A one-piece barrel assembly cart includes a right assembly cart base connected with a left assembly cart base and at least three stabilizer rings that are attached to the assembly cart base. The one-piece barrel assembly cart may be used to stabilize a tapered cured composite barrel, for example the large fuselage barrel of the aft section of a large new generation aircraft, such as a 7E7 Boeing airplane. A modular assembly cart includes at least two identical modules. Each of these modules includes a cart base and a stabilizer ring. The diameter of the inner surface of the stabilizer ring may vary as needed. Other modules including a fuselage support may be added. By providing modular assembly carts any shape and size of a one-piece composite barrel may be stabilized after curing of the composite material.

CROSS REFERENCE TO RELATED APPLICATIONS

BACKGROUND OF THE INVENTION

The present invention generally relates to assembly fixtures and, more particularly, to an assembly cart for a large one-piece composite fuselage barrel and to a method for stabilizing large cured composite fuselage barrels.

In recent years, Boeing Commercial Airplanes has focused its new airplane product development efforts on the Boeing 7E7, a super-efficient airplane. In addition to bringing big-jet ranges to mid-size airplanes, the 7E7 will provide airlines with unmatched fuel efficiency, resulting in exceptional environmental performance. The airplane may use 20 percent less fuel for comparable missions than any other wide-body airplane. Furthermore, the airplane will be able to travel at speeds similar to today's fastest wide bodies, about Mach 0.85. Still further, the wide body aircraft 7E7 may provide 40 to 60 percent more cargo revenue capacity. The key to this exceptional performance is a suite of new technologies being developed by Boeing and its international technology development team. For example, the majority of the primary structure, including the fuselage and wing, on the 7E7 will be made of composite materials. Construction materials may be used (by weight) as follows: about 57% composite materials, about 24% aluminum, about 11% titanium, and about 8% steel. By volume, the 7E7 will be about 80% composite materials. Composite material are significantly lighter than traditional aircraft materials, such as aluminum and aluminum alloys, titanium and titanium alloys, and steel. The use of composite materials will make
the 7E7 a very light aircraft for its capabilities.

[004] Since composite materials have material characteristics that differ from traditional aircraft materials it will not be possible to use existing facilities and equipment for the construction and assembly of the 7E7. For example, the large fuselage sections that will be made out of a composite material and which will have a one-piece barrel shape will be built on an inner mold line mandrel. After curing of the composite material, such as a graphite/epoxy, the inner mold line mandrel needs to be removed. The fuselage sections will be approximately 24 feet long and will have a diameter of about 19.5 feet and, therefore, are quite large. Furthermore, composite material in post-cure condition is not as stiff as traditional material, such as aluminum or titanium and their alloys, used to build fuselage sections. Furthermore, composite material in post-cure condition will not be stiff enough to be moved around. Therefore, a large fuselage barrel having a diameter of about 19 feet and a length of at least 24 feet would collapse under its own weight if the inner mold line mandrel were to be removed without stabilizing or holding the fuselage barrel. Currently, no equipment exists that could hold or carry such large structure as the fuselage barrel of the 7E7. Furthermore, the 7E7 will consist of at least 3 fuselage sections that need to be joined with each other. In order to join two adjacent fuselage barrels, the barrels will need to be moved toward each other and the barrels also will need to be aligned. Currently no equipment exists that would allow the transport and alignment of the large fuselage barrels. Since the different fuselage sections of a large new generation aircraft, such as the 7E7, for example, the aft section, the center section, and the forward section, will not have the same size, shape and fuselage features, equipment for carrying and holding these fuselage sections is needed that may be easily adjusted to the features of each fuselage section.

[005] As can be seen, there is a need for developing new equipment that is able to stabilize, hold, and carry large fuselage barrels without frames having a diameter of about 19 feet and a length of more than 24 feet, such as the fuselage barrels of the 7E7 airplane. Furthermore, there is a need to prevent large one-piece composite fuselage barrels, such as the fuselage barrels of the 7E7, from collapsing under their own weight during removal of the inner mold line mandrel. Also, there is a need to provide new equipment for holding and carrying large fuselage barrels, such as the fuselage barrels of the 7E7, that may be easily adjusted to the size and shape of the fuselage barrel.
Moreover, there is a need to provide equipment that allows the joining of adjacent fuselage barrels having a diameter of about 19 feet and a length of more than 24 feet.

[006] There has, therefore, arisen a need to provide an assembly structure for large one-piece composite fuselage barrels having a diameter of about 19 feet and a length of more than 24 feet. There has further arisen a need to provide an assembly structure that has modular components, which are easily adjustable to the shape and size of a large one-piece composite fuselage barrel. There has still further arisen a need to provide a method for stabilizing large cured composite fuselage barrels.

SUMMARY OF THE INVENTION

[007] The present invention provides an assembly cart for a one-piece composite fuselage barrel having a diameter of about 19 feet and a length of more than 24 feet, and a method for stabilizing large one-piece composite fuselage barrels. The present invention further provides a fixture consisting of multiple ring assemblies that may be suitable for, but not limited to, securing a large one-piece fuselage barrel shell made out of a composite material of a large new generation aircraft, such as the Boeing 7E7 airplane. The present invention still further provides a modular assembly system that includes assembly fixtures that may be easily adjusted to the size and shape of the one-piece composite fuselage barrel.

[008] In one aspect of the present invention, a one-piece barrel assembly cart comprises a right assembly cart base having an inner surface, a left assembly cart base having an inner surface, at least two stabilizer rings, and a plurality of clamps. The left assembly cart base is connected with the right assembly cart base at the inner surfaces. Each stabilizer ring is divided into a right half and a left half. The right half is attached to the right assembly cart base and the left half is attached to the left cart base. The clamps are attached to the stabilizer rings.

[009] In another aspect of the present invention, a post-cure assembly cart comprises a track, a right sliding base positioned on the track, a left sliding base positioned on the track opposite from the right sliding base, a stabilizer ring having an inner surface and an outer surface and including a right half and a left half, end s plurality of clamps attached to the inner surface of the stabilizer ring. The right half of the stabilizer ring is attached to the right sliding base and the left half of the stabilizer
ring is attached to the left sliding base.

