(54) Title: METHOD AND APPARATUS FOR DETERMINING A PRECODING VECTOR FOR PRECODING DATA TO BE
TRANSMITTED TO A WIRELESS DEVICE IN A WIRELESS COMMUNICATION SYSTEM

(57) **Abrégé/Abstract:**

A Method (100) for determining a precoding vector ($p_{i,opt}$) for precoding data to be transmitted to a wireless device in a wireless communication system comprises receiving (110) first channel state information of a channel between a first wireless device and a first base station in the wireless communication system. The first channel state information is received by the first base station from the first wireless device. Further, the method comprises receiving (120) first channel gain information (h_2) of a channel between a second wireless device and the first base station. The first channel gain information (h_2) is received from the second base station. Additionally, the method (100) comprises receiving (130) a first signal strength parameter (b_i) from the second base station indicating a signal strength at the second wireless device caused by the second base station and receiving (140) a first interference strength parameter (a_i) from the second base station indicating an interference strength at the first wireless device caused by the second base station. Further, the method (100) comprises maximizing (150) a common signal to interference noise ratio parameter ($C, \overline{SINR}, \overline{SINR}_{low}, \overline{SINR}'$) to obtain a precoding vector ($p_{i,opt}$) for precoding data to be transmitted to the first wireless device. The common signal to interference noise ratio parameter ($C, \overline{SINR}, \overline{SINR}_{low}, \overline{SINR}'$) depends on a signal to interference noise ratio ($SINR_1$) at the first wireless device and a signal to interference noise ratio ($SINR_2$) at the second wireless device and is based on the first channel state information, the first channel gain information (h_{21}), the first signal strength parameter (b_i) and the first interference strength parameter (a_i).

Method and Apparatus for Determining a Precoding Vector for Precoding Data to be Transmitted to a Wireless Device in a Wireless Communication System

Abstract

5

A Method (100) for determining a precoding vector ($\mathbf{p}_{i,\text{opt}}$) for precoding data to be transmitted to a wireless device in a wireless communication system comprises receiving (110) first channel state information of a channel between a first wireless device and a first base station in the wireless communication system. The first channel state information is received by the first base station from the first wireless device. Further, the method comprises receiving (120) first channel gain information (h_{21}) of a channel between a second wireless device and the first base station. The first channel gain information (h_{21}) is received from the second base station. Additionally, the method (100) comprises receiving (130) a first signal strength parameter (b_i) from the second base station indicating a signal strength at the second wireless device caused by the second base station and receiving (140) a first interference strength parameter (a_i) from the second base station indicating an interference strength at the first wireless device caused by the second base station. Further, the method (100) comprises maximizing (150) a common signal to interference noise ratio parameter ($C, \overline{\text{SINR}}, \overline{\text{SINR}}_{\text{low}}, \overline{\text{SINR}}'$) to obtain a precoding vector ($\mathbf{p}_{i,\text{opt}}$) for precoding data to be transmitted to the first wireless device. The common signal to interference noise ratio parameter ($C, \overline{\text{SINR}}, \overline{\text{SINR}}_{\text{low}}, \overline{\text{SINR}}'$) depends on a signal to interference noise ratio (SINR_1) at the first wireless device and a signal to interference noise ratio (SINR_2) at the second wireless device and is based on the first channel state information, the first channel gain information (h_{21}), the first signal strength parameter (b_i) and the first interference strength parameter (a_i).

Description

Embodiments according to the invention relate to wireless communication systems and particularly to a method and an apparatus for determining a precoding vector for precoding data to be transmitted to a wireless device in a wireless communication system.

Cellular multiuser multiple-input multiple-output (MIMO) systems are under continuous development for future wireless communication. One topic is the maximization of cell-edge user rates in interference-limited cellular systems. Inter-cell interference (ICI) is the system bottleneck for current cellular networks and many existing methods have tried to mitigate it using different techniques. Users at cell-edges mostly suffer from strong interference of neighbouring base stations and this directly reflects in lower achievable rates.

Fig. 11A shows a schematic illustration of a two-cell MISO (multiple-input single-output) system model for a MISO linear precoding. It shows two base stations BS1, BS2 covering cell 1 and cell 2 and two wireless devices UE1, UE2 (user equipment 1, user equipment 2). Further, Fig. 11B shows the direct links (useful signal) and interfering links (interference) by schematic illustration of the channels between the base stations BS1, BS2 and the wireless devices UE1, UE2, when base station 1 uses beamformer \mathbf{b}_1 and base station 2 uses beamformer \mathbf{b}_2 .

In other words, a two-cell MISO scenario with a single user per cell is considered as shown in Figure 11A, where each BS has M antennas and each receiver at the cell-edge has one antenna. This system model could be also considered as a two-user MISO interference channel (IC), as shown in Figure 12, where a user in the context of ICs denotes a transmitter/receiver pair. Data symbol $s_i \sim \mathcal{N}_{\mathbb{C}}(0, 1)$ ($i = 1, 2$) is linearly precoded by precoder $\mathbf{p}_i \in \mathbb{C}^{M \times 1}$ and transmitted over the channel $\mathbf{h}_{ii} \in \mathbb{C}^{M \times 1}$ to be received by user i . Due to the system nature, it will also be transmitted on channel $\mathbf{h}_{ji} \in \mathbb{C}^{M \times 1}$, $j \neq i$, and received by user j as undesired interference. The transmitted signal is subject to a transmit power constraint $\mathbb{E}[\|\mathbf{p}_i s_i\|_2^2] = E_{\text{tx}_i}$. At the receiver side, the obtained signal is perturbed by noise $n_i \sim \mathcal{N}_{\mathbb{C}}(0, \sigma_i^2)$. Writing the obtained estimates of the data symbols gives:

$$\begin{aligned}\hat{s}_1 &= \mathbf{h}_{11}^T \mathbf{p}_1 s_1 + \mathbf{h}_{12}^T \mathbf{p}_2 s_2 + n_1 \\ \hat{s}_2 &= \mathbf{h}_{22}^T \mathbf{p}_2 s_2 + \mathbf{h}_{21}^T \mathbf{p}_1 s_1 + n_2,\end{aligned}\tag{1}$$

5

where $(\bullet)^T$ denotes transposition.

The most common measure that captures system performance is given by the achievable sum rate C :

10

$$C = \sum_{i=1}^2 \log_2(1 + \text{SINR}_i),\tag{2}$$

where SINR_1 and SINR_2 are the received signal-to-interference noise ratios of receiver 1 and 2, respectively:

15

$$\begin{aligned}\text{SINR}_1 &= \frac{|\mathbf{h}_{11}^T \mathbf{p}_1|^2}{|\mathbf{h}_{12}^T \mathbf{p}_2|^2 + \sigma_1^2} \\ \text{SINR}_2 &= \frac{|\mathbf{h}_{22}^T \mathbf{p}_2|^2}{|\mathbf{h}_{21}^T \mathbf{p}_1|^2 + \sigma_2^2}.\end{aligned}\tag{3}$$

20

In the following, the indices i and j where $i \in \{1, 2\}$ and $j \neq i$.

