Title: LIGHT FOR ORAL ANESTHESIA INJECTION SYRINGE

Abstract: A light for use with an oral anesthesia syringe that is received into a passageway of a barrel of the light. When the syringe is received into a first opening in a proximal end of the barrel's passageway, the needle of the syringe extends through a second opening at the proximal end of the barrel. At least one lamp and preferably a plurality of lamps at the distal end of the barrel illuminate the needle and the interior of a patient's mouth. A battery is included in the light for powering the lamps. The insertion of the syringe into the barrel may a pair of contacts to cause the battery to power the lamps, or the battery may be removed to remove power from the lamps. A disposable integrated syringe and light combination is also described.

BACKGROUND OF THE INVENTION

[0015] 1. Field of the Invention: The present invention relates, in general, to the administration of oral anesthesia into a patient's mouth using a syringe, and, in particular, to lighting of the interior of a patient's mouth during the administration of oral anesthesia.

[0020] 2. Information Disclosure Statement: It is well-known for dentists to use prior art oral anesthesia injection syringes, such as the prior art syringe shown in Fig. 1, to anesthetize a patient's mouth during dental surgery. A problem is that access to the inside
of a patient's mouth is limited by the size of the patient's mouth opening, and it is difficult
to adequately illuminate the inside of the patient's mouth so that the dentist can view the
injection site during application of the anesthesia. Typically a light mounted on a movable
arm is used to illuminate the inside of the patient's mouth, but the dentist's head and hands
can impede illumination of the inside of the patient's mouth by the light. Also, when the
dentist moves to various injection sites inside the patient's mouth, the light on the movable
arm may have to be repositioned between injections so as to provide sufficient illumination
inside the patient's mouth.

[0025] It is therefore desirable to have a light inside the patient's mouth that directly
illuminates the desired injection sites as the oral anesthesia injection syringe is moved from
one injection site to another. It is further desirable to provide a "hands free" means of
lighting the inside of the patient's mouth that moves with the oral anesthesia injection
syringe and that does not require an additional hand to manage the positioning of the
lighting of the inside of the patient's mouth.

[0030] It is further desirable to provide a single-use disposable oral anesthesia injection
syringe that illuminates the inside of a patient's mouth.

BRIEF SUMMARY OF THE INVENTION

[0100] The present invention is a light for use with an oral anesthesia syringe that is
received into a passageway of a barrel of the light. When the syringe is received into a first
opening in a proximal end of the barrel's passageway, the needle of the syringe extends
through a second opening at the proximal end of the barrel. At least one lamp and
preferably a plurality of lamps at the distal end of the barrel illuminate the needle and the
interior of a patient's mouth. A battery is provided in the light for powering the lamps. The
insertion of the syringe into the barrel closes a pair of contacts to cause the battery to power
the lamps, or the battery may be removed in order to remove power from the lamps.

[0110] It is an object of the present invention to provide illumination of the needle of an
oral anesthesia syringe and of the anesthesia injection site within a patient's mouth. It is a
further object of the invention to provide self-contained "hands free" illumination within the
patient's mouth that moves together with the anesthesia syringe, without having cords or
wires that extend out of the patient's mouth to an external power source.

[0120] Its is a further object of the present invention to provide a single-use disposable
oral anesthesia injection syringe that illuminates the inside of a patient's mouth.

DETAILED DESCRIPTION OF THE INVENTION

Fig. 1 shows a typical well-known prior art oral anesthesia syringe 20 such as would be used with the present invention. A suitable oral anesthesia injection syringe for use with the present invention is the well-known oral anesthesia injection syringe sold by Patterson Dental Supply, Inc., 1031 Mendota Heights Rd., St. Paul, Minnesota 55120, U.S.A. The syringe 20 typically has a hypodermic needle 22 that is threadedly received onto a fitting 24 at the front or distal end 26 of the tubular body 28 of the syringe 20. A glass vial 30 of a local anesthetic is received into the body 28, and elongated side openings 32 are provided in the body 28 so that the amount of anesthetic within vial 30 can be observed. Finger grips 34 are provided for the dentist's fingers, and a thumb-operated plunger 36 is pushed into the vial 30 to cause injection of the anesthetic through the hypodermic needle 22, with an outer position of plunger 36 being shown in dotted outline.