[010] In still another aspect of the present invention, a modular assembly cart comprises a first module including a first cart base and a first stabilizer ring, a second module including a second cart base and a second stabilizer ring, and a third module including a third cart base and a third stabilizer ring. The second cart base is connected with the first cart base. The third cart base is connected with the second cart base.

[011] In a further aspect of the present invention, a modular assembly cart comprises a first module and a second module. The first module includes a cart base having a front, a back, a top and a bottom, two rails located at the top of the cart base and extending longitudinally from the front to the back at opposite sides, a stabilizer ring having a lower half and an upper half, and a fuselage support installed on top of the cart base. The lower half is mounted on the rails proximate to the front of the cart base and the upper half is detachable from the lower half of the stabilizer ring. The second module is connected with the first module. The second module is identical with the first module. The back of second module is attached to the back of the first module.

[012] In still a further aspect of the present invention, a post-cure assembly cart for a fuselage barrel of the aft section of an airplane comprises a right assembly cart base, a plurality of casters attached to the bottom and evenly distributed along the outer surface and the inner surface of the right assembly cart base and of the left assembly cart base, a plurality of support jack assemblies attached to the bottom and evenly distributed along the outer surface and the inner surface of the right assembly cart base and of the left assembly cart base, a plurality of pitch and yaw jack assemblies attached to the bottom and evenly distributed along the outer surface and the inner surface of the right assembly cart base and of the left assembly cart base, three ring guides being in a fixed connection with the outer surface of the right assembly cart base, three ring guides being in a fixed connection with the outer surface of the left assembly cart base, three stabilizer rings, a plurality of clamps being attached to the inner surface of the stabilizer rings, and a plurality of ring support jack assemblies mounted underneath each of the stabilizer rings. The right assembly cart base includes an inner surface, an outer surface, and a bottom. The left assembly cart base includes an inner surface, an outer surface, and a bottom. The left assembly cart base has the same dimensions as the left assembly cart base. The left assembly cart base is connected with the right assembly cart base at the inner surfaces. Each stabilizer ring has an inner surface and an outer
surface. Each stabilizer ring is divided into a right half and a left half. The right half of each stabilizer ring is attached to one of the ring guides of the right assembly cart base. The left half of each stabilizer ring is attached to one of the ring guides of the left cart base. The right half and the left half of the stabilizer ring are detachable. The outer surface of each of the three stabilizer rings has the same diameter. The inner surface of a first stabilizer ring has a first diameter. The inner surface of a second stabilizer ring has a second diameter. The inner surface of a third stabilizer ring has a third diameter.

[013] In still another aspect of the present invention, a method for stabilizing a cured composite fuselage barrel comprises the following steps: providing an assembly cart supporting at least two stabilizer rings including a plurality of clamps, a first half, and a second half; opening the stabilizer rings by detaching the first half of each of the stabilizer rings from the second half; inserting a fuselage barrel into the stabilizer rings; closing the stabilizer rings by connecting the first half of each of the stabilizer rings with the second half; and actuating clamps and attaching the fuselage barrel to the stabilizer rings.

[014] These and other features, aspects and advantages of the present invention will become better understood with reference to the following drawings, description and claims.

DETAILED DESCRIPTION OF THE INVENTION

The following detailed description is of the best currently contemplated modes of carrying out the invention. The description is not to be taken in a limiting sense, but is made merely for the purpose of illustrating the general principles of the invention, since the scope of the invention is best defined by the appended claims.

The Boeing Company is exploring a variety of methods and tools for making large composite structures. The present application describes an invention that is one of a family of inventions for accomplishing this goal. The present application is related to the following co-pending United States patent applications that are part of this family: U.S. application no. 10/851,381, filed May 20, 2004, entitled "Composite Barrel Sections for Aircraft Fuselages and Other Structures, and Methods and Systems for Manufacturing such Barrel Sections"; U.S. application no. 10/822,538, filed April 12, 2004, entitled "Systems and Methods for Using Light to Indicate Defect Locations on a Composite Structure"; U.S. application no. 10/717,030, filed November 18, 2003, entitled "Method of Transferring Large Uncured Composite Laminates"; U.S. patent application no. 10/646,509, entitled "Multiple Head Automated Composite Laminating Machine For The Fabrication Of Large Barrel Section Components", filed August 22, 2003; U.S. patent application no. 10/646,392, entitled "Automated Composite Lay-Up To An Internal Fuselage Mandrel", filed August 22, 2003; U.S. patent application no. 10/646,316, entitled "Unidirectional, Multi-Head Fiber Placement", filed August 22, 2003; U.S. patent application no. 10/630,594, entitled "Composite Fuselage Machine", filed July 28, 2003; and U.S. patent application no. 10/301,949, entitled "Parallel Configuration Composite Material Fabricator", filed November 22, 2002; all of which are assigned to the assignee of the present invention and all of which are hereby incorporated by reference into the present application.
Broadly, an embodiment of the present invention provides an assembly cart for a one-piece composite fuselage barrel that may stabilize a large cured composite fuselage barrel, for example, having a diameter of about 19 feet and a length of more than 24 feet. Since prior art fuselage barrels of traditional aircraft are typically not made out of composite materials or have a smaller size, no assembly fixture exists that may be used to assemble such a large cured composite fuselage structure. The post-cure assembly cart as in one embodiment of the present invention may be used for, but is not limited to, the assembly of large one-piece fuselage barrels of new generation aircraft such as the Boeing 7E7 airplane. Furthermore, by providing a cart base that includes casters and jack assemblies, the assembly cart as in one embodiment of the present invention may be used to mate adjacent large composite fuselage barrels. By providing modular assembly carts as in one embodiment of the present invention, the assembly cart may be used for other applications in the aerospace industry or other industries where it may be necessary to provide stabilization to large cured composite structures.

In one embodiment, the present invention provides a post-cure assembly cart including rings that may be able to provide support for a tapered one-piece fuselage barrel. The rings may be dimensioned to fit around the fuselage barrel. Still further, the size of the rings and the number of the rings used to support a fuselage barrel may be selected according to the shape and the size of the fuselage barrel. Therefore, the assembly cart as in one embodiment of the invention may be used to assemble aft, center, and forward sections of a large fuselage. Furthermore, the assembly cart may split left/right for easy loading of the large fuselage barrel. Currently no structure exists that would fit around a large one-piece fuselage barrel having a diameter of about 19 feet and a length of more than 24 feet, for example, a fuselage barrel of a Boeing 7E7 airplane.