A known sum rate maximization approach is the distributed interference pricing algorithm described in “D. A. Schmidt, C. Shir, R. A. Berry, M. Honig and W. Utschick, ‘Distributed Resource Allocation Schemes’, IEEE Signal Processing Magazine, Sept. 2009, pp. 53-63”. This iterative method starts with each receiver announcing an interference price to interfering base stations (BSs), assuming cells with single users. In practice, each receiver feeds back these prices to its corresponding base station (BS) and the latter communicates them to other BSs; thus, BS cooperation is required. The interference price of each receiver depends on the initial beamformers of the interfering BSs. Then, each BS separately performs a maximization of its corresponding user rate, taking into account the

25
30

interference prices announced by other receivers and therefore it is a distributed approach. Therefore, it can be thought of as an egoistic approach subject to some penalty paid when causing interference to other users. The maximization results in new beamformers. Next, receivers update their interference prices and new beamformers are again calculated according to the updated interference prices. The process repeats until convergence.

Different approaches for mitigating interference in interference-limited systems have been considered. So far, the best approaches that have been proposed are distributed approaches, in which each transmitter tries to maximize its own rate taking into account interference prices announced by receivers in the system (C. Shi, R. A. Berry and M. Honig, "Distributed Interference Pricing with MISO Channels", in Proc. 46th Annual Allerton Conference 2008, Urbana-Champaign, IL, Sept. 2008, pp. 539-546 and D. A. Schmidt, C. Shir, R. A. Berry, M. Honig and W. Utschick, "Distributed Resource Allocation Schemes", IEEE Signal Processing Magazine, Sept. 2009, pp. 53-63). Formally, interference price π_i represents the marginal decrease in the rate of receiver i following a marginal increase in interference caused by transmitter j , and is defined as:

$$\pi_i = -\frac{\partial u_i}{\partial I_i}, \quad (4)$$

where $u_i = \log_2(1 + \text{SINR}_i)$ is the rate of receiver i and $I_i = |\mathbf{h}_{ij}^T \mathbf{p}_j|^2$ is the interference power present at the receiver i (see equation 3).

Given fixed interference prices, each BS i solves the following problem:

$$\mathbf{p}_{i,\text{opt}} = \underset{\mathbf{p}_i}{\text{argmax}} \quad u_i - \pi_j |\mathbf{h}_{ji}^T \mathbf{p}_i|^2 \quad \text{s.t.} \quad \mathbf{p}_i^H \mathbf{p}_i = E_{\text{tx}_i}, \quad i = 1, 2, \quad (5)$$

where $(\bullet)^H$ denotes conjugate transposition. The objective function of each BS can be viewed as its achievable rate minus the cost of interference it generates to other users. It is an egoistic approach that takes into consideration the penalty paid when causing interference to other users. To implement this algorithm, each receiver should announce an interference price to every interfering BS. In practice, each receiver feeds back these prices to its corresponding base station (BS) and the latter communicates them to other BSs; thus, BS cooperation is required. Given these interference prices, each BS calculates its best

precoder. The algorithm iteratively updates the precoders and interference prices until convergence is reached. To calculate interference prices, every receiver requires the knowledge of useful and interfering signal power. No precoder knowledge at the receiver side is necessary. To calculate optimal precoders, every BS i requires the knowledge of the
 5 channel gains h_{ki} , $k = 1, 2$.

Fig. 11A shows an example for a target configuration in a downlink transmission in a multicell COMP/MIMO system (coordinated multipoint/multiple-input multiple-output system) as described by the distributed interference pricing algorithm. Cooperative
 10 beamforming can be used in order to maximize cell-edge user rates, but the closed form solution does not exist and a signaling overhead results. Fig. 13 schematically illustrates the distributed interference pricing algorithm between two base stations. First an announcement of interference prices p_i penalties is transmitted by the receivers (wireless devices). The interference price represents the marginal decrease in rate for a marginal
 15 increase in interference. Then, the base stations iteratively maximize their own rate taking into account to announce prices p_i , which is an egoistic approach. For example, base station 1 solves the following equation:

$$\underbrace{\log(1 + \text{SINR}_1)}_{\text{Rate user 1}} + \underbrace{f(p_2)}_{\text{penalty}}$$

20

The cooperative beamforming jointly computes b_1 and b_2 to maximize C , but closed form solutions of beamformers do not exist and it is questionable what should be signaled and at which expense (overhead).

25 With this approach a signaling phase before each iteration is necessary. It optimizes iteratively cell-edge user rates subject to interference penalties from neighboring cells. The interference penalties are signaled over the air link and then exchanged over the backhaul (per iteration).

30 Fig. 14 illustrates the initial signaling and the signaling phase of each iteration by a schematic illustration of the channels between two base stations and two wireless devices UE1, UE2. Base station 1 finds b_1 which maximizes the following equation:

$$\underbrace{\log(1 + \text{SINR}_1)}_{\text{Rate user 1}} - \underbrace{p_2 |h_{21}^T b_1|^2}_{\text{penalty due to interference}}$$

(approximated by $|h_{11}^T b_1|^2$)

35

This approach has a slow convergence due to the egoistic approach, needs high computational power, is non-adaptive to fast varying systems, needs additional processing at the receiver side and additional communication via the air link (wireless link).

- 5 It is the object of the present invention to provide an improved concept for determining a pre-coding vector for precoding data to be transmitted to a wireless device in a wireless communication system which allows to increase the data rate achievable for the communication with wireless devices, especially for cell-edge users.
- 10 The object is solved by a method according to claim 1 or an apparatus according to claim 14.

An embodiment of the invention provides a method for determining a precoding vector for precoding data to be transmitted to a wireless device in a wireless communication system.

- 15 The method comprises receiving first channel state information of a channel between a first wireless device and a first base station in a wireless communication system. The first channel state information is received by the first base station from the first wireless device. Further, the method comprises receiving first channel gain information of a channel between a second wireless device and a first base station, receiving a first signal strength
- 20 parameter from the second base station indicating a signal strength at the second wireless device caused by the second base station and receiving a first interference strength parameter from the second base station indicating an interference strength at the first wireless device caused by the second base station. The first channel gain information is received from the second base station. Additionally, the method comprises maximizing a
- 25 common signal to interference noise ratio parameter to obtain a precoding vector for precoding data to be transmitted to the first wireless device. The common signal to interference noise ratio parameter depends on a signal to interference noise ratio at the first wireless device and a signal to interference noise ratio at the second wireless device and is based on the first channel state information, the first channel gain information, the first
- 30 signal strength parameter and the first interference strength parameter.

- Embodiments according to the present invention are based on the central idea that a common signal to interference noise ratio parameter is maximized, which depends on a signal to noise interference noise ratio at the first wireless device and a signal to
- 35 interference noise ratio at the second wireless device, so that the achievable sum rate provided to both wireless devices can be increased. By maximizing the common signal to interference noise ratio parameter, which may be for example the sum rate, the total combined data rate especially of edge users (wireless devices at the edge of a cell) can be

increased, since the interference is mitigated. Further, in comparison to known approaches, less signaling between base stations and wireless devices is required, since a pricing information from the wireless devices is not necessary. Further, a fast convergence of the algorithm can be achieved resulting in less computational effort.

5

In some embodiments according to the invention, the common signal to interference noise ratio parameter represents a sum rate of the first wireless device and the second wireless device, a common signal to interference noise ratio at the first wireless device and the second wireless device or a lower bound of a common signal to interference noise ratio at
10 the first wireless device and the second wireless device.

By using a lower bound of the common signal to interference noise ratio, the computational complexity can be significantly reduced.

25 In the following, the same reference numerals are partly used for objects and functional units having the same or similar functional properties and the description thereof with regard to a figure shall apply also to other figures in order to reduce redundancy in the description of the embodiments.

