sensor device to function as an input device. Thus, there exists a need for improvements in proximity sensor devices, and in particular, in the ability of proximity sensor devices to determine and respond to indications of applied force.

[0006] Other desirable features and characteristics will become apparent from the subsequent detailed description and the appended claims, taken in conjunction with the accompanying drawings and the foregoing technical field and background.

BRIEF SUMMARY OF THE INVENTION

[0007] Devices and methods are provided that facilitate improved input device performance. An input device utilizes at least one sensor electrode disposed on a first substrate to sense input objects in a sensing region of the device. The first substrate is physically coupled to a second substrate and configured to translate in response to a force applied to the input surface. A plurality of force sensor electrodes are disposed on the first substrate such that they overlap conductive portions of the second substrate and form variable capacitances with the conductive portions. A force applied to the input surface resulting in a translation of the first substrate relative to the second substrate changes the distance between (and/or the area of overlap between) the plurality of force sensor electrodes and the conductive portions of the second substrate. Each force sensor of the plurality of force sensors may be configured to measure a normal and/or planar translation of the first substrate relative to the second substrate.

[0008] Input devices according to the present invention exhibit an improved ability to determine the tangential, normal and/or rotational components of force applied to the

surface of the sensor. A measurement of the variety of forces applied to the input surface may be used to provide increased input functionality for the user.

BRIEF DESCRIPTION OF DRAWINGS

[0009] The preferred exemplary embodiment of the present invention will hereinafter be described in conjunction with the appended drawings, where like designations denote like elements, and:

[0010] FIG. 1 is a block diagram of an exemplary system that includes an input device in accordance with an embodiment of the invention;

[0011] FIG. 2 illustrates a top and a profile view of an input device in accordance with an embodiment of the invention;

[0012] FIG. 3 illustrates a top and a profile view of an input device in accordance with an embodiment of the invention;

[0013] FIGS. 4A and 4B illustrate respective a top views of an input device in accordance with an embodiment of the invention;

[0014] FIGS. 5A – 5D illustrate respective top views of an input device in accordance with an embodiment of the invention;

[0015] FIGS 6A – 6F illustrate various alternate embodiments of force sensors configured to detect deflection of the first substrate relative to the second substrate in accordance with an embodiment of the invention; and

[0016] FIG. 7 illustrates multiple embodiments of a second substrate and the arrangement of a conductive portion on the second substrate in accordance with an embodiment of the invention.

DETAILED DESCRIPTION OF THE INVENTION

[0017] The following detailed description is merely exemplary in nature and is not intended to limit the invention or the application and uses of the invention. Furthermore, there is no intention to be bound by any expressed or implied theory presented in the preceding technical field, background, brief summary or the following detailed description.

[0018] Various embodiments of the present invention provide input devices and methods that facilitate improved usability.

[0019] Turning now to the figures, FIG. 1 is a block diagram of an exemplary input device 100, in accordance with embodiments of the invention, which combines a proximity sensor with a plurality of force sensors. The input device 100 uses both the proximity sensor and the force sensors to provide an interface for the electronic system. As used in this document, the term “electronic system” (or “electronic device”) broadly refers to any system capable of electronically processing information. Some non-limiting examples of electronic systems include personal computers of all sizes and shapes, such as desktop computers, laptop computers, netbook computers, tablets, web browsers, e-book readers, and personal digital assistants (PDAs). Additional example electronic systems include composite input devices, such as physical keyboards that include input device 100 and separate joysticks or key switches. Further example electronic systems include peripherals such as data input devices (including remote controls and mice), and data output devices (including display screens and printers). Other examples include remote terminals, kiosks, and video game machines (e.g., video game consoles, portable gaming devices, and the like). Other examples include communication devices (including cellular phones, such as smart phones), and media devices (including recorders, editors, and players such as televisions, set-top boxes, music players, digital photo frames, and digital cameras). Additionally, the electronic system could be a host or a slave to the input device.

[0020] The input device 100 can be implemented as a physical part of the electronic system, or can be physically separate from the electronic system. As appropriate, the input device 100 may communicate with parts of the electronic system using any one or more of the following: buses, networks, and other wired or wireless interconnections. Examples include I²C, SPI, PS/2, Universal Serial Bus (USB), Bluetooth, RF, and IRDA.

[0021] In FIG. 1, the input device 100 is shown as a proximity sensor device (also often referred to as a “touchpad” or a “touch sensor device”) configured to sense input provided by one or more input objects 140 in a sensing region 120. Example input objects include fingers and styli, as shown in FIG. 1. The input device 100 has a processing system 110, a sensing region 120 having an input surface 118, and four force sensors 150 implemented proximate the sensing region. As will be described in greater detail below, each of the force sensors 150 may be implemented with any of the various embodiments of force sensors described below. Furthermore, it should be noted that while the force sensors 150 are illustrated as being outside the input surface 118, in other embodiments one or more force sensors may be provided within the perimeter of the input surface 118. Likewise, it should be noted that while FIG. 1 shows four force sensors 150 disposed near the corners of the input surface 118, that in other embodiments described below, more or fewer force sensors may be provided and may be disposed on various arrangements with respect to the input surface 118. Not shown in FIG. 1 is an array of sensing electrodes that are adapted to capacitively sense objects in the sensing region 120.

[0022] The input device 100 is adapted to provide user interface functionality by facilitating data entry responsive to sensed input objects and the force applied by such objects. Specifically, the processing system 110 is configured to determine positional information for objects interacting with the sensing region 120. This positional information can then be used by the electronic system to provide a wide range of user interface functionality.

[0023] Furthermore, the processing system 110 is configured to determine force information for input objects from measures of force determined by the force sensors 150. This force information can then also be used by the electronic system to provide a wide range of user interface functionality. For example, by providing different user interface functions in response to different levels/direction of applied force by input objects in the sensing region.

[0024] Sensing region 120 encompasses any space above, around, in and/or near the input device 100 in which the input device 100 is able to detect user input (e.g., user input provided by one or more input objects 140). The sizes, shapes, and locations of particular sensing regions may vary widely from embodiment to embodiment. In some embodiments,

the sensing region 120 extends from a surface of the input device 100 in one or more directions into space until signal-to-noise ratios prevent sufficiently accurate object detection. The distance to which this sensing region 120 extends in a particular direction, in various embodiments, may be on the order of less than a millimeter, millimeters, centimeters, or more, and may vary significantly with the type of sensing technology used and the accuracy desired. Thus, some embodiments sense input that comprises no contact with any surfaces of the input device 100, contact with an input surface (e.g. a touch surface) of the input device 100, contact with an input surface of the input device 100 coupled with some amount of applied force or pressure, and/or a combination thereof. In various embodiments, input surfaces may be provided by surfaces of casings within which the sensor electrodes reside, by face sheets applied over the sensor electrodes or any casings, etc. In some embodiments, the sensing region 120 has a rectangular shape when projected onto an input surface of the input device 100.

[0025] The input device 100 may utilize any combination of sensor components and sensing technologies to detect user input in the sensing region 120. The input device 100 comprises one or more sensing elements for detecting user input. As several non-limiting examples, the input device 100 may use capacitive, elastive, resistive, inductive, magnetic, acoustic, ultrasonic, and/or optical techniques. Some implementations are configured to provide images that span one, two, three, or higher dimensional spaces. Some implementations are configured to provide projections of input along particular axes or planes.

[0026] In some resistive implementations of the input device 100, a flexible and conductive first layer is separated by one or more spacer elements from a conductive second layer. During operation, one or more voltage gradients are created across the layers. Pressing the flexible first layer may deflect it sufficiently to create electrical contact between the layers, resulting in voltage outputs reflective of the point(s) of contact between the layers. These voltage outputs may be used to determine positional information.

[0027] In some inductive implementations of the input device 100, one or more sensing elements pick up loop currents induced by a resonating coil or pair of coils. Some combination of the magnitude, phase, and frequency of the currents may then be used to determine positional information.

[0028] In some capacitive implementations of the input device 100, voltage or current is applied to create an electric field. Nearby input objects cause changes in the electric field, and produce detectable changes in capacitive coupling that may be detected as changes in voltage, current, or the like.

[0029] Some capacitive implementations utilize arrays or other regular or irregular patterns of capacitive sensing elements to create electric fields. In some capacitive implementations, separate sensing elements may be ohmically shorted together to form larger sensor electrodes. Some capacitive implementations utilize resistive sheets, which may be uniformly resistive.

[0030] Some capacitive implementations utilize “self capacitance” (or “absolute capacitance”) sensing methods based on changes in the capacitive coupling between sensor electrodes and an input object. In various embodiments, an input object near the sensor electrodes alters the electric field near the sensor electrodes, thus changing the measured capacitive coupling. In one implementation, an absolute capacitance sensing method operates by modulating sensor electrodes with respect to a reference voltage (e.g. system ground), and by detecting the capacitive coupling between the sensor electrodes and input objects.

[0031] Some capacitive implementations utilize “mutual capacitance” (or “transcapacitance”) sensing methods based on changes in the capacitive coupling between sensor electrodes. In various embodiments, an input object near the sensor electrodes alters the electric field between the sensor electrodes, thus changing the measured capacitive coupling. In one implementation, a transcapacitive sensing method operates by detecting the capacitive coupling between one or more transmitter sensor electrodes (also “transmitter electrodes” or “transmitters”) and one or more receiver sensor electrodes (also “receiver electrodes” or “receivers”). Transmitter sensor electrodes may be modulated relative to a reference voltage (e.g., system ground) to transmit transmitter signals. Receiver sensor electrodes may be held substantially constant relative to the reference voltage to facilitate receipt of resulting signals. A resulting signal may comprise effect(s) corresponding to one or more transmitter signals, and/or to one or more sources of environmental interference (e.g. other electromagnetic signals). Sensor electrodes may be dedicated transmitters or receivers, or may be configured to both transmit and receive.