The parts of syringe 20 are typically made of stainless steel so that the syringe 20 may be sterilized in an autoclave. The tubular body 28 of the syringe 20 has a certain body outer diameter 38, typically about 10 mm.

Figs. 2-15 of the drawings show the structure of the light 40 of the first preferred embodiment of the present invention, with Figs. 9 and 10 showing an alternate embodiment, described hereinbelow, of the circuitry.

Light 40 includes a barrel 42 having a proximal end 44 and a distal end 46, and barrel 42 has a first opening 48 at proximal end 44 and a second opening 50 at distal end 46. Barrel 42 further has a longitudinal passageway 52 therethrough from first opening 48 to second opening 50, with passageway 52 having a transverse inner diameter 54 larger than
the certain body outer diameter 38, for closely receiving the tubular body 28 of syringe 20 therewithin, with the tubular body 28 of syringe 20 extending through the first opening 48 and with the needle 22 extending out of the second opening 50 as best seen in Fig. 12. Preferably the transverse inner diameter 54 is about 1 mm or so larger than the certain body outer diameter 38 so that the syringe 20 will be frictionally retained within the passageway 52 of light 40. It will be understood that first opening 48, second opening 50, and passageway 52 are preferably co-axial on the longitudinal axis of barrel 42.

[1030] Light 40 further includes an electrical circuit 56 including at least one lamp 58 and preferably a plurality of lamps 58, such as the three light emitting diode ("LED") lamps shown in the preferred embodiments of light 40, proximate the distal end 46 of barrel 42, preferably encircling second opening 50 so as to fully illuminate the needle 22 and the anesthesia injection site in the patient's mouth. Electrical circuit 56 preferably includes a printed circuit pattern on a piece of flexible mylar 60 having a ring 62 with a center hole 64 to allow the needle of the syringe 22 to pass therethrough. Each lamp 58 is respectively mounted within a pair of holes 66, 68 in ring 62 that complete the circuit to a battery 70. Battery 70 is preferably rechargeable, as by putting battery 70 in a well-known battery charger, and is received in a battery compartment 72 of barrel 42. Battery 70 has a pair of contacts 74, 76 that contactingly and matingly engage contacts 78, 80 on the mylar circuitry. Battery 70 is preferably asymmetrically shaped to match the opening 82 of compartment 72 so that battery 70 can only be inserted correctly into compartment 72, and a plurality of small transverse channels 84 are preferably provided on an outer surface of battery 70 for ease of removal of the battery 70 as by engaging channels 84 with a user's fingernail through an access opening 85 into battery compartment 72. If desired, contacts 78, 80 on the mylar circuitry may be provided with springs 86, 88 to provide better contact with contacts 74, 76 of battery 70.

[1040] In the first embodiment 56 of the electrical circuit, power is applied to lamps 58 when the battery 70 is inserted into the battery compartment 72, thereby completing the circuit as battery contacts 74, 76 connectingly engage with contacts 78, 80 on the mylar circuitry. Likewise, power is removed from lamps 58 when the battery 70 is removed from the battery compartment 72.

[1050] An alternate or second embodiment 56' of the electrical circuit is shown in Figs. 9 and 10, in which a modified version 60' of the mylar circuitry is used. It shall be understood that many aspects of the two preferred embodiments of the electrical circuits 60, 60' are substantially the same, and only the differences will be treated in detail, it being understood that similar structural features of the two embodiments perform similar
functions.

In the second embodiment 56' of the electrical circuit, the electrical circuit 56' includes a pair of contacts 90, 92, preferably leaf spring contacts as shown, interposed between battery 70 and lamps 58. Contacts 90, 92 have a first condition, when the tubular body 28 of syringe 20 is not received within passageway 52, in which there is no electrical continuity between contacts 90, 92 (see solid outline of syringe 20 in Fig. 9), and a second condition, when the tubular body 28 of syringe 20 is received within passageway 52 (see dotted outline of syringe 20' in Fig. 9, and solid outline of syringe 20 in Fig. 10), in which there is caused to be electrical continuity between contacts 90, 92. Preferably this second condition of electrical continuity is made by the metal of tubular body 28 of syringe 20 completing the circuit between contacts 90, 92 and causing current to flow between contacts 90 and 92 through the conducting metal of tubular body 28, but the electrical continuity may be caused by mechanical engagement of tubular body 28 with one or both of contacts 90, 92 so as to cause contacts 90 and 92 to directly engage each other for current flow therebetween.