30 Fig. 1 shows a flow chart of a method 100 for determining a precoding vector $p_{i,\text{opt}}$ for precoding data to be transmitted to a wireless device in a wireless communication system according to an embodiment of the invention. The method 100 comprises receiving 110 first channel state information of a channel between a first wireless device and a first base station in a wireless communication system. This first channel state information is received by the first base station from the first wireless device. Additionally, first channel gain information of a channel between a second wireless device and the first base station is received 120. This first channel gain information is received 120 from the second base station. Further, the method comprises receiving 130 a first signal strength parameter b_i from the second base station indicating a signal strength at the second wireless device

35

caused by the second base station and receiving 140 a first interference strength parameter a_i from the second base station indicating an interference strength at the first wireless device caused by the second base station. Additionally, the method comprises maximizing 150 a common signal to interference noise ratio parameter C , $\overline{\text{SINR}}$, $\overline{\text{SINR}}_{\text{low}}$, $\overline{\text{SINR}}'$ to obtain a precoding $\mathbf{p}_{i,\text{opt}}$ for precoding data to be transmitted to the first wireless device. The common signal to interference noise ratio parameter C , $\overline{\text{SINR}}$, $\overline{\text{SINR}}_{\text{low}}$, $\overline{\text{SINR}}'$ depends on a signal to interference noise ratio SINR_1 (signal to interference and noise ratio at the first wireless device) at the first wireless device and a signal to interference noise ratio SINR_2 (signal to interference and noise ratio at the second wireless device) at the second wireless device. Further, the common signal to interference noise ratio parameter C , $\overline{\text{SINR}}$, $\overline{\text{SINR}}_{\text{low}}$, $\overline{\text{SINR}}'$ is based on the first channel state information, the first channel gain information h_{21} , the first signal strength parameter b_i and the first interference parameter a_i .

By using the precoding vector obtained by using the proposed concept for precoding data for a transmission to a wireless device, the sum rate for providing data to wireless devices in the wireless communication system can be increased, since the interference at two or more wireless devices is considered for the determination of the precoding vector in a way that the sum rate is maximized. For this, channel state information is received from a first wireless device at a first base station and further information and parameters regarding one or more other wireless devices are received from one or more other base stations. With this information a maximization 150 of the common signal to interference noise ratio parameter (also called common signal to interference and noise ratio parameter) over possible precoding vectors can be realized. An interference price information as used by known methods is not necessary. Therefore, the proposed concept may require less signaling between base stations and wireless devices (through the air link or wireless channel).

Although only two base stations and wireless devices are mentioned, the described concept can also be applied to an arbitrary number of base station and wireless devices.

A wireless device is, for example, a mobile phone, a laptop or more general a user equipment UE requiring data through a wireless channel.

The proposed method 100 may be performed preferably at the base station (e.g. at the first base station). Alternatively, the maximization 150 is performed by a central controller receiving the first channel gain information, the first signal strength parameter and the first interference strength parameter. In this case, the first base station may use the first channel state information and the second channel state information to calculate channel gain

information of a channel h_{11} between the first wireless device and the first base station and transmit this channel gain information to the central controller. Alternatively, the first channel state information may be transmitted to the central controller and the corresponding channel gain information may be calculated by the central controller.

5

For example, a channel state information is obtained by a channel vector quantization at the wireless device and comprises a codebook entry together with a channel quality indicator representing an SINR value (signal to interference and noise ratio value). Based on the first channel state information, a channel gain information h_{11} of a channel between
10 the first wireless device and the first base station can be computed. This channel gain information may be a parameter of the common signal to interference noise ratio parameter, so that the common signal to interference noise ratio parameter is based on the first channel state information through this channel gain information.

15 The first channel gain information h_{21} , the first signal strength parameter b_i and the first interference strength parameter a_i may be received through a wireline channel from the second base station (through the backhaul of the wireless communication system). In contrast, the first channel state information is received through a wireless channel (air link) from the first wireless device. Therefore, the necessary data exchange through the wireless
20 channel can be kept low or reduced compared with known methods, since the first channel gain information, the first signal strength parameter and the first interference strength parameter are exchanged through the backhaul of the wireless communication system.

In connection with the proposed concept, a signal strength parameter may indicate in
25 general a signal strength at a wireless device caused by a base station responsible for wireless device (the wireless device is assigned to the base station), when a precoding vector is used, which is used for the calculation of the signal strength parameter. For example, the signal strength parameter comprises a large value for high signal strength and a low value for low signal strength. Further, an interference strength parameter may
30 indicate in general an interference strength at a wireless device caused by a base station not responsible for the wireless device (the wireless device is assigned to another base station), when a precoding vector is used, which is used for the calculation of the interference strength parameter. For example, the interference strength parameter comprises a large value for high interference strength and a low value for low interference strength. Further,
35 an interference strength parameter may indicate not only an interference strength but (a sum of) an interference strength and a noise strength at the wireless device.

The first channel gain information h_{21} , the first signal strength parameter b_i and the first interference strength parameter a_i may be calculated by the second base station before they are transmitted to the first base station. For calculating the first channel gain information h_{21} , the first signal strength parameter b_i and/or the first interference strength parameter a_i ,
5 the second base station may require a channel gain information of a channel between the first wireless device and the second base station. Therefore, method 100 may further comprise receiving second channel state information of a channel between the first wireless device and a second base station in the wireless communication system. The second channel state information may be received by the first base station from the first
10 wireless device. Further, a second channel gain information of the channel between the first wireless device and the second base station may be calculated based on the second channel state information and the second channel gain information h_{12} may be transmitted to the second base station. This may be done by the first base station or the central controller in an alternative implementation mentioned above.

15 In some embodiments according to the invention, the second base station may also perform the method according to the described concept. In this way, both base stations can determine a precoding vector for precoding data to be transmitted to a wireless device assigned to the respective base station by receiving channel state information (first channel
20 state information) from the respective assigned wireless device and receive first channel gain information, a first signal strength parameter and a first interference strength parameter from the other base station.

For this, the base station calculates a signal strength parameter indicating a signal strength
25 at the assigned wireless device caused by itself and an interference strength parameter indicating an interference strength at the other wireless device caused by itself and transmit the calculated signal strength parameter and the calculated interference strength parameter to the other base station.

30 In other words, consistent with the wording above, the method may further comprise calculating a second signal strength parameter b_i indicating a signal strength at the first wireless device caused by the first base station and calculating a second interference strength parameter a_i indicating an interference strength at the second wireless device caused by the first base station. The method may further comprise transmitting the second
35 signal strength parameter b_i and the second interference strength parameter a_i to the second base station. In this way, both base stations can determine a precoding vector by maximizing a common signal to interference noise ratio parameter, so that the achievable sum rate of data to be transmitted to the wireless devices can be increased.

Further, with this approach an iterative optimization of the determined precoding vector can be realized, since each base station can calculate a new interference strength parameter and a new signal strength parameter based on the previously determined precoding vector
 5 and transmit them to the other base station.

In other words, consistent with the wording above, the method may further comprise receiving a third signal strength parameter and a third interference strength parameter a_i from the second base station. The third signal strength parameter b_i may be calculated by
 10 the second base station based on the transmitted second signal strength parameter b_i and the transmitted second interference strength parameter a_i . Further, the third signal strength parameter b_i may indicate a signal strength at the second wireless device caused by the second base station under consideration of the transmitted second signal strength parameter b_i and the transmitted second interference strength parameter a_i . The third interference
 15 strength parameter a_i may be calculated by the second base station based on the transmitted second signal strength parameter b_i and the second interference strength parameter a_i . Further, the third interference strength parameter a_i may indicate an interference strength at the first wireless device caused by the second base station under consideration of the transmitted second signal strength parameter b_i and the transmitted second interference
 20 strength parameter a_i . Additionally, a new precoding vector may be obtained by maximizing the common signal to interference noise ratio parameter, which is now based on the first channel state information, the first channel gain information, the third signal strength parameter and the third interference strength parameter, so that the precoding vector can be optimized iteratively.