[0032] In FIG. 1, a processing system 110 is shown as part of the input device 100. The processing system 110 is configured to operate the hardware of the input device 100 to detect input in the sensing region 120. The processing system 110 comprises parts of or all of one or more integrated circuits (ICs) and/or other circuitry components. For example, a processing system for a mutual capacitance sensor device may comprise transmitter circuitry configured to transmit signals with transmitter sensor electrodes, and/or receiver circuitry configured to receive signals with receiver sensor electrodes). In some embodiments, the processing system 110 also comprises electronically-readable instructions, such as firmware code, software code, and/or the like. In some embodiments, components composing the processing system 110 are located together, such as near sensing element(s) of the input device 100. In other embodiments, components of processing system 110 are physically separate with one or more components close to sensing element(s) of input device 100, and one or more components elsewhere. For example, the input device 100 may be a peripheral coupled to a desktop computer, and the processing system 110 may comprise software configured to run on a central processing unit of the desktop computer and one or more ICs (perhaps with associated firmware) separate from the central processing unit. As another example, the input device 100 may be physically integrated in a phone, and the processing system 110 may comprise circuits and firmware that are part of a main processor of the phone. In some embodiments, the processing system 110 is dedicated to implementing the input device 100. In other embodiments, the processing system 110 also performs other functions, such as operating display screens, driving haptic actuators, etc.

[0033] The processing system 110 may be implemented as a set of modules that handle different functions of the processing system 110. Each module may comprise circuitry that is a part of the processing system 110, firmware, software, or a combination thereof. In various embodiments, different combinations of modules may be used. Example modules include hardware operation modules for operating hardware such as sensor electrodes and display screens, data processing modules for processing data such as sensor signals and positional information, and reporting modules for reporting information. Further example modules include sensor operation modules configured to operate sensing element(s) to detect input, identification modules configured to identify gestures such as mode changing gestures, and mode changing modules for changing operation modes.

[0034] In some embodiments, the processing system 110 responds to user input (or lack of user input) in the sensing region 120 directly by causing one or more actions. Example actions include changing operation modes, as well as GUI actions such as cursor movement, selection, menu navigation, and other functions. In some embodiments, the processing system 110 provides information about the input (or lack of input) to some part of the electronic system (e.g. to a central processing system of the electronic system that is separate from the processing system 110, if such a separate central processing system exists). In some embodiments, some part of the electronic system processes information received from the processing system 110 to act on user input, such as to facilitate a full range of actions, including mode changing actions and GUI actions.

[0035] For example, in some embodiments, the processing system 110 operates the sensing element(s) of the input device 100 to produce electrical signals indicative of input (or lack of input) in the sensing region 120. The processing system 110 may perform any appropriate amount of processing on the electrical signals in producing the information provided to the electronic system. For example, the processing system 110 may digitize analog electrical signals obtained from the sensor electrodes. As another example, the processing system 110 may perform filtering or other signal conditioning. As yet another example, the processing system 110 may subtract or otherwise account for a baseline, such that the information reflects a difference between the electrical signals and the baseline. As yet further examples, the processing system 110 may determine positional information, recognize inputs as commands, recognize handwriting, and the like.

[0036] “Positional information” as used herein broadly encompasses absolute position, relative position, velocity, acceleration, and other types of spatial information. Exemplary “zero-dimensional” positional information includes near/far or contact/no contact information. Exemplary “one-dimensional” positional information includes positions along an axis. Exemplary “two-dimensional” positional information includes motions in a plane. Exemplary “three-dimensional” positional information includes instantaneous or average velocities in space. Further examples include other representations of spatial information. Historical data regarding one or more types of positional information may also be determined and/or stored, including, for example, historical data that tracks position, motion, or instantaneous velocity over time.

[0037] Likewise, the term “force information” as used herein is intended to broadly encompass force information regardless of format. For example, the force information can be provided for each object as a vector or scalar quantity. Specifically, force information may comprise normal, tangential and rotational force applied to the input surface. As another example, the force information can be provided as an indication that determined force has or has not crossed a threshold amount. As other examples, the force information can also include time history components used for gesture recognition. As will be described in greater detail below, positional information and force information from the processing systems may be used to facilitate a full range of interface inputs, including use of the proximity sensor device as a pointing device for selection, cursor control, scrolling, GUI navigation and other functions.

[0038] In some embodiments, the input device 100 is implemented with additional input components that are operated by the processing system 110 or by some other processing system. These additional input components may provide redundant functionality for input in the sensing region 120, or some other functionality. While not shown in FIG. 1, buttons near the sensing region 120 that can be used to facilitate selection of items using the input device 100. Other types of additional input components include sliders, balls, wheels, switches, and the like. Conversely, in some embodiments, the input device 100 may be implemented with no other input components.

[0039] In some embodiments, the input device 100 comprises a touch screen interface, and the sensing region 120 overlaps at least part of an active area of a display screen. For example, the input device 100 may comprise substantially transparent sensor electrodes overlaying the display screen and provide a touch screen interface for the associated electronic system. The display screen may be any type of dynamic display capable of displaying a visual interface to a user, and may include any type of light emitting diode (LED), organic LED (OLED), cathode ray tube (CRT), liquid crystal display (LCD), plasma, electroluminescence (EL), or other display technology. The input device 100 and the display screen may share physical elements. For example, some embodiments may utilize some of the same electrical components for displaying and sensing. As another example, the display screen may be operated in part or in total by the processing system 110.

[0040] It should be understood that while many embodiments of the invention are described in the context of a fully functioning apparatus, the mechanisms of the present invention are capable of being distributed as a program product (e.g., software) in a variety of forms. For example, the mechanisms of the present invention may be implemented and distributed as a software program on information bearing media that are readable by electronic processors (e.g., non-transitory computer-readable and/or recordable/writable information bearing media readable by the processing system 110). Additionally, the embodiments of the present invention apply equally regardless of the particular type of medium used to carry out the distribution. Examples of non-transitory, electronically readable media include various discs, memory sticks, memory cards, memory modules, and the like. Electronically readable media may be based on flash, optical, magnetic, holographic, or any other storage technology.

[0041] As noted above, the input device 100 may be implemented with a variety of different types and arrangements of capacitive sensing electrodes. To name several examples, the capacitive sensing device may be implemented with electrode arrays that are formed on multiple substrate layers, including parts of the same layers used to form the force sensors. As one specific embodiment, electrodes for sensing in one direction (e.g., the “X” direction) may be formed on a first layer (e.g., on a first side of a first substrate or any other suitable substrate), while the electrodes for sensing in a second direction (e.g., the “Y” direction) are formed on a second layer (e.g., on another side of the first substrate or any other suitable substrate).

[0042] In other embodiments, the electrodes for both the X and Y sensing may be formed on the same layer, with that same layer comprising any of the substrates described in below. In yet other embodiments, the electrodes may be arranged for sensing in only one direction, e.g., in either the X or the Y direction. In still another embodiment, the electrodes may be arranged to provide positional information in polar coordinates, such as “r” and “ θ ” as one example. In these embodiments the electrodes themselves are commonly arranged in a circle or other looped shape to provide “ θ ”, with the shapes of individual electrodes used to provide “r”. Also, a variety of different electrode shapes may be used, including electrodes shaped as thin lines, rectangles, diamonds, wedge, etc. Finally, a variety of conductive materials and fabrication techniques may be used to form the electrodes. As one example, the electrodes are formed by the deposition and etching of copper or ITO on a substrate.

[0043] Turning now to FIG. 2, top and profile views of input device 200 are illustrated. The input device is implemented with a first substrate 241, a second substrate 242 and two force sensors 250-1 and 250-2. The first substrate 241 is physically coupled to the second substrate 242 and configured to move relative to the second substrate 242 in response to a force applied to an input surface 220. The input device is also configured to sense input objects in a sensing region (sensing region not shown), for example, using capacitive sensing electrodes disposed on the first substrate 242.

[0044] The first substrate 241 is configured to move relative to the second substrate 242 in multiple directions and/or dimensions. A force applied to the input surface 220 can move the first substrate 241 in a first direction having a component along arrow 262, and in a second direction having a component along arrow 264. For example, movement of the first substrate 241 relative to the second substrate 242 in a first direction 262 occurs in response to a force applied in a first direction parallel to the input surface 220. Likewise, a force applied in a second direction parallel to the input surface 220 results in movement of the first substrate 241 in a second direction 264. A force applied to the input surface 220 which has a force component directed along both the first and second directions will result in a combination of movement along both the first and second directions 262 and 264. Furthermore, a force applied in a direction perpendicular to the input surface 220 results in a movement of the first substrate 241 in an orthogonal direction 260 with respect to the second substrate 242.

[0045] In the illustrated embodiment, the first and second substrates are physically coupled via springs 290. However, this is just one example of a coupling mechanism which may be used to allow the first substrate 241 to move relative to substrate 242 in the first and/or second directions 262 and 264. Various methods for coupling the first and second substrate, which allow for movement in the first and/or second directions, are possible and contemplated by the present disclosure. For example, the first and second substrate may be physically coupled with an adhesive or a mechanical linkage.