An embodiment of the present invention further provides a plurality of force limiting vacuum toggle clamps that may be positioned on the inside of each ring and around the diameter of each ring. The purpose of the clamps may be to support and stabilize the large fuselage barrel. Cured composite material, such as graphite/epoxy, that the fuselage barrel, for example, the fuselage barrel of a Boeing 7E7 airplane may be made of, may not be as stiff as typical prior art fuselage barrel materials. Furthermore, fuselage barrels having a diameter of about 19 feet and a length of more
than 24 feet may be larger than any prior art composite fuselage barrel. Therefore, the clamps are needed to prevent the large composite fuselage barrel from collapsing under its own weight. After clamping, the large composite fuselage barrel having a diameter of about 19 feet and a length of more than 24 feet will be stabilized and it may now be possible to disassemble large and heavy mandrel sections, to conduct non-destructive testing of the barrel shell, to install fuselage barrel frames and a floor, and to machine the shell as needed. Once the cured fuselage barrel is clamped to the rings, it may be rotated allowing access to different areas of the fuselage barrel, for example for assembling, machining, or inspection. In prior art, no fixture exists that would be able to provide support and rotation capability to a large cured composite structure, such as a one-piece fuselage barrel of a Boeing 7E7 airplane.

[029] An embodiment of the present invention further provides a cart base including casters and jack assemblies. The casters and jack assemblies may be used to lift the assembly cart as in one embodiment of the present invention above the ground for easy access, to move the assembly cart on the factory floor, and to mate a fuselage barrel with an adjacent fuselage barrel. Currently no fixture exists that would allow movement and alignment of large one-piece composite fuselage barrels, such as the Boeing 7E7 fuselage barrels.

[030] An embodiment of the present invention further provides a modular assembly cart. By providing a variety of modules, an assembly cart may be put together according to the shape and size of the cured composite structure that needs to be stabilized. The cured composite structure may be a large one-piece fuselage barrel of an aft, center, or front section having a diameter of about 19 feet and a length of more than 24 feet, for example, of a Boeing 7E7 airplane. Since the modules may be put together as needed, the assembly cart as in one embodiment of the present invention may be used universally.

[031] Referring now to Figure 1, a perspective side view of a post-cure assembly cart 10 is illustrated according to one embodiment of the present invention. The assembly cart 10 may include a left assembly cart base 220, a right cart base 210, a ring guide 11, a ring guide 12, a ring guide 13, a ring guide 14, a ring guide 15, a ring guide 16, a stabilizer ring 17, a stabilizer ring 18, a stabilizer ring 19, and a plurality of clamps 21. A fuselage barrel 31 may be stabilized with the assembly cart 10. The fuselage barrel 31 may be a one-piece barrel. The left assembly cart base 220 may
have an inner surface 22 and an outer surface 23. The ring guide 11, the ring guide 12, and the ring guide 13 may be in a fixed connection with the outer surface 23 of the left cart base 220. The ring guide 11 may be located at one end of the left cart base 220, the ring guide 12 may be located in the center of the left cart base 220, and the ring guide 13 may be located at the opposite end of the left cart base 220. The right assembly cart base 210 may have an inner surface 24 and an outer surface 25. The ring guide 14, the ring guide 15, and the ring guide 16 may be in a fixed connection with the outer surface 25 of the right cart base 210. The ring guide 14 may be located at one end of the right cart base 210, the ring guide 15 may be located in the center of the right cart base 210, and the ring guide 16 may be located at the opposite end of the right cart base 210.

[032] The stabilizer ring 17 may be divided into a left half 171 and a right half 172. The stabilizer ring 18 may be divided into a left half 181 and a right half 182. The stabilizer ring 19 may be divided into a left half 191 and a right half 192. The left half 171 of the stabilizer ring 17 may be attached to the ring guide 11 and the right half 172 of the stabilizer ring 17 may be attached to the ring guide 14. The left half 181 of the stabilizer ring 18 may be attached to the ring guide 12 and the right half 182 of the stabilizer ring 18 may be attached to the ring guide 15. The left half 191 of the stabilizer ring 19 may be attached to the ring guide 13 and the right half 192 of the stabilizer ring 19 may be attached to the ring guide 16. The stabilizer ring 17 may have an inner surface 173 and an outer surface 174. The stabilizer ring 18 may have an inner surface 183 and an outer surface 184. The stabilizer ring 19 may have an inner surface 193 and an outer surface 194. The diameter of the outer surfaces 174, 184, and 194 of the stabilizer rings 17, 18, and 19, respectively, may be the same. The diameter of the inner surface 173 may differ from the diameter of the inner surface 183 and the diameter of both inner surfaces 173 and 183 may further differ from the diameter of the inner surface 193. The diameters of the inner surfaces 173, 183, and 193 may be selected according to the size of the fuselage barrel 31 such that the inner surfaces 173, 183, and 193 may fit around the fuselage barrel 31. The fuselage barrel 31 may have a diameter of at least 19 feet. For example, as shown in Figure 1, the aft section of a fuselage - such as that of the Boeing 7E7 fuselage - may be tapered. Therefore, the diameter of the inner surface 173 of the stabilizer ring 17 may be smaller than the diameter of the inner surface 183 of the stabilizer ring 18, and the diameter of the inner
surface 183 of the stabilizer ring 18 may be smaller than the diameter of the inner surface 193 of the stabilizer ring 19. Furthermore, the inner surfaces 173, 183, and 193 of the stabilizer rings 17, 18, and 19, respectively, may not be a circle but a contour defined by the fuselage shape. The stabilizer rings 17, 18, and 19 may have a width (in longitudinal direction) of no more than eight inches. A plurality of clamps 21 may be attached to the inner surface 173 of ring 17, to the inner surface 183 of ring 18, and to the inner surface 193 of ring 19. The total number of locations for clamps 21 for each stabilizer ring 17, 18, and 19 to hold the fuselage barrel 31 should be preferably no less than 41 or coincide with the number of stringers in the fuselage 31.