Preferably, the barrel 42 may include one or more elongated viewing openings 94, 96 so that the amount of anesthetic within vial 30 of syringe 20 can be observed during administration of local anesthesia to the patient. A cap 98 is preferably included at the distal end 46 of barrel 42 with there being a slot 100 in cap 98 in alignment with each lamp 58 to allow illumination from lamps 58 to pass to the anesthesia site and to the needle 22. Light 40 is preferably constructed of materials allowing disinfecting of the light before and after use.

To use the light of the first preferred embodiment of the present invention, the battery 70 is first charged in a well-known battery charger and then is inserted into the battery compartment 72. The hypodermic needle 22 is threadedly received onto fitting 24, and a vial 30 of anesthetic is placed within the syringe 20, and the syringe 20 is then inserted into and received within the passageway 52 of the light 40, with the tubular body 28 of the syringe 20 extending through the first opening 48 and with hypodermic needle 22 extending out of second opening 50. The lamps 58 will illuminate the needle 22 and the anesthesia injection site within the patient's mouth as the syringe 20 is used.

Figs. 16-24 show a second preferred embodiment of an oral injection syringe 2.40 of the present invention, in which the syringe and the light are provided as an integrated unit. Figs. 26-33 show a third preferred embodiment of the light 3.40 of the present invention. Like the first preferred embodiment 40 of the light of the present invention, the third embodiment light 3.40 of the present invention is used with a typical
well-known prior art oral anesthesia syringe 20 as previously described in connection with
the first embodiment light 40 and as shown in Fig. 1.

[1100] The construction of the second preferred embodiment 2.40 permits the syringe
with light combination 2.40 to be provided pre-sterilized in a sealed sterile package that is
opened when the syringe is needed to be used. Such a syringe and light combination 2.40
permits the syringe and light combination to be disposed after the single use, thereby
reducing or eliminating the possibility of contamination from patient to patient of germs
that are difficult if not impossible to kill by standard autoclave or chemical sterilization
practices. While the syringe and light combination of the present invention could be
sterilized by standard autoclave or chemical sterilization procedures, the inexpensive
construction of the syringe and light combination of the present invention permits greater
patient safety at minimal cost by having the syringe and light combination 2.40 be
disposable and single use. Identifying reference designators for the second preferred
embodiment 2.40 of the invention and the third preferred embodiment 3.40 of the present
invention are marked similarly to the first embodiment, with the reference designators for
the second preferred embodiment having a prefix of "2." and with the reference designators
for the third preferred embodiment having a prefix of "3." and with similar structural
features of the first, second, and third embodiments having the same suffix (e.g., "40",
"2.40", "3.40", etc.). It shall be understood that many aspects of the three preferred
embodiments are substantially the same, and only the differences will be treated in detail, it
being understood that similar structural features of the various embodiments perform
similar functions.

[1110] Syringe with light combination 2.40 includes a body 2.28 having a proximal end
2.44 and a distal end 2.46, with distal end 2.46 being adapted, as by threaded fitting 2.24,
for receipt of a hypodermic needle 2.22. As with all embodiments, the syringe body 2.28
receives therewithin a vial 30 of local anesthetic. Just as with prior art oral anesthesia
syringes, embodiment 2.40 includes a thumb-operated plunger 2.36 that has a barb 2.37 that
is engagingly pushed into the rubber plug 31 of anesthetic vial 30.