[0046] In the embodiment of FIG. 2, first and second force sensors 250-1 and 250-2 are shown. Force sensor 250-1 includes a first force sensor electrode 251, and force sensor 250-2 includes a first force sensor electrode 252, both first force sensor electrodes being disposed on the first substrate 241. Force sensors 250-1 and 250-2 also include a conductive portion of the second substrate, illustrated as items 256 and 257, which are capacitively

coupled to the first force sensor electrode 251 and second force sensor electrode 252, respectively. Thus, the first force sensor electrode 251 and the first conductive portion 256 form a first variable capacitance (not shown), and the second force sensor electrode 252 and the second conductive portion 257 form a second variable capacitance (not shown).

[0047] Movement of the first substrate 241, in response to a force applied to the input surface 220, results in a change of at least one of the first and second variable capacitances 256 and 257. A measurement of the changes in the variable capacitances is used to determine the force applied to the input surface 220. For example, movement of the first substrate 241 relative to the second substrate 242 in a first direction 262 changes the first and second variable capacitances 256 and 257 differently based on the direction of movement along the first direction 262. Movement in an upwards direction along the first direction 262 will increase the variable capacitance of the first force sensor 250-1 and decrease the variable capacitance of the second force sensor 250-2. Conversely, movement in a downwards direction along the first direction 262 will decrease the variable capacitance of the first force sensor 250-1 and increase the variable capacitance of the second force sensor 250-2.

[0048] The change in the variable capacitances is determined, in part, by a change in the distance and/or area of overlap between the force sensor electrodes and the conductive portions of each force sensor 250-1 and 250-2. A measurement of the variable capacitance(s) of each force sensor can thus be used to determine force information for the object(s) applying force to the input surface 220. In some implementations, a variable capacitance of a force sensor can have a relatively linear response to force. That is, as force is applied to the input surface resulting in movement of the first substrate 241 relative to the second substrate 242, the resulting change in capacitance is a function of the amount of relative movement between first substrate 241 and the second substrate 242. Likewise, the amount of movement may also be a function of the force applied to the input surface 220. With the appropriate selection of materials and geometries for the force sensors 250-1 and 250-2, the input device 200 may provide an accurate and useful measure of applied force. A more detailed example is described in the embodiment of FIG. 3.

[0049] As will be described in greater detail below, a measurement of the variable capacitance formed by each force sensor may comprise an absolute or “self-capacitive” measurement. In such an embodiment, a force sensor electrode is modulated with respect to

a reference voltage and a change in capacitive coupling between the force sensor electrode and a conductive object (e.g. a conductive portion such as variable capacitances 256 and 257) is indicative of the movement of the force sensor electrode relative to the conductive object. In other embodiments, a measurement of the variable capacitance formed by each force sensor may comprise a mutual capacitance or “trans-capacitive” measurement. In such an embodiment, at least two force sensor electrodes of a force sensor form a capacitive coupling between each other and the presence of a conductive object (e.g. a conductive portion like 256 and 257) can change the magnitude of the capacitive coupling.

[0050] In various embodiments of the present invention a force sensor comprises a conductive portion disposed on a second substrate (e.g., conductive portions 256 and 257 in FIG. 2) which at least partially overlaps the force sensor electrodes of each force sensor. A displacement and/or translation of the conductive portion of each force sensor changes (i) an area of overlap and/or (ii) a spacing between the force sensor electrodes and the conductive portion. As will be described in greater detail with reference to FIG. 7, a conductive portion affixed to a non-conductive second substrate may be functionally equivalent to a non-conductive portion of a conductive second substrate. For example, with reference to FIG. 2, in another embodiment the second substrate 242 may be conductive and “conductive portions” 256 and 257 may be non-conductive. Such an arrangement is functionally equivalent for the purposes of force sensing, since the change in capacitive coupling between the force sensor electrode(s) disposed on the first substrate and a conductive material on the second substrate is functionally equivalent to the coupling to a conductive second substrate having a non-conductive portion at least partially overlapping the force sensor electrodes.

[0051] Turning now to FIG. 3, top and profile views of input device 300 are illustrated. The input device is implemented with a first substrate 341 coupled to and moveable relative to a second substrate 342. A force applied to the input surface 320 can move the first substrate 341 in a first direction 362, a second direction 364 and/or a third direction 360. Specifically, a normal force component applied to the input surface 320 will result in movement along the third direction 360 and a tangential force component applied to the input surface 320 will result in movement along the first and/or second direction 362 and 364.

[0052] The input device 300 is also implemented with four force sensors 350-1, 350-2, 350-3 and 350-4. Each force sensor comprises a first force sensor electrode which is capacitively coupled to a first conductive portion of the second substrate. This is illustrated in FIG. 3 for the first force sensor 350-1 which comprises a first sensor electrode 351-1 capacitively coupled to a first conductive portion 356-1 of the second substrate 342. Also, an area of overlap 353-1 between the first sensor electrode 351-1 and the first conductive portion 356-1 is shown. For clarity of illustration, force sensors 350-2, 350-3 and 350-4 have a similar arrangement which is not specifically enumerated in FIG. 3.

[0053] A variable capacitance of each force sensor can be measured based on the movement of the first substrate relative to the second substrate, the distance separating a force sensor electrode from a conductive portion, and the area of overlap between a force sensor electrode and a conductive portion. In the embodiment of FIG. 3, the first and second substrates are separated by a distance “ d ” and a dielectric (e.g., air). For simplicity, each force sensing electrode and conductive portion are taken to be square, and the area of overlap (as exemplified by the area of overlap 353-1) is thus: $A=l*l=l^2$. The capacitive coupling between each force sensor electrode and conductive portion may be modeled by Equations 1a-d as:

$$(Eq. 1a) \quad C_{350-1}(\delta_x, \delta_y, \delta_z) \approx \frac{\epsilon(A + l(-\delta_x + \delta_y))}{d - \delta_z}$$

$$(Eq. 1b) \quad C_{350-2}(\delta_x, \delta_y, \delta_z) \approx \frac{\epsilon(A + l(\delta_x + \delta_y))}{d - \delta_z}$$

$$(Eq. 1c) \quad C_{350-3}(\delta_x, \delta_y, \delta_z) \approx \frac{\epsilon(A + l(-\delta_x - \delta_y))}{d - \delta_z}$$

$$(Eq. 1d) \quad C_{350-4}(\delta_x, \delta_y, \delta_z) \approx \frac{\epsilon(A + l(\delta_x - \delta_y))}{d - \delta_z}$$

where movement of the first substrate along the first direction 362 is defined as δ_y , movement along the second direction 364 is defined as δ_x , and movement along the third direction 360 is defined as δ_z . The capacitive coupling varies in response to displacements in the first, second and/or third directions (362, 364, 360). If the second order term of $\delta_y * \delta_x$ is ignored, the variable capacitances may be modeled by Equations 2a-d as:

$$\text{(Eq. 2a)} \quad \Delta C_{350-1}(\delta_x, \delta_y, \delta_z) \approx \frac{\varepsilon}{d - \delta_z} \left(A \frac{\delta_z}{d} + l(-\delta_x + \delta_y) \right) \approx \frac{\varepsilon}{d} \left(A \frac{\delta_z}{d} + l(-\delta_x + \delta_y) \right)$$

$$\text{(Eq. 2b)} \quad \Delta C_{350-2}(\delta_x, \delta_y, \delta_z) \approx \frac{\varepsilon}{d - \delta_z} \left(A \frac{\delta_z}{d} + l(\delta_x + \delta_y) \right) \approx \frac{\varepsilon}{d} \left(A \frac{\delta_z}{d} + l(\delta_x + \delta_y) \right)$$

$$\text{(Eq. 2c)} \quad \Delta C_{350-3}(\delta_x, \delta_y, \delta_z) \approx \frac{\varepsilon}{d - \delta_z} \left(A \frac{\delta_z}{d} + l(-\delta_x - \delta_y) \right) \approx \frac{\varepsilon}{d} \left(A \frac{\delta_z}{d} + l(-\delta_x - \delta_y) \right)$$

$$\text{(Eq. 2d)} \quad \Delta C_{350-4}(\delta_x, \delta_y, \delta_z) \approx \frac{\varepsilon}{d - \delta_z} \left(A \frac{\delta_z}{d} + l(\delta_x - \delta_y) \right) \approx \frac{\varepsilon}{d} \left(A \frac{\delta_z}{d} + l(\delta_x - \delta_y) \right)$$

Equations 2a-d can be written in matrix form as Equation 3:

$$\text{(Eq. 3)} \quad \Delta C = \frac{\varepsilon}{d} \begin{bmatrix} -l & l & \frac{A}{d} \\ l & l & \frac{A}{d} \\ -l & -l & \frac{A}{d} \\ l & -l & \frac{A}{d} \end{bmatrix} \begin{bmatrix} \delta_x \\ \delta_y \\ \delta_z \end{bmatrix} \equiv M \begin{bmatrix} \delta_x \\ \delta_y \\ \delta_z \end{bmatrix}$$

The matrix M of Equation 3 is full rank, allowing a determination of the movement of the first substrate 341 relative to the second substrate 342 by computing:

$$\text{(Eq. 4)} \quad \begin{bmatrix} \delta_x \\ \delta_y \\ \delta_z \end{bmatrix} = (M^T M)^{-1} M^T \Delta C$$

[0054] Thus, a measurement of the variable capacitances of the force sensors 350-1, 350-2, 350-3 and 350-4 can be used to determine the displacement of the first substrate 341 relative to the second substrate 342. Based on the determined displacement and mechanical properties of the attachment mechanism which couples the first and second substrate together, the force applied to the input surface 320 may be determined. In some embodiments, positional information for input objects contacting the input surface 320 may be determined by capacitive sensor electrodes (not shown) disposed on the first substrate 341. The capacitive sensor electrodes may be also used to determine the force applied to the input surface 320. In some embodiments, force information for each input object applying a

force to the input surface may be separately determined; that is, force may be determined on a per input object basis.