25 In this way, the common signal to interference noise ratio parameter still also depends on the first signal strength parameter and the first interference strength parameter, since the third signal strength parameter and the third interference strength parameter are calculated based on the second signal strength parameter and the second interference strength
 30 parameter, which are calculated based on the first signal strength parameter and the first interference strength parameter.

In some embodiments according to the invention the common signal to interference noise ratio parameter may represent a sum rate C of the first wireless device and the second
 35 wireless device, a common signal to interference noise ratio $\overline{\text{SINR}}$ at the first wireless device and the second wireless device or a lower bound of the common signal to interference noise ratio $\overline{\text{SINR}}_{\text{low}}$ at the first wireless device and the second wireless device.

In the following, a detailed example for a method for determining a precoding vector according to the proposed concept is described. The described features may be used together or may be used independent from each other in combination with the basic concept described above. In connection with the detailed example, the proposed concept may also be seen as a direct maximization of the system sum rate with base station cooperation via exchange of interference powers. Some of the explanations below relate to a system with two base stations and two wireless devices, however the applicability of the proposed concept is not limited to such a system and can also be applied to an arbitrary number of base stations and wireless devices.

Fig. 2 shows a general example for a sum rate between two base stations and two wireless devices with an indication of the signal powers S_1, S_2 (signal strength) and the interference powers I_1, I_2 (interference strength) of the two base stations BS1, BS2. In the following, the signal powers S_1, S_2 and the signal strength parameter b_i may be equal quantities, the interference powers I_1, I_2 and the interference strength parameter a_i may be equal quantities and the beamformers $\mathbf{b}_1, \mathbf{b}_2$ and the precoding vectors $\mathbf{p}_1, \mathbf{p}_2$ may be equal quantities.

A direct maximization of the main objective function (see equation 2) is proposed, assuming the BSs can exchange precoder information (this assumption will be relaxed later). To that end, equation 2 is rewritten as:

$$\begin{aligned} C &= \log_2 ((1 + \text{SINR}_1) (1 + \text{SINR}_2)) \\ &= \log_2 (1 + \text{SINR}_1 + \text{SINR}_2 + \text{SINR}_1 \text{SINR}_2) \\ &= \log_2 (1 + \overline{\text{SINR}}), \end{aligned} \tag{6}$$

where $\overline{\text{SINR}}$ is the equivalent SINR of a corresponding single-cell single user system achieving the same rate (e.g. one possible common signal to interference noise parameter). Since the logarithm function is monotonic, maximizing equation 6 is equivalent to maximizing its argument. Thus, the problem of finding the optimal precoders $(\mathbf{p}_1, \mathbf{p}_2)_{\text{opt}}$ can be formulated as follows:

$$(\mathbf{p}_1, \mathbf{p}_2)_{\text{opt}} = \underset{(\mathbf{p}_1, \mathbf{p}_2)}{\text{argmax}} \quad \overline{\text{SINR}} \quad \text{s.t.} \quad \mathbf{p}_i^H \mathbf{p}_i = E_{\text{tx}_i}, i = 1, 2. \tag{7}$$

Each term of $\overline{\text{SINR}}$ (e.g. one possible common signal to interference noise parameter) contains expressions of \mathbf{p}_1 and \mathbf{p}_2 , making the problem structure a complicated one. Thus, a closed form expressions for the optimal precoders may not be available. Therefore, an alternating optimization approach can be followed to find (sub)optimal precoder values. Assume BS i wants to find its optimal precoder \mathbf{p}_i given the knowledge of the precoder of BS j , \mathbf{p}_j . First, SINR_i and SINR_j are rewritten as

10

$$\begin{aligned}\text{SINR}_i &= \frac{\mathbf{p}_i^H \mathbf{h}_{ii}^* \mathbf{h}_{ii}^T \mathbf{p}_i}{|\mathbf{h}_{ij}^T \mathbf{p}_j|^2 + \sigma_i^2} \\ \text{SINR}_j &= \frac{|\mathbf{h}_{jj}^T \mathbf{p}_j|^2}{\mathbf{p}_i^H \mathbf{h}_{ji}^* \mathbf{h}_{ji}^T \mathbf{p}_i + \sigma_j^2},\end{aligned}\tag{8}$$

and define scalars a_i and b_i as

15

$$\begin{aligned}a_i &= |\mathbf{h}_{ij}^T \mathbf{p}_j|^2 + \sigma_i^2 \\ b_i &= |\mathbf{h}_{jj}^T \mathbf{p}_j|^2.\end{aligned}\tag{9}$$

a_i and b_i represent the interference-plus-noise power present at receiver i and the useful signal power of receiver j , respectively, which are known and fixed for a certain value of \mathbf{p}_j . Using these quantities, equation 8 can be rewritten as:

25

$$\begin{aligned}\text{SINR}_i &= \frac{\mathbf{p}_i^H \mathbf{h}_{ii}^* \mathbf{h}_{ii}^T \mathbf{p}_i}{a_i} = \mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i \\ \text{SINR}_j &= \frac{b_i}{\mathbf{p}_i^H \mathbf{h}_{ji}^* \mathbf{h}_{ji}^T \mathbf{p}_i + \sigma_j^2} = \frac{1}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i},\end{aligned}\tag{10}$$

where \mathbf{A}_i and \mathbf{B}_i are the positive-definite matrices given by:

30

$$\begin{aligned}
 A_i &= \frac{\mathbf{h}_{ii}^* \mathbf{h}_{ii}^T}{a_i} \\
 B_i &= \frac{\mathbf{h}_{ji}^* \mathbf{h}_{ji}^T + \frac{\sigma_j^2}{E_{tx_i}} \mathbf{I}_M}{b_i},
 \end{aligned}
 \tag{11}$$

5 where the equality $\mathbf{p}_i^H \mathbf{p}_i = E_{tx_i}$ has been used to obtain the expression for \mathbf{B}_i and \mathbf{I}_M is the identity matrix of size M .

Then, it is easily seen that the objective function $\overline{\text{SINR}}$ of equation 7 can be solely written in terms of precoder \mathbf{p}_i as follows:

10

$$\begin{aligned}
 \overline{\text{SINR}} &= \mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i + \frac{1}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} + \frac{\mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
 &= \frac{\mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i \mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i + 1 + \mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
 &= \frac{\mathbf{p}_i^H (\mathbf{A}_i \mathbf{p}_i \mathbf{p}_i^H \mathbf{B}_i + \frac{1}{E_{tx_i}} \mathbf{I}_M + \mathbf{A}_i) \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
 &= \frac{\mathbf{p}_i^H \mathbf{D}_i \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i},
 \end{aligned}
 \tag{12}$$