The left cart base 220 may have the same width 26 and the same length 27 as the right cart base 210. The width 26 of the right cart base 210 and of the left cart base 220 may be selected such that once the inner surface 22 of the left cart base is connected with the inner surface 24 of the right cart base 210 (as shown in Figure 1) the left halves 171, 181, and 191 of the stabilizer rings 17, 18, and 19, respectively, are joined with the right halves 172, 182, and 192 of the stabilizer rings 17, 18, and 19, respectively. The left half 171 and the right half 172 may be joined together to form the stabilizer ring 17 using a clamping device that may be closed and opened as needed. The same applies to the stabilizer rings 18 and 19. The length 27 of the left cart base 220 and of the right cart base 210 may be selected according to the length of the fuselage barrel 31 to be stabilized. The fuselage barrel 31 may have a length of at least 24 feet. The left cart base 220 may have the same height 28 as the right cart base 210. The height 28 may be selected according to the height above the factory floor required for the assembly of the fuselage barrel 31.

The fuselage barrel 31, as shown in Figure 1, may be a tapered barrel of the aft section of a large aircraft, such as a Boeing 7E7 airplane. The barrel 31 may be made out of a composite material, for example, graphite/epoxy that has been cured. The fuselage barrel 31 may measure about 24 feet in length (expansion in longitudinal direction) and may have a diameter of about 19.5 feet. The full sized fuselage barrel 31 may be built in one piece on an inner mold line mandrel. Multiple plies of graphite tape BMS8-276, grade 190 may be used for the layup. Furthermore, the fuselage barrel 31 may include stringers (not shown) that work as longitudinal stiffeners. The clamps 21 may be positioned on the stabilizer rings 17, 18, and 19 such that each clamp 21 may be attached to the outside of the fuselage barrel 31 at the position of a longitudinal
stiffener. In order to install the fuselage barrel 31 on the post-cure assembly cart 10, the left cart base 220 may be positioned apart from the right cart base 210 leaving enough space to bring in the fuselage barrel 31. The fuselage barrel 31 may be positioned within the right halves 172, 182, and 192, of the stabilizer rings 17, 18, and 19, respectively. Then the left cart base 220 may be moved towards the right cart base 210 until the inner surface 22 of the left cart base 220 meets the inner surface 24 of the right cart base 24. The stabilizer rings 17, 18, and 19 may be closed. The stabilizer ring 18 may be positioned in the center of the fuselage barrel 31. The stabilizer rings 17 and 19 may be positioned on opposite sides of the stabilizer ring 18 having the same distance to the stabilizer ring 18. Preferably, the stabilizer rings 17 and 18 may be positioned close to each end of the fuselage barrel 31. Now the clamps 21 may be actuated to attach to the outside of the fuselage barrel 31. The clamps 21 may be, for example, automatically actuated, force limiting vacuum toggle clamps that may be able to hold the fuselage barrel. Such clamps 21 may have the ability to clamp at a new position without manual adjustment or excessive force on the fuselage barrel 31. After clamping the fuselage barrel 31 to the stabilizer rings 17, 18, and 19, the fuselage barrel 31 may be rotated. By clamping the fuselage barrel 31 to the stabilizer rings 17, 18, and 19, the cured composite fuselage barrel 31 may be stabilized in order to perform tasks, such as disassembly and removal of the layup mandrel segments, non-destructive inspection of the cured fuselage barrel 31, installation of interior fuselage structures, or joining one assembled fuselage section to another.

[035] Referring now to Figure 2, a detail 20 of an assembly cart base 220 is illustrated according to one embodiment of the present invention. The assembly cart base 220 may include casters 29, ring support jack assemblies 32, support jack assemblies 33, and pitch and yaw jack assemblies 34. The casters 29 may be attached to the bottom 281 of the cart base 220. The casters 29 may be distributed evenly in longitudinal direction next to the outer surface 23 and next to the inner surface 22. The casters 29 may swivel and may be used to move the cart base 220 along the factory floor. This may enable the insertion of the fuselage barrel 31 in the stabilizer rings 17, 18, and 19, as shown in Figure 1. The ring support jack assembly 32 may be attached to the cart base 220 underneath the stabilizer rings 17, 18, and 19. The ring support jack assembly 32 may enable alignment and rotation of the stabilizer rings 17, 18, and 19 (shown in Figure 1). The support jack assemblies 33 may be attached to the bottom
281 of the cart base 220. The support jack assemblies 33 may be positioned next to the outer surface 23 and next to the inner surface 22. The support jack assemblies 33 may provide up and down movement of the cart base 220 and, therefore, of the assembly cart 10 shown in Figure 1. The support jack assemblies 33 may be hydraulic actuators. The pitch and yaw jack assemblies 34 may be attached to the bottom 281 of the cart base 220 and may be positioned next to the outer surface 23 and next to the inner surface 22. The pitch and yaw jack assemblies 34 may be used to align the fuselage barrel 31 (shown in Figure 1) for mating with an adjacent fuselage barrel.

Referring now to Figure 3, a perspective front view of a sliding base post-cure assembly cart 30 is illustrated according to one embodiment of the present invention. The sliding base assembly cart 30 may include a track 35, a left sliding base 36, a right sliding base 37, a left half 381 of a stabilizing ring 38, and a right half 382 of a stabilizing ring 38. The left sliding base 36 and the right sliding base 37 may be positioned on opposite ends of the track 35. The left half 381 of the stabilizer ring 38 may be attached to the left sliding base 36. The right half 382 of the stabilizer ring 38 may be attached to the right sliding base 37. Before assembling the stabilizer ring 38, a fuselage barrel 39 may be positioned between the right half 382 and the left half 381 of the stabilizer ring 38. After sliding the left sliding base 36 and the right sliding base towards the center of the track 35, the right half 382 and the left half 381 form the stabilizer ring 38. The stabilizer ring 38 may be dimensioned to surround the fuselage barrel 39. The stabilizer ring 38 may have an inner surface 383 and an outer surface 384. Clamps 21, as shown in Figure 1, may be attached to the inner surface 383 and may be used to clamp the fuselage barrel 39 to the stabilizer ring 38. A plurality of left sliding bases 36 and a plurality of right sliding bases 37 may be positioned on a plurality of tracks 35. The total number of left sliding bases 36 equals the total number of right sliding bases 37 and the total number of tracks 35. Each right sliding base 37 has a right half 382 of a stabilizer ring 38 attached, and each left sliding base 36 has a left half 381 of a stabilizer ring 38 attached. The tracks 35 may be connected to expand in longitudinal direction, as shown in Figure 3. The diameter of the outer surface of all stabilizer rings 38 may be equal. The diameter of the inner surface 383 of each stabilizer ring 38 may be different and may depend on the size and shape of the fuselage barrel 39. For example, Figure 3 illustrates a large fuselage barrel 39 of a front section of a new generation aircraft, such as the Boeing 7E7 airplane. As can be seen, the inner diameter of the inner
surface 383 of the stabilizer ring 38 increases from the front to the back in longitudinal direction while the diameter of the outer surface 384 of the stabilizer ring stays the same. Consequently, the sliding base assembly cart may be assembled as needed to stabilize any shape of a large one-piece cylindrical cured composite structure, for example, the front fuselage barrel 39 of a large new generation aircraft, such as the Boeing 7E7 airplane.