[0055] The force sensors discussed in connection with FIG. 2 and FIG. 3 enable detection of the force applied to the input surface of the input device based on a change in a variable capacitance of the force sensors. Specifically, movement of the first substrate relative to the second substrate results in: (i) a change in the area of overlap between a force sensor electrode and a conductive portion; and/or (ii) a change in the distance between a force sensor electrode and a conductive portion. Scenarios (i) and (ii) will change the variable capacitance of each of the force sensors. By appropriately configuring the force sensor electrodes, “positive” or “negative” displacements in the first, second and/or third direction (362, 364, 360) may be determined. Specifically, the force sensors shown in FIG. 3 are designed to be sensitive (i.e. vary in a capacitive coupling) to “positive” or “negative” displacement along the first and second directions 362 and 364. For simplicity, displacement along the third direction 360 can be considered to be unidirectional, since any displacement of the first substrate 341 from a default/resting position will necessarily occur “downwardly” in a positive direction along the third direction 360.

[0056] Table 1 summarizes the variable capacitance behavior of each force sensor of the input device 300 in response to five degrees of motion (i.e., five types of independent motion) :

<i>Displacement direction</i>	<i>Force Sensor 350-1</i>	<i>Force Sensor 350-2</i>	<i>Force Sensor 350-3</i>	<i>Force Sensor 350-4</i>
(+) δ_z	+	+	+	+
(+) δ_x	-	+	-	+
(-) δ_x	+	-	+	-
(+) δ_y	+	+	-	-
(-) δ_y	-	-	+	+

Table 1: Force Sensor behavior due to displacement

Thus, the combined measurements from all the force sensors may be used to determine the magnitude of displacement (i.e. force) of the first substrate as well as the direction of the displacement, as determined by the arrangement of the force sensor electrode with respect to the conductive portions of each force sensor.

[0057] Turning now to FIG. 4A, a top view of an input device 400A is illustrated. The input device 400 is similar in construction to input devices 200 and 300 of FIGS. 2 and 3. The input device 400A comprises a first substrate 441 coupled to a second substrate 442. The first substrate 441 includes an input surface (not shown) and is configured to move in a planar direction relative to the second substrate 442 (i.e., vertical “z” displacement is not contemplated). The input device 400A also includes a plurality of force sensors 450-1, 450-2, 450-3 and 450-4. Each force sensor comprises a first force sensor electrode disposed on the first substrate 441 which forms a variable capacitance with a first conductive portion of the second substrate 442. For example, force sensor 450-1 comprises force sensor electrode 451-1 which is capacitively coupled to conductive portion 456-1. Force sensors 450-2, 450-3 and 450-4 comprise analogous components of force sensor electrodes and conductive portions which are not enumerated for purposes of clarity.

[0058] The force sensors 450-1, 450-2, 450-3 and 450-4 shown in FIG. 4A differ from force sensors 250-X and 350-X shown in FIG. 2 and FIG. 3, respectively. When a non-normal (non-orthogonal) force is applied to the input surface of input device 400A, resulting in movement of the first substrate 441 relative to the second substrate 442 in a first and/or second direction 462 and 464, force sensors 450-1, 450-2, 450-3 and 450-4 are configured such that a variable capacitance associated with each of the force sensors remains substantially constant in response to movement in one of the first direction 462 and the second direction 464. Specifically, with reference to force sensor 450-1, the area of overlap between the first force sensor electrode 451-1 and the first conductive portion 456-1, enumerated as area of overlap 453-1, does not change in response to motion of the first substrate 441 in a first direction 462. Consequently, the variable capacitance of force sensor 450-1 does not significantly change in response to motion in the first direction. Similarly, the variable capacitance of force sensor 450-3 does not change in response to motion of the first substrate 441 in the second direction 464.

[0059] In one embodiment, an input object applying a force to the input surface results in motion of the first substrate 441 in only the first and/or second direction 462 and 464

(vertical and rotational motion is not present). Measurement of the variable capacitances of two force sensors, such as force sensors 450-1 and 450-3, can be used to determine the displacement of the first substrate 441 in both the first and second directions 462 and 464. Based on the determined displacement, a measurement of the force applied to the input surface can be determined. By arranging the force sensor electrodes in particular configurations, “positive” or “negative” displacements in the first and/or second direction (462, 464) may be determined. Specifically, the force sensors 450-1 and 450-3 shown in FIG. 4 exhibit sensitivity (i.e. vary in a capacitive coupling) to “positive” or “negative” displacement along the first and second directions 462 and 464 from a neutral or “default” position of the first substrate relative to the second substrate.

[0060] In another embodiment, an input object applying a force to the input surface results in motion of the first substrate 441 in a first direction 462, a second direction 464, and a rotation of the first substrate 441 relative to the second substrate 442, enumerated as motion direction 466. In such an embodiment, the first substrate 441 is configured to rotate relative to the second substrate 442 in response to a non-normal force applied to the input surface of input device 400A. For example, the first substrate 441 is configured to rotate about an axis (perpendicular to the plane of FIG. 4A) passing through point 467 which is at the center of the input surface. The location of the point 467 and the axis of rotation may be anywhere on the input surface, or even outside of the input surface. The location of point 467 is determined by the attachment mechanism which couples the first and second substrates. A measurement of the rotational displacement of the first substrate 441 may be determined by at least one of the force sensors 450-1 and 450-3. The clockwise (“positive”) or counterclockwise (“negative”) rotation of the first substrate 441 is determined by the change in the variable capacitance of at least one of the force sensors 450-1 and 450-3.

[0061] Table 2 summarizes the variable capacitance response of force sensors 450-1 and 450-3 in response to motion of the first substrate 441 in the first direction 462 (δ_x), the second direction 464 (δ_y) and rotational directions 466 (δ_θ) in response to the six different types of independent motion.

<i>Displacement direction</i>	<i>Force Sensor 450-1</i>	<i>Force Sensor 450-3</i>
(+) δ_x	-	Constant

$(-) \delta_x$	+	Constant
$(+) \delta_y$	Constant	-
$(-) \delta_y$	Constant	+
$(+) \delta_\theta$	-	-
$(-) \delta_\theta$	+	+

Table 2: Force Sensor 450-1 and 450-3 response due to displacement

Thus, the combined measurements from the force sensors 450-1 and 450-3 may be used to determine both the magnitude of the displacement (i.e. force) of the first substrate, and the direction of the displacement. This is a function of the arrangement of the force sensor electrode with respect to the conductive portions of each force sensor.

[0062] While the embodiments discussed above with respect to FIG. 4A include two force sensors to determine different types of motions of the first substrate 441 in response to a force applied to the input surface, in some cases the combinatorial (i.e., combined or aggregate) movement in all three directions (462, 464 and 466) results in a combination of measurements where the specific displacements along each of the directions is not readily discernible. While it should be appreciated that the first force sensor 450-1 is immune to effects of movement in the first direction 462 and the second force sensor 450-3 is immune to effects of movement in the second direction 464, neither force sensor is immune to movement in the rotational direction 466. Furthermore, each force sensor 450-1 and 450-3 is sensitive to clockwise ($+\delta_\theta$) and counter clockwise ($-\delta_\theta$) motion in the same manner (i.e. both sensors have the same change in their variable capacitance (+ or -)) in response to motion in either of the directions. A straightforward approach to this problem involves the addition of one more force sensors. For example, in an embodiment including force sensors 450-1, 450-2 and 450-3, the capacitive response (i.e. the change in the variable capacitances of the force sensors) may be summarized as set forth in Table 3:

<i>Displacement direction</i>	<i>Force Sensor 450-1</i>	<i>Force Sensor 450-2</i>	<i>Force Sensor 450-3</i>
$(+) \delta_x$	-	+	Constant

$(-) \delta_x$	+	-	Constant
$(+) \delta_y$	Constant	Constant	-
$(-) \delta_y$	Constant	Constant	+
$(+) \delta_\theta$	-	-	-
$(-) \delta_\theta$	+	+	+

Table 3: Force Sensor 450-1, 450-2 and 450-3 response due to displacement

The use of a third force sensor 450-2 enables the determination of combinatorial movement of the first substrate 441 along all three directions (462, 464, and 466) without any limitations.

[0063] As discussed above with reference to FIG. 3, a variable capacitance associated with each force sensor can be measured based on the movement of the first substrate relative to the second substrate, the distance separating each force sensor electrode from each conductive portion, and the area of overlap between the each force sensor electrode and each conductive portion. With reference to FIG. 4A, unlike FIG. 3, the variable capacitances of force sensors 450-1, 450-2, 450-3 and 450-4 remains substantially constant in response to at least one type of motion, the types of motion comprising the first and second direction 462 and 464.

[0064] In one embodiment, as described above with reference to FIG 4A, an input object applying a force to the input surface results in lateral motion of the first substrate 441 in only the first and/or second direction 462 and 464 (vertical and rotational motion is not present). In this example, $S_{450-1}, S_{450-2}, S_{450-3}, S_{450-4}$ represent the measurements of the variable capacitance of the four force sensors 450-1, 450-2, 450-3 and 450-4, respectively. The displacement of the first substrate 441 relative to the second substrate 442 in the first and second directions 462 and 464 can be modeled by Eq. 5a-b:

$$(Eq. 5a) \quad \delta_x \approx k(S_{450-1} - S_{450-2})$$

$$(Eq. 5b) \quad \delta_y \approx k(S_{450-3} - S_{450-4})$$

wherein the constant k is determined by the mechanical properties of the attachment mechanism coupling the first and second substrates 441 and 442 together. Note that second

order effects may be ignored for simplicity and the displacement of the first substrate 441 is relatively small compared to the size of the first substrate.