15 where the positive-definite matrix \mathbf{D}_i is implicitly defined. This looks similar to a Rayleigh quotient, whose maximizing value is given by the generalized eigenvector corresponding to the maximum generalized eigenvalue (GEV) of matrices \mathbf{D}_i and \mathbf{B}_i . However, \mathbf{D}_i itself is a function of \mathbf{p}_i , and this prevents the usage of the GEV approach. In the following, we two approaches are proposed that simplify $\overline{\text{SINR}}$ and provide feasible solutions to the problem
 20 at hand. Both approaches relate to a lower bounding of the objective function (e.g. the common signal to interference noise parameter). Noting that

$$\begin{aligned}
\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i &= \frac{\mathbf{p}_i^H \mathbf{h}_{ji}^* \mathbf{h}_{ji}^T \mathbf{p}_i + \sigma_j^2}{b_i} \\
&= \frac{|\mathbf{h}_{ji}^T \mathbf{p}_i|^2}{b_i} + \frac{\sigma_j^2}{b_i} \\
&\geq \frac{\sigma_j^2}{b_i}
\end{aligned}
\tag{13}$$

with equality if \mathbf{p}_i is the zero-forcing solution, this allows to lower bound $\overline{\text{SINR}}$ (e.g. one possible common signal to interference noise parameter) as:

$$\begin{aligned}
\overline{\text{SINR}} &= \frac{\mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i \mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i + 1 + \mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
&\geq \frac{\mathbf{p}_i^H \left(\frac{\sigma_j^2}{b_i} \mathbf{A}_i + \frac{1}{E_{\text{tx}_i}} \mathbf{I}_M + \mathbf{A}_i \right) \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
&= \frac{\mathbf{p}_i^H \left(\left(1 + \frac{\sigma_j^2}{b_i}\right) \mathbf{A}_i + \frac{1}{E_{\text{tx}_i}} \mathbf{I}_M \right) \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
&= \frac{\mathbf{p}_i^H \mathbf{D}_{\text{low},i} \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
&= \overline{\text{SINR}}_{\text{low}},
\end{aligned}
\tag{14}$$

10

where the positive-definite matrix $\mathbf{D}_{\text{low},i}$ is implicitly defined. Note that this matrix is independent of \mathbf{p}_i ; thus, the GEV approach can be used to solve the problem. The main problem has been changed since $\overline{\text{SINR}}_{\text{low}}$ – a lower bound for $\overline{\text{SINR}}$ – is maximized instead of directly maximizing $\overline{\text{SINR}}$. This lower bound depends on b_i ; thus it is variable and changes with every iteration. The optimal \mathbf{p}_i can be found as the generalized eigenvector corresponding to the maximum generalized eigenvalue λ_{max} of matrices $\mathbf{D}_{\text{low},i}$ and \mathbf{B}_i :

15

$$\mathbf{D}_{\text{low},i} \mathbf{p}_{i,\text{opt}} = \lambda_{\text{max}} \mathbf{B}_i \mathbf{p}_{i,\text{opt}}.
\tag{15}$$

20

Having found $\mathbf{p}_{i,\text{opt}}$, BS j can now use this updated value to find $\mathbf{p}_{j,\text{opt}}$ using the same procedure as above and this repeats until convergence. The details of this method are listed in the following Algorithm.

5 **Algorithm 1** Maximizing a lower bound on the system sum rate

```

 $\mathbf{p}_1 \leftarrow \mathbf{p}_{1,\text{noncoop}}, \mathbf{p}_2 \leftarrow \mathbf{p}_{2,\text{noncoop}}$ 
 $C_{\text{old}} \leftarrow C(\mathbf{p}_1, \mathbf{p}_2)$  [cf. (2) and (3)]
for  $iter = 1 : max\_nb\_iterations$  do
  for  $i = 1, 2$  do
     $j \leftarrow 3 - i$ 
    compute  $a_i = f(\mathbf{p}_j)$ ,  $b_i = f(\mathbf{p}_j)$ ,  $\mathbf{A}_i = f(a_i)$ ,  $\mathbf{B}_i = f(b_i)$  and  $N_{\text{low},i}$ 
    update  $\mathbf{p}_i$  [cf. (15)]
  end for
  compute  $C_{\text{new}} \leftarrow C(\mathbf{p}_1, \mathbf{p}_2)$ 
  if  $\frac{C_{\text{new}} - C_{\text{old}}}{C_{\text{old}}} < \epsilon$  then
    break
  else  $C_{\text{old}} \leftarrow C_{\text{new}}$ 
  end if
end for

```

The algorithm starts with initial values $\mathbf{p}_{1,\text{noncoop}}$ and $\mathbf{p}_{2,\text{noncoop}}$, which represent the precoder values in case no cooperation takes place; i.e. each BS tries to maximize its own sum rate independently of the other BS. In the main loop, new values of \mathbf{p}_1 and \mathbf{p}_2 are calculated according to the proposed approach at each iteration. The algorithm runs for a maximum of $max_nb_iterations$ iterations if convergence has still not been achieved, and variable ϵ can be set according to the desired convergence accuracy.

15 The problem with $\overline{\text{SINR}}$ is in the $\mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i \mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i$ term, which prevents from obtaining known analytical solution. In the previous approach, this term was lower bounded, transforming it to a second-order valued problem where feasible solutions can be obtained. Let \mathbf{p}_i^n denote the obtained precoder solution after the n -th iteration and assume \mathbf{p}_i^{n+1} is now searched for. Another possible way to calculate \mathbf{p}_i^{n+1} would be to approximate

20 $\mathbf{p}_i^{H,n+1} \mathbf{A}_i \mathbf{p}_i^{n+1} \mathbf{p}_i^{H,n+1} \mathbf{B}_i \mathbf{p}_i^{n+1}$ with either $\mathbf{p}_i^{H,n} \mathbf{A}_i \mathbf{p}_i^n \mathbf{p}_i^{H,n+1} \mathbf{B}_i \mathbf{p}_i^{n+1}$ or $\mathbf{p}_i^{H,n+1} \mathbf{A}_i \mathbf{p}_i^{n+1} \mathbf{p}_i^{H,n} \mathbf{B}_i \mathbf{p}_i^n$. For example, the first approach is considered and note that \mathbf{p}_i^n is given, this implies that $\mathbf{p}_i^{H,n} \mathbf{A}_i \mathbf{p}_i^n$ is now constant. Effectively, we would be actually neglecting the SINR_i term (see equation 11 and 12) and solving the following sub-problem:

25

$$\mathbf{p}_{i,\text{opt}} = \underset{\mathbf{p}_i}{\operatorname{argmax}} \underbrace{\text{SINR}_j + \text{SINR}_i \text{SINR}_j}_{\overline{\text{SINR}'}} \quad \text{s.t.} \quad \mathbf{p}_i^H \mathbf{p}_i = E_{\text{tx}_i}. \quad (16)$$

Note that $\overline{\text{SINR}'}$ (e.g. one possible common signal to interference noise parameter) is actually another lower bound for $\overline{\text{SINR}}$. The new objective function can be rewritten as

$$\begin{aligned} \overline{\text{SINR}'} &= \frac{1}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} + \frac{\mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\ &= \frac{\mathbf{p}_i^H (\mathbf{A}_i + \frac{1}{E_{\text{tx}_i}} \mathbf{I}_M) \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\ &= \frac{\mathbf{p}_i^H \mathbf{D}'_i \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i}, \end{aligned} \quad (17)$$

10

where the iteration index is omitted for simplicity. Since \mathbf{D}'_i is positive-definite then $\mathbf{p}_{i,\text{opt}}$ is given by the generalized eigenvector corresponding to the maximum eigenvalue of matrices \mathbf{D}'_i and \mathbf{B}_i . Comparing the matrix $\mathbf{D}_{\text{low},i}$ from the previous approach with \mathbf{D}'_i , it is seen that the only difference lies in the additional $\frac{\sigma_j^2}{b_i} \mathbf{A}_i$ term present in $\mathbf{D}_{\text{low},i}$. At high SNR (signal to noise ratio), $\sigma_j^2 \rightarrow 0$ and consequently, $\mathbf{D}_{\text{low},i} \rightarrow \mathbf{D}'_i$; thus the two approaches are expected to yield similar solutions.