[037] Referring now to Figure 4, a perspective top view of a three-ring modular assembly cart 40 is illustrated according to one embodiment of the present invention. The three-ring modular assembly cart 40 may include three identical modules 41. Each of the three modules 41 may include a cart base 42 and a stabilizer ring 43. The stabilizer ring 43 may include a lower half 431 and an upper half 432. The lower half 431 may be attached to the cart base 42 such that the opening of the lower half 431 of the stabilizer ring 43 points upwards. The cart base may include V-groove wheels 45 and jack assemblies 32, 33, and 34 as shown in Figure 2 and as discussed above. The three modules 41 may be connected to form the modular assembly cart 40. The modular assembly cart 40 may be movable on V-tracks 44. A large one-piece fuselage barrel, for example, the fuselage barrel 31 having a diameter of about 19 feet and a length of more than 24 feet, may be inserted into the lower halves 431 of the stabilizer ring 43. Following this, the upper halves 432 of the stabilizer ring 43 may be attached to the lower halves 431 of the stabilizer rings 43. The stabilizer rings 43 may include a plurality of clamps 21, as shown in Figure 1, to clamp the fuselage barrel, such as the fuselage barrel 31, to the stabilizer ring 43. Once the upper halves 432 of the stabilizer rings 43 are attached to the lower halves 431, the stabilizer rings 43 and, therefore, the fuselage barrel (31), may be rotated. Each cart base 42 may have a split design and may include a right half 421 and a left half 422 as shown in Figure 4. After a 90-degree rotation of the stabilizer rings 43, it may be possible to unlock the right half 421 and the left half 422 of the cart base 42 and to move the right half 421 and the left half 422 apart. If needed, for example, for a fuselage barrel having a greater length compared to the fuselage barrel 31, more than 3 modules 41 could be used to form the modular assembly cart.

[038] Referring now to Figure 5, a perspective front view of a two-ring modular assembly cart 50 is illustrated according to one embodiment of the present invention. The two-ring modular assembly cart 50 may include a module 51 and a module 52.
Module 51 and module 52 may be identical. Both module 51 and module 52 may include a cart base 53 and a stabilizer ring 54.

The cart base 53 may have a front 531, a back 532, a top 533, a bottom 534, a left side 535, and a right side 536. The cart base 53 may further include two rails 55. The two rails 55 may be located at the top 533 and may extend longitudinally along the left side 535 and along the right side 536 of the cart base 53, as shown in Figure 5. The cart base 53 may further include at least four casters 29 (also shown in Figure 2) mounted to the bottom 534 of the cart base 53. One casters 29 may be positioned at the left side 535 close to the front 531, another caster 29 may be positioned at the left side 535 close to the back 532, another caster 29 may be positioned at the right side 536 close to the front 531, and another caster 29 may be positioned at the right side 536 close to the back 532. The casters 29 may swivel and may be used to move the module 51 or the module 52 along the factory floor. The cart base 53 may further include at least four jacking cylinders 58. The jacking cylinders 58 may provide vertical translation of the module 51 and the module 52. One jacking cylinder 58 may be positioned at the left side 535 close to the front 531, another jacking cylinder 58 may be positioned at the left side 535 close to the back 532, another jacking cylinder 58 may be positioned at the right side 536 close to the front 531, and still another jacking cylinder 58 may be positioned at the right side 536 close to the back 532. The jacking cylinders 58 may be used to move the cart base 53 vertically up and down. The jacking cylinders 58 may need to be operated in concert such that the fuselage barrel 56 may not be overly stressed while being moved. The waterline plane of the fuselage barrel 56 should not be distorted while being supported by the stabilizer rings 54. The cart base 53 may further include a fuselage support 59. The fuselage support 59 may be installed at the top 533 of the cart base 53. The fuselage support 59 may further be preferably installed at about 5 feet from the front 531 of the cart base 53 and, therefore, inboard of the inside position of the stabilizer ring 54. The fuselage support 59 may be installed such that it may not be in position while the fuselage barrel 56 is loaded into the stabilizer rings 54 or rotating under control of the stabilizer rings 54. Furthermore, the fuselage support 59 may be raised into position to support the fuselage barrel 56 after loading or rotation is completed. The fuselage support 59 may be raised into position in a controlled manner, for example, with load cell indication. The fuselage support 59 may be designed such that it may adapt to a variety of curvatures of fuselage barrels.
56. The surface contact area of the fuselage support 59 with the skin of the fuselage barrel 56 may be such that the elastic limit of the fuselage barrel 56 with frames installed is not exceeded when the fuselage support 59 is supporting the full weight of the fuselage barrel 56 during, for example, repositioning of one of the stabilizer rings 54. For example, the fuselage support 59 may be a roller design as shown in Figures 5 and 6 or a strap design as shown in Figure 7.