[0065] In another embodiment, as described above with reference to FIG. 4A, a force applied to the input surface results in motion of the first substrate 441 in a first direction 462 and a second direction 464, and a rotation of the first substrate 441 relative to the second substrate 442 (vertical motion is not present) represented as rotational motion 466. The displacement of the first substrate 441 in the rotational direction 466 can be modeled by Eq. 5c:

$$(Eq. 5c) \quad \delta_{\theta} \approx k(S_{450-1} + S_{450-2} + S_{450-3} + S_{450-4})$$

For simplicity, Eq. 5c assumes that the axis of rotation defined by point 467 is located at the geometric center of the input surface of the first substrate 441 and that the force sensors 450-1, 450-2, 450-3 and 450-4 are symmetrically located about the point 467. Analogous computational techniques can be used for other geometries, where the rotation of the first substrate 441 is not about the center of the substrate and/or the force sensors are not symmetrically placed about the geometric center of rotation.

[0066] In the embodiments of FIG. 4A described above, vertical motion of the first substrate 441 relative to the second substrate 442 was not involved. In other words, a normal force applied to the input surface did not move the first substrate 441 closer to the second substrate 442, and thus did not change the distance between a force sensor electrode and conductive portion in any of the force sensors described. If such a motion was present, the capacitive behavior of each of the force sensors would also be subject to the vertical displacement of the first substrate 441. As a result, the combinatorial movement in all three directions (462, 464 and 466) along with a vertical displacement (not enumerated but analogous to vertical directions 260 and 360) results in a combination of measurements where the specific displacements along each of the directions is not able to be determined.

[0067] Turning now to FIG. 4B, an embodiment is described which further allows for a normal force applied to the input surface of the first substrate 441 to result in a vertical displacement towards the second substrate 442. The input device 400B shown in FIG. 4B is similar to the input device of FIG. 4A and only additional features are enumerated for simplicity. The input device 400B is configured to allow movement of the first substrate 441 relative to the second substrate 442 in a direction perpendicular to the input surface

(analogous to input surface 220/320 and perpendicular motion 260/360). The perpendicular (i.e., vertical) motion of the input surface and the first substrate 441 relative to the second substrate 442 results in a change the variable capacitances of force sensors 450-1, 450-2, 450-3 and 450-4. As mentioned above with respect to FIG. 4A, the variable capacitance of each of the force sensors remains substantially constant in response to movement in one of the first direction 462 and the second direction 464, and in the embodiment of FIG. 4B, the variable capacitances exhibited by force sensors 450-1, 450-2, 450-3 and 450-4 also change in response to motion in a vertical direction. In other embodiments described below, force sensors may be implemented which form at least one variable capacitance which does not change in response to vertical motion are described.

[0068] The input device 400B further comprises four force sensors 450-5, 450-6, 450-7 and 450-8 which are configured such that a variable capacitance of each of the force sensors remains substantially constant in response to movement in the first direction 462 and the second direction 464. In other words, force sensors 450-5, 450-6, 450-7 and 450-8 are only sensitive to vertical motion of the first substrate relative to the second substrate. Specifically, with reference to force sensor 450-5, the area of overlap between the first force sensor electrode 451-5 and the first conductive portion 456-5 of the second substrate 442 does not change due to lateral and/or rotational motion of the first substrate 441. Table 4 summarizes the capacitive response (i.e. the change in the variable capacitance of the force sensors) of input device 400B shown in FIG. 4B:

<i>Displacement direction</i>	<i>Force Sensor 450-1</i>	<i>Force Sensor 450-2</i>	<i>Force Sensor 450-3</i>	<i>Force Sensor 450-4</i>	<i>Force Sensor 450-5</i>	<i>Force Sensor 450-6</i>	<i>Force Sensor 450-7</i>	<i>Force Sensor 450-8</i>
(+) δ_x	-	+	Constant	Constant	Constant	Constant	Constant	Constant
(-) δ_x	+	-	Constant	Constant	Constant	Constant	Constant	Constant
(+) δ_y	Constant	Constant	-	+	Constant	Constant	Constant	Constant
(-) δ_y	Constant	Constant	+	-	Constant	Constant	Constant	Constant
(+) δ_θ	-	-	-	-	Constant	Constant	Constant	Constant
(-) δ_θ	+	+	+	+	Constant	Constant	Constant	Constant

(+) δ_z	+	+	+	+	+	+	+	+
----------------	---	---	---	---	---	---	---	---

Table 4: Force Sensor behavior due to displacement of input device 400B

[0069] In this example, $Z_{450-5}, Z_{450-6}, Z_{450-7}, Z_{450-8}$ represent the measurements of the variable capacitance of the four force sensors 450-5, 450-6, 450-7 and 450-8, respectively. The measurements of the variable capacitance of the four force sensors 450-1, 450-2, 450-3 and 450-4 ($S_{450-1}, S_{450-2}, S_{450-3}, S_{450-4}$) depend on lateral and vertical motion of the first substrate relative 441 to the second substrate 442 and can be described as:

$$\begin{aligned}
 \tilde{S}_{450-1} &= S_{450-1} + f_{450-1}(S_{450-1}, Z_{450-5}, Z_{450-6}, Z_{450-7}, Z_{450-8}) \\
 \tilde{S}_{450-2} &= S_{450-2} + f_{450-2}(S_{450-4}, Z_{450-5}, Z_{450-6}, Z_{450-7}, Z_{450-8}) \\
 \tilde{S}_{450-3} &= S_{450-3} + f_{450-3}(S_{450-3}, Z_{450-5}, Z_{450-6}, Z_{450-7}, Z_{450-8}) \\
 \tilde{S}_{450-4} &= S_{450-4} + f_{450-4}(S_{450-4}, Z_{450-5}, Z_{450-6}, Z_{450-7}, Z_{450-8})
 \end{aligned}
 \tag{Eq. 6a}$$

If the force applied to the input surface does not result in any vertical motion of the first substrate 441 relative to the second substrate 442, then:

$$\text{(Eq. 6b)} \quad \tilde{S}_{450-3} = S_{450-3}, \quad \tilde{S}_{450-4} = S_{450-4}, \quad \tilde{S}_{450-2} = S_{450-2}, \quad \tilde{S}_{450-1} = S_{450-1}$$

since:

$$\begin{aligned}
 \text{(Eq. 6c)} \quad f_L(S_L, 0, 0, 0, 0) &= 0 & f_R(S_R, 0, 0, 0, 0) &= 0 \\
 f_T(S_T, 0, 0, 0, 0) &= 0 & f_B(S_B, 0, 0, 0, 0) &= 0
 \end{aligned}$$

[0070] Furthermore, if the mechanical model of the deflection of the first substrate 441 relative to the second substrate is purely linear, then $f_L(0, Z_{TL}, Z_{TR}, Z_{BL}, Z_{BR})$, $f_R(0, Z_{TL}, Z_{TR}, Z_{BL}, Z_{BR})$, $f_T(0, Z_{TL}, Z_{TR}, Z_{BL}, Z_{BR})$, and $f_B(0, Z_{TL}, Z_{TR}, Z_{BL}, Z_{BR})$ will be a linear combination of the four force sensors 450-5, 450-6, 450-7 and 450-8. Thus, in the presence of vertical deflection, displacement of the first substrate relative to the second substrate in all three directions (462, 464, and 466) can be determined using Eq. 5a-c.

[0071] In the embodiment described above in FIG. 4B, the vertical motion of the first substrate is assumed to be non-uniform. In other words, the change in distance between the first and second substrate in response to a force applied in a perpendicular direction to the input surface is not substantially equal across the input surface. Force applied to the input surface in a perpendicular direction and in the geometric center of the input surface may

result in uniform vertical deflection; while the same force applied in a corner of the input surface may result in a substantially different amount of vertical deflection as measured, for example, at different locations across the input surface. The mechanical properties of the input device and attachment mechanism between the first substrate the second substrate determine not only the directions in which the first substrate is configured to move, but also the type of motion allowed. For example, in various embodiments, the input device may be configured to allow lateral motion, rotational motion, and/or vertical motion (uniform and non-uniform). It should be understood, given descriptions of the embodiments above, that the type, number and arrangements of force sensors configured to measure the deflection of the first substrate relative to the second substrate should be selected based on the type of motion allowed in response to forces imparted on the input surface of the input device.

[0072] FIGS. 5A-5D show various embodiments of the input device having different arrangements of force sensors configured to detect motion of the first substrate relative to the second substrate. The arrangement and type of force sensors used in the configurations shown depend on the type of the input surface the input device is configured for. For example, in the embodiment of FIG. 5A, the input device allows: (i) non-uniform vertical translation; (ii) lateral motion in a first and second direction; and (iii) rotational motion in response to a force applied to the input surface. The input device comprises eight force sensors. Four of the eight force sensors are “Z-sensors”, which are immune to lateral or rotational motion (i.e., they are only able to sense vertical motion). The other four force sensors are “shear sensors”, at least one of which is immune to lateral motion in one direction and at least one other is immune to lateral motion in a second direction. Furthermore, each of the four “shear sensors” is sensitive to rotational motion. The arrangement and type of force sensors used in FIG. 5A enable a measurement and determination of the amount of deflection in directions (i)-(iii) and the force imparted to the input surface which causes the deflection of the input surface.