15

The implementation of the proposed algorithm may require the knowledge of the channel gains $\mathbf{h}_{ki} \forall k = 1, 2$ at BS i . In addition, scalar quantities a_i and b_i need to be available. These scalars depend on \mathbf{p}_j (see equation 9); thus, they can be calculated at BS j and communicated back to BS i instead of directly communicating \mathbf{p}_j , leading to a reduced signaling overhead. One basic difference between the proposed approach and the state-of-the-art approaches — besides the chosen optimization function — is in the information that is being exchanged between BSs: the state-of-the-art exchanges pricing information while the proposed approach exchanges interference powers $a_i \forall i$ (see equation 9), assuming a decentralized system. In comparison with the state-of-the-art approach, exchange of one additional scalar — b_i — between BSs is required, resulting in additional signaling overhead between the BSs, but no processing at the receiver (calculation of interference prices) is required. Moreover, the interference prices need to be fed-back from the receiver side to the BS side first, resulting in additional overhead between the receivers and BSs for

20

25

30

the state-of-the-art approaches. This overhead reduces the available bandwidth for transmission.

Figure 3 shows the signaling required for the proposed method. The initialization phase starts with pilot symbols sent to receivers, which estimate their channels and send them back (the first channel state information, e.g. codebook entry and channel quality indicator, Fig. 3 shows the parameters h_{11} , h_{12} , σ_1^2 derived by the base station from the channel state information) to the corresponding BSs along with their estimated noise powers (this assumption will be relaxed later). Then, the BSs exchange necessary information (e.g. channel gain information h_{ij} and noise σ_i^2) before the algorithm starts. After convergence, data transmission can start. For a two-cell system, the total signaling overhead is identical (similar). Using the state-of-the-art approach, the pricing scalar is fed back to the corresponding BS, which at its turn communicates it to the interfering BS, resulting in signaling of 2 scalar values, as shown in Figure 15 (neglecting the channel signaling for now). The proposed approach directly exchanges the 2 scalar values a_i and b_i between BSs (it can be safely assumed that the noise power density is similar for different receivers in the system; thus, no noise powers need to be fed-back from the receivers to BSs then exchanged between BSs). The signaling dedicated for the channels is also identical, as shown in both figures. Note that the feedback of interference prices is done via the air link, which is less reliable; thus, any small inaccuracies in the fed-back values can have a big effect on the obtained state-of-the-art solutions. On the other hand, exchange of scalars using the proposed method is done via fiber links (where bandwidth is not an issue) and is more reliable. This discussion assumes no quantization: in that case, it would be hard to figure out which method has less signaling since this depends on the codebook sizes of both the precoders and interference prices. Finally, as seen from the diagrams, iterations using the proposed scheme may not need any fed-back information from the receivers and only information between BSs is exchanged, in contrast to the state-of-the-art method where the updated pricing information π_1 and π_2 need to be fed-back from the receivers at each iteration. This makes the proposed algorithm suitable for centralized systems, for example.

As will be provided later in the simulation results, the proposed algorithm has a very fast convergence speed. This results in a big decrease in required computational power and is economically desirable. Moreover, the proposed algorithm is also well-suited for decentralized systems with fast-varying channels, because only limited signaling is required, keeping in mind that each iteration requires a signaling phase. State-of-the-solutions require a lot of iterations and thus a lot of signaling.

Fig. 4 shows a flow chart of a method 400 for determining a precoding vector for precoding data to be transmitted to a wireless device according to an embodiment of the invention. This example is similar to algorithm 1 described above and indicates the cooperation of two base stations according to the described concept.

5

In this example a first base station starts with initially calculating a precoding vector \mathbf{b}_1 (\mathbf{p}_1) and calculates a first signal strength parameter I_1 (b_i) and a first interference strength parameter S_1 (a_i) (which is done by the second base station in the example shown by Fig. 1 and described by the corresponding description) and signals them to the second base station BS2 (which is the first base station shown in Fig. 1). Then the second base station BS2 (the first base station in Fig. 1) maximizes a common signal to interference noise ratio parameter for finding an optimal precoding vector \mathbf{b}_2 (\mathbf{p}_2) based on the first signal strength parameter I_1 and the first interference strength parameter S_1 . Further, it calculates a second signal strength parameter I_2 (b_i) and a second interference strength parameter S_2 (a_i) and signals them to the first base station BS1 (the second base station in the example of Fig. 1).

Next, base station BS1 (the second base station in the example of Fig. 1) maximizes the common signal to interference noise ratio parameter based on the second signal strength parameter I_2 and the second interference strength parameter S_2 to find an optimal precoding vector \mathbf{b}_1 . Further, it calculates a third signal strength parameter I_1 (b_i) and a third interference strength parameter S_1 (a_i) and signals them to the second base station BS2 (which is the first base station in the example of Fig. 1).

If the new precoding vector fulfills a predefined interruption $\frac{C_{\text{new}} - C_{\text{old}}}{C_{\text{old}}} < \epsilon$ criterion or a maximal number of iterations is reached, the algorithm stops and the precoding vectors calculated last at the first base station and the second base station are used for precoding data to be transmitted to the wireless devices.

The reception of the first channel state information of the wireless device at the base station as well as the reception of the first channel gain information are not illustrated in this schematic algorithm, although these steps are also performed.

By using this iterative approach, the sum rate for transmitting data to the wireless devices can be iteratively optimized without requiring further information from the wireless devices (as for example, the interference prices by known concepts), so that the necessary wireless signaling can be kept low. However, the wireless rates (i.e. achievable rates of different users) are higher when compared to existing schemes.

The illustration of the algorithm in Fig. 4 is equivalent to the algorithm illustrated in Fig. 3. Only the indices are slightly different. For example, the precoding vector is indicated by \mathbf{b}_i instead of \mathbf{p}_i , the signal strength parameter (or signal power parameter) by S_i instead of a_i and the interference strength parameter (or interference power parameter) by I_i instead of b_i .

Further, Fig. 5 shows a schematic illustration of two cells of a wireless communication system with base stations causing interference for cell-edge users in the other cell and the signaling of the interference strength parameter I_1, I_2 during the signaling phase in each iteration. This is done through a wireline link between the base stations, so that the air link communication can be reduced.

It illustrates the new signaling scheme which may enable the base stations to calculate the own-caused interference power I . In this way, the base stations may be able to maximize C cooperatively via interference power exchange:

$$C = \log(1 + \text{SINR}_1) + \log(1 + \text{SINR}_2) = f(I_1, I_2).$$

Corresponding to the algorithm shown in Fig. 4 and the schematic illustration of the 2-cell scenario in Fig. 5, Fig. 6 shows a schematic illustration (signaling diagram) of the channels and the data to be exchanged between two base stations and two wireless devices, when using the proposed concept. By initially signaling the channel state information from the wireless devices to the base stations, the base stations can calculate channel gain information for the different channels between the base stations and the wireless devices. Afterwards, during the signaling phase at each iteration, only a wireline link between the base stations may be required, so that the (necessary) air link communication (data) can be reduced at each iteration.

Simulation results are averaged over 5000 independent and identically distributed (IID) channel realizations with mean $\mathbf{0}$ and covariance matrix \mathbf{I} for both direct and interfering links. This captures the performance at cell edge, where a user suffers from interference as strong as the useful signal. The transmit power E_{tx_i} was set to 1, $\forall i$. $M = 2$ antennas were employed at each BS. Figure 7 compares both proposed (lower bounding) approaches, where approaches refer to the method with $\overline{\text{SINR}}$ and refer to the method with $\overline{\text{SINR}}'$, respectively. The method which maximizes a lower bound performs slightly better at low SNR, with both methods yielding similar solutions as the SNR increases, as expected. One of the lower bound approach is used in the subsequent simulations. Figure 8 compares the proposed approach with the distributed pricing approach. For low SNR, the distributed

pricing approach performs slightly better. The proposed approach outperforms the distributed approach starting with an SNR ~ 12 dB. The proposed approach achieves significant spectral efficiency (and subsequently rate) gains with increasing SNR.