[040] The stabilizer ring 54 may include a lower half 541 and an upper half 542. The lower half 541 of the stabilizer ring 54 may be positioned next to the front 531 of the cart base 53. The upper half 542 is detachable from the lower half 531 of the stabilizer ring 53. The upper half 542 of the stabilizer ring 54 may be attached to the lower half 541 after insertion of a fuselage barrel 56 (shown in Figure 5a) such that the lower half 541 and the upper half 542 form the stabilizer ring 54. The fuselage barrel 56, as illustrated in Figure 5a, may be a cured composite fuselage barrel of the center section of a large new generation aircraft, such as the Boeing 7E7 airplane, having a constant contour over the whole length 562. The large one-piece composite fuselage barrel 56 may have a diameter 561 of about 19 feet and a length 562 of more than 24 feet. In this case, both stabilizer rings 54 shown in Figures 5 and 5a may have the same diameter 543. It may further be possible to equip the module 51 with a stabilizer ring 54 having a diameter 543 that is different from the diameter 543 of the stabilizer ring 54 that may be used for module 52. The stabilizer ring 54 may be detachable. Furthermore, the stabilizer ring 54 may be mounted on the rails 55 that allow for about 36 inches of travel from the front 531 towards the back 532 and vice versa. The ring travel may be mechanically assisted but may not need to be precisely controlled or automatically actuated. Module 51 and module 52 may be connected to form the two-ring modular assembly cart 50 by joining the back 532 of the cart base 53 of module 51 with the back 532 of the cart base 53 of the module 52. As shown in Figure 5, the two stabilizer rings 54 may be located at opposite ends of the modular assembly cart 50 supporting the fuselage barrel 56. As shown in Figure 5a, the load position may be outboard with a ring separation 57 of approximately 23 feet. The ring separation 57 may be adjusted according to the length 562 of the fuselage barrel 56. The stabilizer ring 54 may further include a plurality of clamps 21 as shown in Figures 1 and 7 and as described above.

[041] Referring now to Figure 6, a perspective front view of a two-ring modular assembly cart 50 is illustrated according to another embodiment of the present
invention. In addition to the module 51 and the module 52 (as illustrated in Figure 5),
the assembly cart 50 may further include a module 61. The module 61 may include a
cart base 62 having a top 621 and a bottom 622. The cart base 62 may include a
plurality of casters 29 attached to the bottom 622. The casters 29 may swivel and may
be used to move the module 61 along the factory floor. A fuselage support 59 (as
described above) may be attached to the top 621 of the cart base 62, preferably in the
center of the cart base 62. If needed, for example, to support a fuselage barrel 56 that
has a greater length 562 than the fuselage barrel 56 shown in Figure 5a, the modules
51 and 52 may be moved apart from each other and the module 61 may be inserted
between the module 51 and the module 52 to form the two-ring modular assembly cart
50. By providing the modules 51, 52, and 61, as shown in Figures 5 and 6, the two-ring
modular assembly cart 50 may be assembled as needed to support a fuselage barrel of
any shape, for example, the fuselage barrel 31 (shown in Figure 1) of the aft section of
a large new generation aircraft, such as the Boeing 7E7 airplane, the fuselage barrel 39
(shown in Figure 3) of the front section of a large new generation aircraft, such as the
Boeing 7E7 airplane, or the fuselage barrel 56 (shown in Figure 5a) of the center
section of a large new generation aircraft, such as the Boeing 7E7 airplane. It may be
possible to use one or more additional modules 51, 52, and 61. Furthermore, by
providing the module 61, the fuselage barrel 56 may be supported even while detaching
one stabilizer ring 54. Detaching the stabilizer rings 54 from the fuselage barrel 56 may
become necessary for repositioning, for example, to allow access to the areas originally
covered by the stabilizer ring 54 for machining, material testing, or assembly operations.

[042] Referring now to Figure 7, a perspective front view of a two-ring assembly cart
70 with strap fuselage support 71 is illustrated according to another embodiment of the
present invention. The two-ring assembly cart 70 may include a cart base 72 having a
front 721, a back 722, a top 723, and a bottom 724. A first stabilizer ring 54 may be
attached proximate to the front 721 and on top 723 of the cart base 72. A second
stabilizer ring 54 may be attached proximate to the back 722 and on top of the cart base
72. The stabilizer rings 54 may include a lower half 541, an upper half 542, and a
plurality of clamps 21, as described above. The stabilizer rings 54 may also be rotated
after insertion of a fuselage barrel 56. A plurality of V-groove wheels 45 may be
attached to the bottom 724 of the cart base 72 that allow the assembly cart 70 to be
moved along V-tracks 44 (also shown in Figure 4). A plurality of jacking cylinders with
integrated caster wheels 58 may be attached to the front 721 and the back 722 of the
cart base allowing up and down movement of the assembly cart 70. Furthermore, a
strap fuselage support 71 may be mounted to the top 723 of the cart base preferably in
the center between the first stabilizer ring 54 and the second stabilizer ring 54. The
strap fuselage support 71 may provide additional support for stabilizing a one-piece
fuselage barrel 56. Furthermore, by providing the strap fuselage support 71 it may be
possible to detach one of the two stabilizer rings 54 and to reposition the detached
stabilizer ring 54. The strap fuselage support 71 may also be designed as a sling that
may be supported from above by a crane (not shown).

Referring now to Figure 8, a flow chart of a method 80 for stabilizing a large
cured composite fuselage barrel 31 is illustrated according to another embodiment of
the present invention. The method 80 may include the following steps: providing a large
cured composite one-piece fuselage barrel having a diameter of about 19 feet and a
length of more than 24 feet (step 81), such as the fuselage barrel 31 (as shown in
Figure 1), the fuselage barrel 39 (as shown in Figure 3), or the fuselage barrel 56 (as
shown in Figure 5a) and providing a post-cure assembly cart that includes at least two
stabilizer rings (step 82), for example, assembly cart 10 (shown in Figure 1), assembly
cart 30 (shown in Figure 3), assembly cart 40 (shown in Figure 4), assembly cart 50
(shown in Figures 5 and 6), and assembly cart 70 (shown in Figure 7). The method 80
may further include the steps of: opening the stabilizer rings (step 83), such as stabilizer
rings 17, 18, and 19 (Figure 1), stabilizer rings 38 (Figure 3), stabilizer rings 43 (Figure
4) or stabilizer rings 54 (Figures 5, 6 and 7); inserting a fuselage barrel into the open
stabilizer rings (step 84) and closing the stabilizer rings (step 84); and actuating clamps
21 that may be attached to the inner surface of the stabilizer rings (step 85) and,
therefore, attaching the fuselage barrel to the stabilizer rings. It may now be possible to
disassemble and remove the layup mandrel segments from the fuselage barrel (step
86). In step 87, the stabilizers rings, such as the stabilizer rings 17, 18, and 19 (Figure
1) may be rotated while the fuselage barrel 31 is still attached. This allows access to
different parts of the fuselage barrel 31 and further assembly or testing operations may
be conducted in step 88. If an additional fuselage barrel 31 is provided (step 89) and
stabilized with an additional assembly cart 10 (Figure 1), as in, step 91, it may be
possible to mate the two move and align both assembly carts 10 (step 92) for mating of
two adjacent fuselage barrels 31 (step 93). By providing modular assembly carts, such
as assembly cart 40 (Figure 4) or assembly cart 50 Figures 5, 5a, and 6), any shape and size of a composite barrel, for example, fuselage barrels of the aft section, the center section or the forward section of a large new generation aircraft, such as the Boeing 7E7 aircraft, may be stabilized after curing of the composite material.