[1120] Syringe with light combination 2.40 also preferably includes a collet or
cylindrically-symmetric sleeve 2.102 and compression spring 2.104 mounted upon the shaft
2.35 of plunger 2.36, as best seen in Fig. 25. Compression spring 2.104 preferably tapers
from an outer diameter of about 8.8 mm at its proximal end 2.106 to an outer diameter of
about 9.75 mm at its distal end 2.108, and distal end 2.108 engages with and is held by a
nipple 2.110 of sleeve 2.102. Preferably one "dead" coil at the proximal end 2.106 of
spring 2.104 and two "dead" coils at the distal end 2.108 of spring 2.104, and spring 2.104
preferably has a compression force of about 70 g/mm. The purpose of spring 2.104 and
sleeve 2.102 is to retain vial 30 within the syringe body 2.28 as best seen in Fig. 25. An
encircling wire clip 2.112, received in circumferential groove 2.114 of shaft 2.35, retains
spring 2.104 and sleeve 2.102 on shaft 2.35 when anesthesia vial 30 is not present. After
the anesthesia has been administered, plunger 2.36 can be retracted, such that wire clip
2.112 will engage with the narrowed bore 2.116 of sleeve 2.102, thereby retracting sleeve
2.102 against compression spring 2.104 as barb 2.37 disengages from plug 31, thereby
allowing the used anesthesia vial 30 to be removed.

[1130] Syringe with light combination 2.40 includes an electrical circuit 2.56 integral
with syringe and light combination 2.40, including at least one lamp 2.58 and preferably
three lamps 2.58. Electrical circuit 2.56 preferably includes a first circuit board 2.57 and a
second circuit board 2.59, interconnected by wires 2.61. Mounted to first circuit board 2.57
are one or more batteries 2.70, each within a well-known battery holder 2.74. Preferably at
least one of batteries 2.70 completes its circuit through a contacting plated-through hole
2.78 on circuit board 2.57, and an insulating strip 2.118 is interposed between plated-
through hole 2.78 and battery 2.70, thereby interrupting the contact to battery 2.70. When
circuit board 2.57 is mounted into battery compartment 2.72, plated-through hole 2.78 is
exposed and insulating strip 2.118 is left hanging outside the battery compartment 2.72, as
best seen in Fig. 18. To test the operation of electrical circuit 2.56, a conducting (metallic)
needle is inserted through plated-through hole 2.78 and through insulating strip 2.118 to
battery 2.70, thereby completing the circuit between battery 2.70 and plated-through hole
2.78, thereby causing lamps 2.58 to illuminate for testing during manufacture. Removal of
the test needle again causes battery 2.70 to be insulated from plated-through hole 2.78 by
insulating strip 2.118, and the top 2.73 of battery compartment 2.72 is closed with
insulating strip 2.118 extending outside of battery compartment 2.72, again as best seen in
Fig. 18.

[1140] To illuminate the lamps 2.58 during normal use by a dentist, the dentist simply
pulls the insulating strip 2.118 from the battery compartment 2.72 (see dotted lines in Figs.
19 and 20), thereby permitting plated-through hole 2.78 to contact battery 2.70, thereby
completing the circuit and causing the battery to power lamps 2.58. Insulating strip 2.118 is
thus seen to function as a single-use switch to turn the lamps on during use.

[1150] Second circuit board 2.59 is mounted to distal end 2.46 of body 2.28, and a
transparent cap 2.98 covers circuit board 2.59 and lamps 2.58, and lamps 2.58 shine through
transparent cap 2.98.

[1160] With the exception of spring 2.104, electrical circuit 2.56, and wire clip 2.112,
all parts of second embodiment 2.40 are preferably constructed of a sterilizable plastic so that second embodiment 2.40 can be sterilized, enclosed in a sterile package, opened by the dentist and used, and then discarded after use on a single patient, thereby reducing transmission of germs and diseases between patients. The dentist uses the second embodiment to administer anesthetic just as with the first embodiment.

Improvements have been made to the third preferred embodiment light 3.40, hereinafter described, that provide for ease of construction and assembly as compared to the first preferred embodiment, and the third preferred embodiment light 3.40 is disposable so that it can be pre-sterilized and provided in a sealed sterile package that is opened when the syringe is needed to be used, and then the third preferred embodiment light 3.40 can be disposed of after its single use. Additionally, because the third preferred embodiment is used with a well-known oral injection syringe that has already been approved by governmental approval bodies for use in dentistry with patients, regulatory approval is not required for the third preferred embodiment light 3.40 that attaches to the already-approved oral injection syringe. Otherwise, the third embodiment has many similarities to the first and second embodiments.