[0073] In another example, in the embodiment of FIG. 5B, the input device allows (i) non-uniform vertical translation and (ii) lateral motion in a first and second direction. The input device comprises eight force sensors. Four of the eight force sensors are “Z-sensors”, which are immune to lateral or rotational motion (i.e., they are only able to sense vertical motion). The other four force sensors are “shear sensors”, wherein at least one is immune to lateral motion in one direction and at least one other is immune to lateral motion in a second direction. All of the force sensors of the input device are immune to rotation of the first

substrate about its center relative to the second substrate. The arrangement and type of force sensors used in FIG. 5B enable a measurement and determination of the amount of deflection in directions (i)-(ii) and the force imparted on the input surface causing the deflection of the input surface.

[0074] In another example, in the embodiment of FIG. 5C, the input device allows for (i) uniform vertical translation and (ii) lateral motion in a first and second direction and (iii) rotational motion in response to a force applied to the input surface. The input device comprises five force sensors. One of the force sensors is a “Z-sensor” which is immune to lateral or rotational motion (able to only sense vertical motion). Since the vertical translation of the first substrate relative to the second substrate is uniform, one “Z” force sensor is able to determine a change in the variable capacitances of any of the other force sensors due to a vertical displacement. Four of the force sensors are “shear” sensors, wherein at least one is immune to lateral motion in one direction and at least one other is immune to lateral motion in a second direction. The arrangement and type of force sensors used in FIG. 5C enable a measurement and determination of the amount of deflection in directions (i)-(iii) and the force imparted on the input surface causing the deflection of the input surface.

[0075] In yet another example, in the embodiment of FIG. 5D, the input device allows: (i) uniform vertical translation, (ii) lateral motion in a first and second direction, and (iii) rotational motion in response to a force applied to the input surface. The input device comprises five force sensors. One of the force sensors is a “Z-sensor” which is immune to lateral or rotational motion (able to only sense vertical motion). Since the vertical translation of the first substrate relative to the second substrate is uniform, one “Z” force sensor is able to determine a change in the variable capacitances of any of the other force sensors due to a vertical displacement. Four of the force sensors are “shear” sensors, wherein at least one is immune to lateral motion in one direction and at least one other is immune to lateral motion in a second direction. The arrangement and type of force sensors used in FIG. 5D enable a measurement and determination of the amount of deflection in directions (i)-(iii) and the force imparted on the input surface causing the deflection of the input surface.

[0076] In the various embodiments described with reference to FIGS. 1-5, a variable capacitance associated with each force sensor may be used to determine an amount of

deflection and/or translation of a first substrate relative to a second substrate. Similarly, the variable capacitance of each force sensor may be used to determine the force applied to an input surface of the input device. In the embodiments described in FIGS. 1-5, each force sensor includes a first force sensor electrode disposed on the first substrate and a conductive portion disposed on the second substrate. FIG. 6 shows various alternate embodiments of force sensors configured to detect deflection of the first substrate relative to the second substrate.

[0077] Turning to FIG. 6A-F, a plurality of embodiments for a force sensor which can be used by the input device to determine deflection and/or translation of a first substrate relative to a second substrate are shown. For example, the force sensor 610 of FIG. 6A-B comprises a first force sensor electrode 611, a second force sensor electrode 612, and a conductive area 614. The force sensor 610 may be implemented as part of the input device described above wherein the first and second force sensor electrodes 611 and 612 are disposed on a first substrate and a second substrate comprises the conductive portion 614. A first variable capacitance of the force sensor 610 is formed between the first and second force sensor electrodes 611 and 612. In response to movement of the conductive portion 614, the first variable capacitance changes due to (i) a change in the distance between the first and second substrates (and thus the distance between the force sensor electrode 611 and 612 and the conductive portion 614) and/or (ii) a change in the area of overlap between the conductive portion 614 and the first and second force sensor electrodes 611 and 612.

[0078] In the embodiments of FIGS. 6A-B, the first variable capacitance may result from a transcapacitive coupling between the first and second force sensor electrode 611 and 612, wherein the first force sensor electrode 611 is configured to transmit a sensing signal and the second force sensor electrode 612 is configured to receive a resulting signal. The resulting signal received by force sensor electrode 612 comprises effects of the conductive portion 614 on the received resulting signal. For example, in FIG. 6A, under the assumption that the conductive portion will always overlap the force sensor electrodes in response to lateral motion of the first substrate relative to the second substrate, the force sensor 610 is essentially a vertical displacement sensor. In other words, the force sensor 610 is immune to lateral motion of the conductive portion 614. Conversely, the force sensor 620 of FIG. 6B which comprises similarly operating sensor electrodes as force sensor 610 is sensitive to lateral and vertical motion of the conductive portion 614 relative to sensor electrodes 611 and 612.

[0079] FIG. 6C shows another alternate embodiment for a force sensor. Force sensor 630 comprises a first, second, third and fourth force sensor electrodes (611-1, 611-2, 612-1, and 612-2) and a conductive portion 614. The first and third force sensor electrodes 611-1 and 612-1 form a first variable capacitance and the second and fourth force sensor electrodes form a second variable capacitance. The first and second variable capacitance values may correspond to a transcapacitive coupling between the pair of electrodes that varies based on the deflection and/or translation of the conductive portion 614 relative to the force sensor electrodes. The force sensor 630 is essentially a combination of force sensor 610 and 620 with a sharing of a single conductive portion 614.

[0080] FIG. 6D shows another alternate embodiment of a force sensor. Force sensor 640 is similar to force sensor 630 without one of the force sensor electrodes. The force sensor 640 comprises a first, second and third force sensor electrodes (611-1, 611-2 and 612-1) and a conductive portion 614. The first and third force sensor electrodes 611-1 and 612-1 form a first variable capacitance and the second and third force sensor electrodes 611-1 and 612-1 form a second variable capacitance. Specifically, the third force sensor electrode 612-1 is configured to transmit a sensor signal, and the first and second force sensor electrodes 611-1 and 611-2 are each configured to receive a respective resulting signal. The resulting signals received by force sensor electrodes 611-1 and 611-2 represent a first and second variable capacitance, respectively. Movement of the conductive portion 614 relative to the first, second and third force sensor electrodes may change the variable capacitances. Specifically, vertical motion between the conductive portion and the force sensing electrodes will change the first and second variable capacitance, while lateral motion will only change the second variable capacitance (since the area of overlap of distance between the first and third force sensor electrodes 611-1 and 612-1 and the conductive portion does not change).

[0081] FIG. 6E shows another alternate embodiment of a force sensor. Force sensor 650 comprises a first force sensor electrode 611-1 which substantially surrounds a second force sensor electrode 612-2 which substantially surrounds a third force sensor electrode 611-1. A conductive portion 614 overlaps at least part of each of the first, second and third force sensor electrodes. The conductive portion 614 comprises an interior non-conductive region. In response to lateral movement of the conductive portion 614 and its interior non-conductive region relative to the first, second and third force sensor electrodes, the area of overlap between at least one of the force sensor electrodes and the conductive portion varies. In one embodiment, the second force sensor electrode 612-1 is configured to transmit a

sensing signal and the first and third force sensor electrodes 611-1 and 611-2 are each configured to receive a resulting signal indicative of a variable capacitance, namely, a first variable capacitance formed between the first and second force sensor electrode and a second variable capacitance formed between the second and third force sensor electrode. A measurement of the change in the first and/or second variable capacitances can be used to determine the amount of vertical and/or lateral motion of a first substrate, where the force sensor electrodes are disposed on the first substrate, and a second substrate comprises the conductive portion.

[0082] FIG. 6F shows another embodiment of a force sensor in accordance with the invention. In one embodiment, force sensor 660 comprises four force sensor electrodes 611-1, 611-2, 611-3, and 611-4 disposed on a first substrate of the input device, and a conductive portion 614 disposed on a second substrate of the input device. Each of the four force sensor electrodes is configured to form a variable capacitance with the conductive portion 614. Specifically, each of the four force sensor electrodes is configured to form a variable capacitance with the conductive portion 614. In response to movement of the first substrate (comprising the force sensor electrodes) relative to the second substrate (comprising the conductive portion), the variable capacitance will change. A measurement of the change in variable capacitance of the force sensor may be used to determine the amount of deflection and/or translation of the first substrate relative to the second substrate.

[0083] In another embodiment, force sensor 660 comprises 8 force sensor electrodes (611-1, 611-1, 611-1, 611-1, 612-1, 612-2, 612-3, and 612-4) disposed on a first substrate of the input device, and a conductive portion 614 disposed on a second substrate of the input device. Each pair of force sensor electrodes (e.g. force sensor electrodes 611-1 and 611-2) is configured to form a variable capacitance which varies in response to movement of the conductive portion 614. Thus, four variable capacitances are formed in force sensor 660; and a measurement of the change in the first, second, third and/or fourth variable capacitances of force sensor 660 can be used to determine the amount of vertical and/or lateral motion of a first substrate, upon which the force sensor electrodes are disposed, with respect to a second substrate comprising the conductive portion.

[0084] In the various embodiments of the input device and force sensors described above, a force sensor includes a conductive portion which deflects and/or translates relative to the force sensor electrode(s) of the force sensor. The deflection and/or translation of this

conductive portion is dependent on the motion of the second substrate relative to the first substrate of the input device. FIG. 7 shows multiple embodiments of the second substrate 742 and the arrangement of the conductive portion on the second substrate 742. Specifically, FIG. 7 illustrates the functional equivalence (interchangeability) of a conductive portion being disposed on a non-conductive second substrate and a non-conductive portion being disposed on a conductive second substrate

[0085] FIG. 7 shows two different embodiments of an exemplary second substrate. In one embodiment, shown to the left of the broken hash line, is a second substrate 742 which is conductive. In another embodiment, shown to the right of the broken hash line, the second substrate 742 is non-conductive. While it is possible to have a second substrate with similar properties (e.g., half conductive and half non-conductive), FIG. 7 primarily illustrates the function and design of the second substrate in either embodiment. FIG. 7 also shows four force sensors (750-1, 750-2, 750-3, 750-4) in accordance with the embodiments of the force sensors described in FIGS. 2-6. Each force sensor comprises at least one force sensor electrode disposed on a first substrate (not shown for clarity, but analogous to the first substrates of FIGS. 2-6 (e.g. 241, 341, etc.)). The area of the at least one force electrode is shown as a dashed line in all four of the force sensors in FIG. 7. As described above, each force sensor of the input device is configured to form at least one variable capacitance with a conductive portion of the second substrate. The following description shows possible arrangements of this conductive portion.