5 Figure 9 shows the number of iterations required by the proposed approach and the distributed pricing approach to reach convergence. As seen from the plot, the proposed scheme converges more or less directly after the first iteration, as subsequent iterations only provide negligible improvements. The distributed pricing approach requires a bigger number of iterations to converge. This is due to the fact that the proposed scheme in this
10 example directly maximizes a lower bound on the sum of cell-edge user rates, while the distributed approach maximizes different objective functions separately and this makes convergence slower.

Fig. 10 shows a block diagram of an apparatus 1000 for determining a precoding vector
15 $\mathbf{p}_{i,\text{opt}}$ for precoding data to be transmitted to a wireless device in a wireless communication system according to an embodiment of the invention.

The apparatus 1000 comprises a wireless receiver 1010, a wireline receiver 1020 and a processor 1030. The wireless receiver 1010 and the wireline receiver 1020 are connected to
20 the processor 1030. The wireless receiver 1010 is configured to receive a first channel state information 1002 of a channel between a first wireless device and a first base station in a wireless communication system. The first channel state information 1002 is received by the first base station from the first wireless device. The wireline receiver 1020 is configured to receive a first channel gain information h_{21} of a channel between the second
25 wireless device and the first base station. The first channel gain information h_{21} is received from the second base station. Further, the wireline receiver 1020 is configured to receive a first signal strength parameter b_i from the second base station indicating a signal strength at the second wireless device caused by the second base station. The wireline receiver 1020 is further configured to receive a first interference strength parameter a_i from the second base
30 station indicating an interference strength at the first wireless device caused by the second base station. The processor 1030 is configured to obtain a precoding vector $\mathbf{p}_{i,\text{opt}}$ for precoding data to be transmitted to the first wireless device by maximizing a common signal to interference noise ratio parameter C , $\overline{\text{SINR}}$, $\overline{\text{SINR}}_{\text{low}}$, $\overline{\text{SINR}}'$. The common signal to interference noise ratio parameter depends on a signal to interference noise ratio
35 at the first wireless device and a signal to interference noise ratio at the second wireless device and is based on the first channel state information 1002, the first channel gain information h_{21} , the first signal strength parameter b_i and the first interference strength parameter a_i .

The apparatus 1000 or the components of the apparatus 1000 may comprise one or more additional features or units realizing one or more aspects of the concept described above.

- 5 For example, the apparatus 1000 may comprise a precoder for precoding data to be transmitted to the wireless device. Further, the apparatus 1000 may comprise a transmitter for transmitting the precoded data to the wireless device.

10 The wireless receiver 1010, the wireline receiver 1020, the processor 1030 and/or other optional units of the apparatus 1000 may be independent hardware units or part of a computer, a microcontroller or a digital signal processor as well as a computer program or a software product for running on a computer, a microcontroller or digital signal processor.

15 Some embodiments of the invention relate to a base station comprising an apparatus for determining a precoding vector as described above. For this, the already existing wireless receiver unit, the wireline receiver unit and the processor of the base station may be used. Further, the precoder and/or the transmitter of the base station may be used.

20 Implementing the described concept in a plurality of base stations may enable a cooperative optimization of the used precoding vectors at the different base stations to obtain a maximal sum rate for the plurality of base stations and the supplied wireless devices.

25 Some embodiments of the invention relate to a cooperative rate maximization based on base station exchange of (interference) powers. The new method may be based on an optimization of the sum of cell-edge user rates for the two-cell scenario assuming base station cooperation. The BSs cooperate to maximize the total rate, in comparison to egoistic state-of-the-art methods where each BS egoistically maximizes its own rate. The total rate is first formulated in terms of the base stations' beamformers and the optimal
30 beamformers are iteratively found as follows. At each iteration, one beamformer (say beamformer of BS1) is optimized to maximize a lower bound on the total rate given the knowledge of the other beamformer which is exchanged (say of BS2). In fact, beamformer knowledge is not required as only power levels need to be exchanged. Then, BS2 uses the updated power level information communicated by BS 1 to calculate its own beamformer.
35 This repeats until convergence. Compared with the distributed approach, an additional scalar may be needed to be communicated to each other BS. However, using state-of-the-art methods, interference prices need to be first fed back from receivers to corresponding BSs through the air link. The air link is less reliable; thus, any small inaccuracies in the

fed-back interference prices can have a big effect on the obtained state-of-the-art solutions. This also reduces the bandwidth for data transmission on the air link. Some of the examples described before are based on a multiple-input single-output (MISO) scenario; however, the extension to MIMO scenarios is straightforward. Moreover, extension to
 5 multicell scenarios is possible, e.g., by either carefully selecting subsets of two cells in the system, or in the context of intra-site CoMP where cooperation is based on a 3 cell scenario.

For example, the proposed method achieves higher rates for cell-edge users in medium to
 10 high SNR ranges. The fast convergence of the proposed scheme results in less computational power, which is economically desirable. The proposed scheme requires less signaling between BSs and receivers at the expense of slightly additional signaling between BSs. It doesn't require processing at the receiver side; thus, simple receivers can be used. Moreover, the proposed algorithm is also well-suited for decentralized systems
 15 with fast-varying channels, because only limited signaling is required, keeping in mind that each new iteration requires new signaling.

In other words, a new iterative method is proposed in order to achieve higher rates in cellular networks, namely for cell-edge users which suffer from high interference. The
 20 proposed approach tries to implicitly mitigate interference by maximizing the total combined rate of such users; thus, it is a cooperative approach. Current state-of-the-art methods try to directly suppress interference or maximize rates separately for each user; such approaches are called egoistic. For example, the new method is a coordinated multi-point (CoMP) scheme where the base stations iteratively exchange interference power
 25 information, in contrast to other methods where pricing information calculated at the receiver side is exchanged (limited information about the amount of interference produced by each base station). No joint processing takes place: that is, the base stations (BSs) only cooperate to find their optimal beamformers but they transmit independently, each to its corresponding cell.

30 For example, the proposed method achieves higher rates for cell-edge users at medium to high signal-to-noise ratios (SNRs). The proposed method requires less signaling between receivers and BSs, at the expense of slightly additional signaling between the BSs. Signaling between receivers and BSs is done via the air link and this reduces the
 35 bandwidth for data transmission. Moreover, the air link can be unreliable. On the other hand, signaling between BSs is done via the backhaul link (fiber), where bandwidth is not an issue and signaling is a lot more reliable. Moreover, the proposed scheme doesn't require processing at the receiver side (calculation of pricing information). The fast

convergence of the proposed scheme results in overall less computational power. Less computational power results in lower operational expenses at the base station and is economically desirable. Higher rates at cell-edges result in increased revenues, and in case higher rates are not desired, the same rates can be achieved with lower transmit power, which again saves power expenses at BSs. The proposed algorithm is applicable to centralized as well as decentralized systems. Moreover, the proposed algorithm is well-suited for decentralized systems with fast-varying channels, because only limited signaling is required, keeping in mind that each new iteration requires new signaling. State-of-the-solutions require a lot of iterations and thus a lot of signaling.