Light 3.40 includes a barrel 3.42 having a proximal end 3.44 and a distal end 3.46, and barrel 3.42 has a first opening 3.48 at proximal end 3.44 and a second opening 3.50 at distal end 3.46. Barrel 3.42 further has a longitudinal passageway 3.52 therethrough from first opening 3.48 to second opening 3.50, with passageway 3.52 having a transverse inner diameter 3.54 larger than the certain body outer diameter 38, for closely receiving the tubular body 28 of syringe 20 therewithin, with the tubular body 28 of syringe 20 extending through the first opening 3.48 and with the needle 22 extending out of the second opening 3.50 as best seen in Figs. 26 and 28. Preferably the transverse inner diameter 3.54 is about 1 mm or so larger than the certain body outer diameter 38 so that the syringe 20 will be frictionally retained within the passageway 3.52 of light 3.40. It will be understood that first opening 3.48, second opening 3.50, and passageway 3.52 are preferably co-axial on the longitudinal axis of barrel 3.42.

Light 3.40 further includes an electrical circuit 3.56 including at least one lamp 3.58 and preferably a plurality of lamps 3.58, such as the two light emitting diode ("LED") lamps shown in the preferred embodiments of light 3.40, proximate the distal end 3.46 of barrel 3.42, preferably around second opening 3.50 so as to fully illuminate the needle 22 and the anesthesia injection site in the patient's mouth.

Referring especially to Fig. 33, third embodiment 3.40 of the light includes a battery compartment 3.72 that holds a battery holder 3.73 having metallic left and right
battery contacts 3.74 and 3.76. It should be noted that right battery contact 3.76 has a small
together and a similar small access hole 3.79 through the right
wall of battery compartment 3.72. The left battery contact 3.74 has an inwardly-bent
triangular flap 3.80 that engages the positive ("+") terminal of the leftmost battery 3.70
when all three batteries 3.70 are inserted into the battery holder 3.73. Similar to the second
embodiment, an insulating strip 3.118 is interposed between right battery contact 3.76 and
rightmost battery 3.70, thereby interrupting the circuit and preventing batteries 3.70 from
supplying power to the lamps 3.58. After light 3.40 has been assembled, proper operation
of circuit 3.56 can be tested by inserting a conducting metallic needle through hole 3.78
from the outside of battery compartment 3.72, through insulating strip 3.118, and contacting
the rightmost battery 3.70, thereby completing the circuit between rightmost battery 3.70
and contact 3.76 and allowing batteries 3.70 to supply power to the lamps 3.58.

[1210] As seen in Fig. 33, wires 3.61 carry the current to and from lamps 3.58 via
circuit board 3.59, and wires 3.61 are received into longitudinal grooves 3.63 within barrel
3.42. A snap-in circuit cover 3.71, having a plurality of laterally-extending tabs 3.120 that
matingly engage channels 3.122 in barrel 3.42, is provided to produce a sealed unit, with
insulating strip 3.118 extending out of the battery compartment. A transparent cap 3.98 is
then fitted to distal end 3.46 of barrel 3.42 over circuit board 3.59 and LED lamps 3.58.

[1220] To illuminate the lamps 3.58 during normal use by a dentist, the dentist simply
pulls the insulating strip 3.118 from the battery compartment 3.72 (see dotted line in Fig.
32), thereby permitting battery contact 3.76 to contact rightmost battery 3.70, thereby
completing the circuit and causing the battery to power lamps 3.58. Insulating strip 3.118 is
thus seen to function as a single-use switch to turn the lamps on during use.

[1230] With the exception of electrical circuit 3.56, all parts of third embodiment 3.40
are preferably constructed of a sterilizable plastic so that third embodiment 3.40 can be
sterilized, enclosed in a sterile package, opened by the dentist and used, and then discarded
after use on a single patient, thereby reducing transmission of germs and diseases between
patients. The dentist uses the third embodiment to administer anesthetic just as with the
first and second embodiments.