[0086] In a first embodiment, a first force sensor 750-1 of FIG. 7 comprises at least one force sensor electrode 751-1, and the second substrate 742, which is conductive, comprises a non-conductive portion 754-1. In some embodiments, this non-conductive portion 754-1 may be an aperture in the second substrate or an insulator disposed on the second substrate. Thus, the first force sensor electrode 751-1 partially overlaps the non-conductive portion 754-1 and a conductive portion of the conductive substrate 742. In response to motion of the second substrate in a first direction (e.g. direction 764) relative to the first substrate (not shown) and the at least one force sensor electrode 751-1, the area of overlap between the at least one force sensor electrode 751-1 and the conductive portion of substrate 742 changes. This results in a change of the variable capacitance formed between the at least one force sensor electrode 751-1 and the conductive portion of the second substrate 742. Specifically, motion along the first direction 764 will result in a greater/lesser area of overlap between the non-conductive portion 754-1 of the second substrate 742 and, thus, a correspondingly

lesser/greater area of overlap between the conductive portion of the second substrate 742 and the at least one force sensor electrode 751-1. A measurement of the change in the variable capacitance may be used to determine the amount of lateral motion between the first substrate (not shown) and the second substrate 742.

[0087] In a second embodiment, a second force sensor 750-2 of FIG. 7 comprises at least one force sensor electrode 751-2, and the second substrate 742, which is conductive, comprises non-conductive portions 754-2. In some embodiments, the non-conductive portions 754-2 may be apertures in the second substrate or an insulator disposed on the second substrate. Thus, the second force sensor electrode 751-2 partially overlaps the non-conductive portions 754-2 and a conductive portion of the conductive substrate 742. In response to motion of the second substrate in a first direction (e.g. direction 764) relative to the first substrate (not shown) and the at least one force sensor electrode 751-2, the area of overlap between the at least one force sensor electrode 751-2 and the conductive portion of substrate 742 changes. This will result in a change of the variable capacitance formed between the at least one force sensor electrode 751-2 and the conductive portion of the second substrate 742.

[0088] In a third embodiment, a third force sensor 750-3 of FIG. 7 comprises at least one force sensor electrode 751-3 and a conductive portion 756-3 disposed on the non-conductive second substrate 742. Thus, the third force sensor electrode 751-3 partially overlaps the conductive portion 756-3 of the non-conductive substrate 742. In response to motion of the second substrate in a first direction (e.g. direction 764) relative to the first substrate (not shown) and the at least one force sensor electrode 751-3, the area of overlap between the at least one force sensor electrode 751-3 and the conductive portion 756-3 of second substrate 742 changes. This results in a change of the variable capacitance formed between the at least one force sensor electrode 751-3 and the conductive portion 756-3 of the second substrate 742. Specifically, motion along the first direction 764 results in a greater/lesser area of overlap between the conductive portion 756-3 of the second substrate 742 and the at least one force sensor electrode 751-3, changing the variable capacitance of force sensor 750-3. A measurement of the change in the variable capacitance may be used to determine the amount of lateral motion between the first substrate (not shown) and the second substrate 742.

[0089] In a fourth embodiment, a fourth force sensor 750-4 of FIG. 7 comprises at least one force sensor electrode 751-4 and a conductive portion 756-4 disposed on the non-conductive second substrate 742. Thus, the fourth force sensor electrode 751-4 partially overlaps the conductive portion 756-4 of the non-conductive substrate 742. In response to motion of the second substrate in a first direction (e.g. direction 764) relative to the first substrate (not shown) and the at least one force sensor electrode 751-4, the area of overlap between the at least one force sensor electrode 751-4 and the conductive portion 756-4 of second substrate 742 changes. This results in a change of the variable capacitance formed between the at least one force sensor electrode 751-4 and the conductive portion 756-4 of the second substrate 742. Specifically, motion along the first direction 764 results in a greater/lesser area of overlap between the conductive portion 756-3 of the second substrate 742 and the at least one force sensor electrode 751-4, changing the variable capacitance of force sensor 750-4. A measurement of the change in the variable capacitance may be used to determine the amount of lateral motion between the first substrate (not shown) and the second substrate 742.

[0090] In all embodiments discussed herein, a variety of different materials and techniques can be used to form the various electrodes. For example, the first, second, third and/or fourth electrodes can be formed using a variety of material deposition techniques. As other examples, conductive materials such as metals or conductive oxides may be sputtered or plated on the substrate and etched to leave behind the desired electrode pattern. In other examples, the electrode material can be printed directly on the substrate, for example, by screen printing. In yet another example the electrode material may be embedded directly into the corresponding substrate. Finally, in yet other embodiments, electrode structures may be formed separately and then attached to the appropriate substrate.

[0091] Furthermore, in various embodiments discussed herein, force sensor electrodes disposed on the first substrate are used to determine rotational and/or lateral forces applied to the input surface of the input device. In some embodiments described above, vertical forces imparted on the input surface of the input device do not impart any relative motion between the first substrate and the second substrate, likely due to the mechanical arrangement of the coupling mechanisms between the first and second substrates. Such an arrangement may be beneficial, since the space required for the vertical displacement allows for a thinner input device. However, the desire to measure the normal component of an

applied force to the input surface may be facilitated by the first substrate alone. For example, in one embodiment, the first substrate may comprise a first, second and third array of sensor electrodes, wherein the first and second arrays are used to determine positional information about input objects in the sensing region. The third array and at least one of the first and second arrays of sensor electrodes can be used to measure the normal force applied to the input surface. For example, the first substrate may comprise a pliable component including the first and second arrays of sensor electrodes and a compressible component separating the pliable component from the third array of sensor electrodes. In response to a force applied to the input surface, the pliable component may deflect towards the third array of sensor electrodes, causing a change in the capacitive coupling between at least one of the first and second arrays and the third array of sensor electrodes. A measurement of the change in the capacitive coupling can be used to determine a normal component of a force imparted on the input surface. The determined normal component may be complimented with the determined lateral and/or rotational components (as determined by the force sensor electrodes) to provide force information for input objects in the sensing region.

[0092] A variety of materials may be used for the various other substrates in the input device. Common substrate materials such as polyimide (sold under the name Kapton®), polyethylene terephthalate (PET), polycarbonate, fiberglass, polymethyl methacrylate, metals, plastic, glass, and others may be used. A variety of materials may be used to provide the electrodes in the input device. As specific examples, the various electrodes may be patterned using a conductive material, such as ITO (indium tin oxide), silver or carbon conductive ink, and copper. Further, any appropriate patterning process may be used in forming the electrode, including sputter deposition, printing, and etching.

[0093] A capacitive input device is thus provided which is configured to sense input objects in a sensing region. The capacitive input device includes a first substrate having an input surface overlapped by the sensing region and a second substrate physically coupled to the first substrate. The first substrate further includes at least one sensor electrode configured to capacitively detect an input object in the sensing region, a first sub-set of force sensor electrodes, and a second sub-set of force sensor electrodes. The second substrate includes at least one conductive portion which is configured to move laterally, with respect to the first substrate, in response to a lateral force applied to the input surface.

[0094] A processing system for the input device comprises a sensor module and a determination module. The sensor module of the processing system is configured to operate the at least one sensor electrode disposed on the first substrate to detect input objects in the sensing region of the input device. For example, the sensor module may be configured to perform absolute and/or trans-capacitive sensing using the at least one sensor electrode to sense input objects in the sensing region. The sensor module is further configured to perform absolute and/or trans-capacitive sensing using the plurality of force sensor electrodes disposed on the second substrate. In one embodiment, the sensor module is configured to transmit a transmitter signal using a first force sensor electrode from a first sub-set of the plurality of force sensor electrodes. The processing system is further configured to receive a resulting signal using a first force sensor electrode from a second sub-set of the plurality of force sensor electrodes.

[0095] The determination module of the processing system may be configured to determine a first force value based on a first resulting signal received on a first force sensor electrode of the second sub-set of the plurality of force sensor electrodes. The first resulting signal is based on a capacitive coupling between at least one force sensor electrode of the first sub-set, the first force sensor electrode of the second sub-set and a first conductive portion of the second substrate. The determination module is further configured to determine the first force value based on a change in the first resulting signal based on lateral motion of the first substrate relative to the second substrate in response to a lateral force applied to the input surface.

[0096] The determination module of the processing system may be further configured to determine a second force value based on a second resulting signal received on a second force sensor electrode of the second sub-set of the plurality of force sensor electrodes. The second resulting signal is based on a capacitive coupling between at least one force sensor electrode of the first sub-set, the second force sensor electrode of the second sub-set a second conductive portion of the second substrate. The determination module is further configured to determine the second force value based on a change in the second resulting signal based on a lateral motion of the first substrate relative to the second substrate in response to a force applied to the input surface.

[0097] The determination module of the processing system may be further configured to determine a lateral force applied to the input surface based on the first and second force values. The determination module may be further configured to determine positional information for input objects in the sensing region using the at least one sensor electrode and to determine force information for input objects in the sensing region based on the positional information, the first force value and the second force value.