It should be understood, of course, that the foregoing relates to exemplary embodiments of the invention and that modifications may be made without departing from the spirit and scope of the invention as set forth in the following claims.
WE CLAIM:

1. A one-piece barrel assembly cart, comprising:
   a right assembly cart base having an inner surface;
   a left assembly cart base having an inner surface, wherein said left assembly cart base is joined with said right assembly cart base at said inner surfaces;
   at least two stabilizer rings, wherein each stabilizer ring is divided into a right half and a left half, wherein said right half is attached to said right assembly cart base and wherein said left half is attached to said left cart base; and
   a plurality of clamps being attached to said stabilizer rings.

2. The one-piece barrel assembly cart of claim 1, wherein said right assembly cart base further includes an outer surface and a bottom, and wherein said left assembly cart base further includes an outer surface and a bottom.

3. The one-piece barrel assembly cart of claim 2, further comprising at least six ring guides, wherein at least three of said ring guides are in a fixed connection with said outer surface of said right assembly cart base, wherein at least three of said ring guides are in a fixed connection with said outer surface of said left assembly cart base, and wherein said right halves and said left halves of said stabilizer rings are attached to said ring guides.

4. The one-piece barrel assembly cart of claim 1, wherein said right assembly cart base has the same dimensions as the left assembly cart base.

5. The one-piece barrel assembly cart of claim 1, each of said stabilizer rings includes an inner surface having a diameter and an outer surface having a diameter.

6. The one-piece barrel assembly cart of claim 5, wherein said inner surface fits around a fuselage barrel having diameter of at least 19 feet.

7. The one-piece barrel assembly cart of claim 5, wherein said clamps are attached to said inner surface of each of said stabilizer rings.
8. The one-piece barrel assembly cart of claim 1, further including:
   a plurality of casters attached to said bottom and evenly distributed along
   said outer surface and said inner surface of said right assembly cart base and of said
   left assembly cart base;
   a plurality of support jack assemblies attached to said bottom and evenly
distributed along said outer surface and said inner surface of said right assembly cart
   base and of said left assembly cart base;
   a plurality of pitch and yaw jack assemblies attached to said bottom and
   evenly distributed along said outer surface and said inner surface of said right assembly
cart base and of said left assembly cart base; and
   a plurality of ring support jack assemblies mounted underneath each of
   said stabilizer rings.

9. The one-piece barrel assembly cart of claim 1, wherein said stabilizer
   rings receive a fuselage barrel made out of a cured composite material having a tapered
   shape, an outside, and including longitudinal stiffeners, wherein said clamp attaches to
   said outside of said barrel at a location of said longitudinal stiffener.

10. The one-piece barrel assembly cart of claim 1, wherein said right
    assembly cart base, said left assembly cart base, and said stabilizer rings stabilize a
    composite fuselage barrel having a length of at least 24 feet.

11. A post-cure assembly cart, comprising:
    a track;
    a right sliding base positioned on said track;
    a left sliding base positioned on said track opposite from said right sliding
    base;
    a stabilizer ring having an inner surface and an outer surface and
    including a right half and a left half, wherein said right half is attached to said right
    sliding base and wherein said left half is attached to said left sliding base; and
    a plurality of clamps attached to said inner surface of said stabilizer ring.
12. The post-cure assembly cart of claim 11, further comprising at least one additional track, at least one additional right sliding base, at least one additional left sliding base, and at least one additional stabilizer ring having an outer surface and an inner surface, wherein the total number of right sliding bases equals the total number of left sliding bases, the total number of tracks, and the total number of stabilizer rings.

13. The post-cure assembly cart of claim 11, wherein said track and said additional tracks are connected to expand in longitudinal direction.

14. The post-cure assembly cart of claim 11, wherein said outer surface of said stabilizer ring has the same diameter as said outer surface of said additional stabilizer ring.

15. The post-cure assembly cart of claim 11, wherein the diameter of said inner surface of said stabilizer ring is smaller than the diameter of said inner surface of said additional stabilizer ring.

16. The post-cure assembly cart of claim 11, wherein said stabilizer ring receives a fuselage barrel of the front section of an airplane, and wherein said clamps attach to said fuselage barrel.

17. A modular assembly cart, comprising:
   a first module including a first cart base and a first stabilizer ring;
   a second module including a second cart base and a second stabilizer ring, wherein said second cart base is connected with said first cart base; and
   a third module including a third cart base and a third stabilizer ring, wherein said third cart base is connected with said second cart base.

18. The modular assembly cart of Claim 17, wherein said first module, said second module, and said third module are identical.

19. The modular assembly cart of claim 17, further comprising at least one additional module including an additional cart base and an additional stabilizer ring,
20. The modular assembly cart of Claim 19, wherein said additional module is identical with said first module.

21. The modular assembly cart of Claim 17, wherein said first cart base includes a right half and a left half, wherein said right half and said left half are connected.

22. The modular assembly cart of Claim 17, wherein said first stabilizer ring includes a plurality of clamps, a lower half and an upper half, wherein said lower half is attached to said first cart base with the opening pointing upwards, and wherein said upper half is attached to said lower half.