INDUSTRIAL APPLICABILITY

[4500] The light of the present invention has industrial applicability when used with an
oral anesthesia injection syringe in that it illuminates the needle and the interior of a
patient's mouth during injection of an oral anesthetic. The light is self-contained and
unobtrusive and permits "hands free" operation, following the needle as the syringe is
moved within the patient's mouth. Disposable single-use embodiments are provided that
are pre-sterilized and discarded after use, thereby reducing transmission of germs from one
patient to another.

Although the present invention has been described and illustrated with respect to
a preferred embodiment and a preferred use therefor, it is not to be so limited since
modifications and changes can be made therein which are within the full intended scope of
the invention.
We claim:

1. A light for use with an oral anesthesia injection syringe having a tubular body with a certain body outer diameter, said light comprising:
   (a) a barrel having a proximal end and a distal end, said barrel having a first opening at said proximal end and a second opening at said distal end and a longitudinal passageway through said barrel from said first opening to said second opening, said passageway having a transverse inner diameter larger than said certain body outer diameter for receiving the tubular body of the syringe within said passageway with the tubular body of the syringe extending through said first opening and with the needle extending out of said second opening; and
   (b) an electrical circuit including:
      i. at least one lamp proximate said distal end of said barrel; and
      ii. a battery received into a compartment of said barrel for powering said at least one lamp.

2. The light as recited in claim 1, in which said electrical circuit further includes a pair of contacts interposed between said battery and said at least one lamp, said pair of contacts having a first condition in which there is no electrical continuity between said contacts when the tubular body of the syringe is not received within said passageway, and having a second condition in which there is caused to be electrical continuity between said contacts when the tubular body of the syringe is received within said passageway.

3. The light as recited in claim 1, in which said light is pre-sterilized and disposable after use on a single patient.
4: In combination, an oral anesthesia injection syringe having a tubular body with a
certain body outer diameter, and a light, said light comprising:

(a) a barrel having a proximal end and a distal end, said barrel having a first
opening at said proximal end and a second opening at said distal end and a
longitudinal passageway through said barrel from said first opening to said
second opening, said passageway having a transverse inner diameter larger
than said certain body outer diameter; and

(b) an electrical circuit including:

i. at least one lamp proximate said distal end of said barrel; and

ii. a battery received into a compartment of said barrel for powering said at
least one lamp;

said tubular body of said syringe being received within said passageway with said
tubular body of said syringe extending through said first opening and with said needle
extending out of said second opening.

5: The light as recited in claim 4, in which said electrical circuit further includes a
pair of contacts interposed between said battery and said at least one lamp, said pair of
contacts being caused to have electrical continuity therebetween by said tubular body of the
syringe being received within said passageway.

6: The light as recited in claim 4, in which said light is pre-sterilized and disposable
after use on a single patient.
7: An oral anesthesia injection syringe having a body, said body having a proximal end and a distal end, said distal end of said syringe being adapted for receipt of a hypodermic needle thereon, said syringe including an electrical circuit integral therewith, said electrical circuit including:

(a) at least one lamp proximate said distal end of said body; and
(b) a battery received into a compartment of said body for powering said at least one lamp.

8: The syringe as recited in claim 7, in which said syringe is pre-sterilized and disposable after use on a single patient.
### INTERNATIONAL SEARCH REPORT

**International application No.**

PCT/US 14/13251

---

**A. CLASSIFICATION OF SUBJECT MATTER**

IPC(8) - A61M 5/178 (2014.01)

USPC - 433/28, 29, 87, 90: 607/88

According to International Patent Classification (IPC) or to both national classification and IPC

---

**B. FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)

IPC(8) - A61M 5/178

USPC - 433/28. 29. 87. 90; 607/88

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched 433/80, 89; 604/77, 187, 218; 607/88-95; 606/2, 10, 13; 362/372. 573; A61M 5/28

* Special categories of cited documents:

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier application or patent but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referred to in an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

**"T"** later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

**"X"** document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

**"Y"** document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

**"&"** document member of the same patent family