[0098] In some embodiments, the determination module of the processing system may be further configured to determine a third force value based on a third resulting signal received on a third force sensor electrode of the second sub-set of force sensor electrodes. The third resulting signal is based on a capacitive coupling between at least one force sensor electrode of the first sub-set, the third force sensor electrode of the second sub-set and the second conductive portion of the second substrate. The determination module is further configured to determine the third force value based on a change in the third resulting signal based on a vertical motion of the first substrate relative to the second substrate in response to a force applied to the input surface.

[0099] The determination module may be configured to determine the lateral force applied to the input surface based on at least one of the first, second and third force values. In one embodiment, the determination module is configured to determine a lateral force components applied to the input surface in a first and second direction. The lateral force component in the first direction is based on the first and third force values. The lateral force component in the second direction is based on the second and third force values.

[00100] In some embodiments, the determination module is further configured to determine a third force value based on a third resulting signal received on a third force sensor electrode of the second sub-set of force sensor electrodes. The third resulting signal is based on a capacitive coupling between at least one sensor electrode of the first sub-set, the third force sensor electrode of the second sub-set and a third conductive portion of the second substrate. The determination module is further configured to determine the third force value based on a change in the third resulting signal based on a rotational motion of the first substrate relative to the second substrate in response to a force applied to the input surface.

[00101] In some embodiments, the processing system may be configured to enable a user interface action based on the determined force information. For example, the processing system may enable use of a GUI on a display based on the determined positional and force information. In some embodiments, the processing system may be configured to enable different interface actions in response to lateral, vertical and rotational forces applied to the input surface and/or different directions of the lateral and rotational forces. Thus, lateral force information may be used for panning, navigation and the like. Rotational force information can be used to rotate an interface element or to implement steering-like functionality. A variety of unique interface actions can be mapped to the dynamic or static measurements of lateral, rotational and/or vertical forces measured by the processing system.

[00102] Thus, the embodiments and examples set forth herein are presented to explain the present invention and its various applications and to enable those skilled in the art to make and use the invention. However, those skilled in the art will recognize that the foregoing description and examples have been presented for the purposes of illustration and example only. The description as set forth is not intended to be exhaustive or to limit the invention to the precise forms disclosed.

CLAIMS

1. An input device having a sensing region overlapping an input surface of the input device, the input device comprising:

a first substrate;

a second substrate physically coupled to the first substrate;

at least one sensor electrode disposed on the first substrate, the at least one sensor electrode configured to detect input objects in the sensing region;

a first force sensor comprising:

a first force sensor electrode disposed on the first substrate; and

a first conductive portion of the second substrate capacitively coupled with the first force sensor electrode, the first conductive portion configured to move relative to the first force sensor electrode such that a first variable capacitance of the first force sensor changes in response to force applied to the input surface in a first direction parallel to the touch surface; and

a second force sensor comprising:

a second force sensor electrode disposed on the first substrate; and

a second conductive portion of the second substrate capacitively coupled with the second force sensor electrode, the second conductive portion configured to move relative to the second force sensor electrode such that a second variable capacitance of the second force sensor changes in response to force applied to the input surface in a second direction different from the first direction and parallel to the input surface.

2. The input device of Claim 1, wherein force applied to the input surface in a direction perpendicular to the input surface moves the first force sensor electrode relative to the first conductive portion and the second force sensor electrode relative to the second conductive portion, and changes at least one of the first and second variable capacitances.

3. The input device of Claim 1, the first force sensor further comprising:

a first area of overlap between the first force sensor electrode and the first conductive portion, the first area of overlap configured to vary in response to a parallel relative motion between the first substrate and the second substrate.

4. The input device of Claim 3, the second force sensor further comprising:
a second area of overlap between the second force sensor electrode and the second conductive portion, the second area of overlap configured to remain substantially constant in response to the parallel relative motion between the first substrate and the second substrate..

5. The input device of Claim 3, the second force sensor further comprising:
a second area of overlap between the second force sensor electrode and the second conductive portion, the second are of overlap configured to vary in response to a rotational relative motion between the first substrate and the second substrate.

6. The input device of Claim 1, wherein the second substrate consists of a conductive material and the first force sensor further comprises:

a first area of overlap between the first force sensor electrode and an aperture formed in the second substrate, wherein a force applied in a direction parallel to the input surface varies the first area of overlap and changes the first variable capacitance..

7. The input device of Claim 1, wherein the first conductive portion of the second substrate of the first force sensor comprises a conductive material disposed on the second substrate.

8. The input device of Claim 1, the second force sensor further comprising:
a third first force sensor electrode disposed on the first substrate, the third force sensor electrode capacitive coupled to the second force sensor electrode and configured to move relative to the second conductive portion such that the second variable capacitance changes in response to parallel relative motion between the first substrate and the second substrate.

9. The input device of Claim 1, further comprising:
a processing system communicatively coupled to the at least one sensor electrode and the first and second force sensor electrodes, the processing system configured to:
determine positional information for input objects in the sensing region;

determine a first capacitance value based on the first variable capacitance and a second capacitance value based on the second variable capacitance; and
determine force information for the force applied to the input surface using the first and second capacitance values.

10. An input device comprising a sensing region overlapping an input surface of the input device, the input device comprising:

at least one sensor electrode disposed on a first substrate, the at least one sensor electrode configured to detect input objects in the sensing region of the input device;

a plurality of force sensor electrodes disposed on the first substrate, the first substrate physically coupled to a second substrate and configured to move relative to the second substrate;

a first variable capacitance comprising:

a capacitive coupling between at least one force sensor electrode of the plurality of force sensor electrodes disposed on the first substrate and a first conductive portion of the second substrate;

a second variable capacitance comprising:

a capacitive coupling between at least one force sensor electrode of the plurality of force sensor electrodes disposed on the first substrate and a second conductive portion of the second substrate;

wherein a force applied to the input surface in a first direction parallel to the input surface moves the first substrate relative to the second substrate and changes at least one of the first and second variable capacitances.

11. The input device of Claim 10, wherein the first variable capacitance remains substantially constant in response to the force applied to the input surface in a first direction parallel to the input surface, wherein the movement of the first substrate relative to the second substrate comprises parallel relative motion.

12. The input device of Claim 11, wherein a force applied to the input surface in a direction perpendicular to the input surface moves the first substrate relative to the second substrate and changes first variable capacitance.

13. The input device of Claim 12, wherein the second variable capacitance remains substantially constant in response to the force applied to the input surface in a direction perpendicular to the input surface causing movement of the first substrate relative to the second substrate.

14. The input device of Claim 10, wherein the first variable capacitance comprises:

a capacitive coupling between at least two force sensor electrodes of the plurality of force sensor electrodes disposed on the first substrate and the first conductive portion of the second substrate; and

wherein the second variable capacitance comprises:

a capacitive coupling between at least two force sensor electrodes of the plurality of force sensor electrodes disposed on the first substrate and the second conductive portion of the second substrate.

15. The input device of Claim 10, further comprises:

a third variable capacitance comprising:

a capacitive coupling between at least one force sensor electrode of the plurality of force sensor electrodes disposed on the first substrate and a third conductive portion of the second substrate; and

wherein rotational relative movement between the first and second substrate in response to the force applied in the first direction parallel to the input surface changes the third variable capacitance.

16. A processing system for an input device, the input device comprising an input surface overlapped by a sensing region; the processing system comprising:

a sensor module comprising force sensor circuitry, the sensor module configured to:

operate at least one sensor electrode disposed on a first surface of a first substrate of the input device to capacitively detect input objects in the sensing region;

transmit transmitter signals using a first sub-set of a plurality of force sensor electrodes disposed on a second surface of the first substrate, the

second surface opposite the first surface;

receive resulting signals using a second sub-set of the plurality of force sensor electrodes disposed on the second surface;

a determination module configured to:

determine a first force value based on a first resulting signal received on a first force sensor electrode of the second sub-set, wherein the first resulting signal varies in response to lateral motion of a first conductive portion of a second substrate physically coupled and configured to move relative to the first substrate, the first conductive portion disposed opposite the first force sensor electrode of the second sub-set;

determine a second force value based on second resulting signal received on a second force sensor electrode of the second sub-set, wherein the second resulting signal varies in response to lateral motion of a second conductive portion of the second substrate, the second conductive portion disposed opposite the second force sensor electrode of the second sub-set; and

determine a lateral force applied to the input surface based on the first and second force values.

17. The processing system of Claim 16, wherein the determination module is further configured to:

determine positional information for input objects in the sensing region using the at least one sensor electrode;

determine force information for input objects in the sensing region based on the positional information, the first force value, and the second force value; and

enable a user interface action based on the determined force information.

18. The processing system of Claim 16, wherein the determination module is further configured to:

determine a third force value based on a third resulting signal received on a third force sensor electrode of the second sub-set, wherein the third resulting signal varies in response to vertical motion of the second conductive portion of the second substrate, the second conductive portion disposed opposite the third force sensor electrode of the second sub-set; and

determine the lateral force applied to the input surface based on the first, second and third force values.

19. The processing system of Claim 18, wherein the determination module is configured to determine the lateral force applied to the input surface by:

determining a lateral force component in a first direction to the input surface based on the first and third force values; and

determining a lateral force component in a second direction to the input surface based on the second and third force values.

20. The processing system of Claim 16, wherein the determination module is further configured to:

determine a third force value based on a third resulting signal received on a third force sensor electrode of the second sub-set, wherein the third resulting signal varies in response to lateral motion of a third conductive portion of the second substrate, the third conductive portion disposed opposite the third force sensor electrode of the second sub-set; and

determine a rotational force applied to the input surface based on at least the first and third force values.

* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family