23. The modular assembly cart of Claim 17, wherein said first stabilizer ring is rotated about 90 degrees.

24. The modular assembly cart of Claim 17, wherein said right half and said left half of said first cart base are unlocked and moved apart, and wherein said lower half of said stabilizer ring is attached to said left half of said first cart base, and wherein said upper half of said stabilizer ring is attached to said right half of said first cart base.

25. The modular assembly cart of Claim 17, wherein said first module, said second module, and said third module include V-groove wheels and are movable along V-tracks.

26. A modular assembly cart, comprising:
   a first module, including:
   a cart base having a front, a back, a top and a bottom;
   two rails located at the top of said cart base and extending longitudinally from said front to said back at opposite sides;
   a stabilizer ring having a lower half and an upper half, wherein said lower half is mounted on said rails proximate to said front of said cart base, and wherein
said upper half is detachable from said lower half; and

- a fuselage support installed on top of said cart base; and
- a second module connected with said first module, wherein said second module is identical with said first module, and wherein said back of said second module is attached to said back of said first module.

27. The modular assembly cart of claim 26, wherein said first and said second module further include a plurality of casters mounted to said bottom of said cart base.

28. The modular assembly cart of claim 26, wherein said cart base further includes at least four jacking cylinders, wherein said jacking cylinders provide vertical translation to said first and said second module.

29. The modular assembly cart of claim 26, wherein said stabilizer ring further includes a plurality of clamps, and wherein said clamps attach to a cured composite fuselage barrel.

30. The modular assembly cart of claim 26, further comprising a third module inserted between said first module and said second module, wherein said third module includes:

- a cart base having a top and a bottom;
- a fuselage support attached to said top of said cart base; and
- a plurality of casters attached to said bottom of said cart base.

31. The modular assembly cart of claim 30, wherein said fuselage support has a roller design.

32. The modular assembly cart of claim 30, wherein said fuselage support has a strap design.
33. A post-cure assembly cart for a fuselage barrel of the aft section of an airplane, comprising:

   a right assembly cart base including an inner surface, an outer surface, and a bottom;

   a left assembly cart base including an inner surface, an outer surface, and a bottom, wherein said left assembly cart base has the same dimensions as the left assembly cart base, and wherein said left assembly cart base is joined with said right assembly cart base at said inner surfaces;

   a plurality of casters attached to said bottom and evenly distributed along said outer surface and said inner surface of said right assembly cart base and of said left assembly cart base;

   a plurality of support jack assemblies attached to said bottom and evenly distributed along said outer surface and said inner surface of said right assembly cart base and of said left assembly cart base;

   a plurality of pitch and yaw jack assemblies attached to said bottom and evenly distributed along said outer surface and said inner surface of said right assembly cart base;

   three ring guides being in a fixed connection with said outer surface of said right assembly cart base;

   three ring guides being in a fixed connection with said outer surface of said left assembly cart base;

   three stabilizer rings, wherein:

   each stabilizer ring has an inner surface and an outer surface,

   each stabilizer ring is divided into a right half and a left half,

   said right half of each stabilizer ring is attached to one of said ring guides of said right assembly cart base,

   said left half of each stabilizer ring is attached to one of said ring guides of said left cart base,

   said right half and said left half of said stabilizer ring are detachable,

   said outer surface of each of said three stabilizer rings has the same diameter, and

   said inner surface of a first stabilizer ring has a first diameter;
said inner surface of a second stabilizer ring has a second
diameter; and
said inner surface of a third stabilizer ring has a third diameter;
a plurality of clamps being attached to said inner surface of said stabilizer
rings; and
a plurality of ring support jack assemblies mounted underneath each of
said stabilizer rings.

34. The post-cure assembly cart of claim 33, wherein said stabilizer rings
receive said fuselage barrel, wherein said clamps attach to said fuselage barrel, and
wherein said ring support jack assemblies rotate said stabilizer rings.

35. The post-cure assembly cart of claim 33, wherein said clamps are force
limiting vacuum toggle clamps, and wherein said clamps are automatically actuated.
36. A method for stabilizing a cured composite fuselage barrel, comprising the steps of:
   providing an assembly cart supporting at least two stabilizer rings including a plurality of clamps, a first half, and a second half;
   opening said stabilizer rings by detaching said first half of each of said stabilizer rings from said second half;
   inserting a fuselage barrel into said stabilizer rings;
   closing said stabilizer rings by connecting said first half of each of said stabilizer rings with said second half; and
   actuating clamps and attaching said fuselage barrel to said stabilizer rings.

37. The method for stabilizing a cured composite fuselage barrel of claim 36, further comprising the step of rotating said stabilizer rings with said fuselage barrel attached.

38. The method for stabilizing a cured composite fuselage barrel of claim 36, further comprising the steps of:
   providing an additional assembly cart stabilizing an additional fuselage barrel;
   aligning said assembly cart and said additional assembly cart using jack assemblies;
   mating said fuselage barrel with said additional fuselage barrel.
Fig. 8

1. PROVIDE A CURED COMPOSITE ONE-PIECE FUSELAGE BARREL
2. PROVIDE A POST-CURE ASSEMBLY CART INCLUDING AT LEAST TWO STABILIZER RINGS
3. OPEN STABILIZER RINGS
4. INSERT FUSELAGE BARREL INTO OPEN STABILIZER RINGS
5. CLOSE RINGS AND ACTUATE CLAMPS TO ATTACH FUSELAGE BARREL TO STABILIZER RINGS
6. DISASSEMBLE AND REMOVE LAYUP MANDREL SEGMENTS FROM FUSELAGE BARREL
7. ROTATE STABILIZER RINGS WHILE FUSELAGE BARREL IS ATTACHED TO PROVIDE ACCESS TO DIFFERENT AREAS OF THE FUSELAGE BARREL
8. PERFORM FURTHER ASSEMBLY AND TESTING OPERATIONS
9. PROVIDE AN ADDITIONAL CURED COMPOSITE ONE-PIECE FUSELAGE BARREL
10. PROVIDE AN ADDITIONAL POST-CURE ASSEMBLY CART INCLUDING AT LEAST TWO STABILIZER RINGS
11. MOVE AND ALIGN BOTH ASSEMBLY CARTS FOR MATING OF ADJACENT FUSELAGE BARRELS
12. MATE ADJACENT FUSELAGE BARRELS