The described concept may be used in the field of wireless communication, transmission technology, CoMP transmission (coordinated multipoint transmission) and/or cellular networks and may be applicable to cellular multiuser multiple-input multiple-output (MIMO) systems.

A new method for maximizing the rate of cell-edge users based on base station cooperation is proposed. Inter-cell interference (ICI) is a system bottleneck which severely impacts system performance — especially for cell-edge users — and this results in lower achievable rates. There are many methods in the literature which try to mitigate interference using different approaches: some try to directly suppress interference while others maximize rates separately for each user, therefore being egoistic approaches. The proposed scheme implicitly tries to mitigate interference by maximizing the total combined rate of edge users; thus, it is a cooperative approach. A two-cell multiple-input single-output (MISO) scenario with single user cells is considered, where the base stations (BS) alternately exchange interference power information in order to maximize a lower bound on the total rate. Numerical results show performance improvements for medium and high signal-to-noise (SNR) ratios over state-of-the-art methods. Moreover, the proposed scheme has a fast convergence rate which makes it even more attractive for time-varying systems where only a limited number of iterations can be afforded.

In other words, the proposed concept provides, for example, an algorithm with fast convergence, lower required computation power and low computational complexity, less processing at the receiver side, a reduced communication on the air link, a good adaptivity to fast varying systems and/or also a counteract to increased complexity by lower bounding C (sum rate).

Compared to known concepts, the proposed scheme may require more signaling between the base stations (via backhaul link), but significantly less signaling between base stations

and receivers (via air link) and less or no processing at the receivers. Further, the proposed concept may comprise a high convergence speed, requires low computational effort and comprises a good adaptivity to fast varying scenarios compared to known concepts.

- 5 The increased cell-edge rates due to the proposed concept may cause increased revenues. Further, the lower computation effort may result in lower operational expenses at the base stations.

10 With known concepts, the system total rate cannot be optimized by joint beamforming design of cooperating base stations. In other words, the known methods do not optimize the system total rate. In comparison, the proposed method can iteratively optimize the system total rate subject to power measures (e.g. signal strength and interference strength) from neighboring cells (neighboring base stations). The powers may be measured at the base station and exchanged over the backhaul (per iteration, no signaling over the air link
15 may be necessary). This concept can provide a method to maximize the system total rate in a signaling efficient way.

Known approaches are egoistic (subject to penalties). In comparison, the proposed method can tackle the problem in a new altruistic (cooperative) approach. Each base station tries to
20 maximize the total rate (sum or rates of both users) at once.

It may be one goal to find optimal beamformers (precoding vectors) that maximize the total rate (e.g. Fig. 2).

- 25 Given S_2 and I_2 , base station 1 BS1 can find an optimal beamformer \mathbf{b}_1 that maximizes C , for example. This is similarly done for the base station BS2. Since the optimal beamformers (and thus S and I quantities) are not known, the algorithm may start with initial beamformers and iterates until convergence. The increased complexity may be reduced by lower bounding C (the sum rate).

30

Some embodiments according to the invention relate to a method aiming to maximize the rates of cell-edge users in wireless cellular networks by solving a total rate maximization problem assuming base station cooperation.

- 35 Optionally, the method may further comprise an iterative procedure based on exchange of (interference) powers between the base station in order to calculate the optimal beam forming vectors.

According to another aspect, the iteration procedure is performed in a distributed way over the base stations, requiring signaling over the backhaul connecting the base stations.

5 According to another aspect, a lower bound of the total rate of cell-edge users instead of the exact rate is maximized at each iteration.

Although some aspects of the described concept have been described in the context of an apparatus, it is clear that these aspects also represent a description of the corresponding method, where a block or device corresponds to a method step or a feature of a method
10 step. Analogously, aspects described in the context of a method step also represent a description of a corresponding block or item or feature of a corresponding apparatus.

Depending on certain implementation requirements, embodiments of the invention can be implemented in hardware or in software. The implementation can be performed using a
15 digital storage medium, for example a floppy disk, a DVD, a Blue-Ray, a CD, a ROM, a PROM, an EPROM, an EEPROM or a FLASH memory, having electronically readable control signals stored thereon, which cooperate (or are capable of cooperating) with a programmable computer system such that the respective method is performed. Therefore, the digital storage medium may be computer readable.

20 Some embodiments according to the invention comprise a data carrier having electronically readable control signals, which are capable of cooperating with a programmable computer system, such that one of the methods described herein is performed.

25 Generally, embodiments of the present invention can be implemented as a computer program product with a program code, the program code being operative for performing one of the methods when the computer program product runs on a computer. The program code may for example be stored on a machine readable carrier.

30 Other embodiments comprise the computer program for performing one of the methods described herein, stored on a machine readable carrier.

In other words, an embodiment of the inventive method is, therefore, a computer program
35 having a program code for performing one of the methods described herein, when the computer program runs on a computer.

A further embodiment of the inventive methods is, therefore, a data carrier (or a digital storage medium, or a computer-readable medium) comprising, recorded thereon, the computer program for performing one of the methods described herein.

5 A further embodiment of the inventive method is, therefore, a data stream or a sequence of signals representing the computer program for performing one of the methods described herein. The data stream or the sequence of signals may for example be configured to be transferred via a data communication connection, for example via the Internet.

10 A further embodiment comprises a processing means, for example a computer, or a programmable logic device, configured to or adapted to perform one of the methods described herein.

A further embodiment comprises a computer having installed thereon the computer
15 program for performing one of the methods described herein.

In some embodiments, a programmable logic device (for example a field programmable gate array) may be used to perform some or all of the functionalities of the methods described herein. In some embodiments, a field programmable gate array may cooperate
20 with a microprocessor in order to perform one of the methods described herein. Generally, the methods are preferably performed by any hardware apparatus.

The above described embodiments are merely illustrative for the principles of the present invention. It is understood that modifications and variations of the arrangements and the
25 details described herein will be apparent to others skilled in the art. It is the intent, therefore, to be limited only by the scope of the impending patent claims and not by the specific details presented by way of description and explanation of the embodiments herein.

Claims

What is claimed is:

- 5 1. Method (100) for determining a precoding vector ($\mathbf{p}_{i,\text{opt}}$) for precoding data to be transmitted to a wireless device in a wireless communication system, comprising:

receiving (110) first channel state information of a channel between a first wireless device and a first base station in the wireless communication system, wherein the

10 first channel state information is received by the first base station from the first wireless device;

receiving (120) first channel gain information (h_{21}) of a channel between a second wireless device and the first base station, wherein the first channel gain information

15 (h_{21}) is received from a second base station;

receiving (130) a first signal strength parameter (b_i) from the second base station indicating a signal strength at the second wireless device caused by the second base station;

20 receiving (140) a first interference strength parameter (a_i) from the second base station indicating an interference strength at the first wireless device caused by the second base station; and

25 maximizing (150) a common signal to interference noise ratio parameter ($C, \overline{\text{SINR}}, \overline{\text{SINR}}_{\text{low}}, \overline{\text{SINR}}'$) to obtain a precoding vector ($\mathbf{p}_{i,\text{opt}}$) for precoding data to be transmitted to the first wireless device, wherein the common signal to interference noise ratio parameter ($C, \overline{\text{SINR}}, \overline{\text{SINR}}_{\text{low}}, \overline{\text{SINR}}'$) depends on a signal to interference noise ratio (SINR_1) at the first wireless device and a signal to interference noise ratio (SINR_2) at the second wireless device and is based on the

30 first channel state information, the first channel gain information (h_{21}), the first signal strength parameter (b_i) and the first interference strength parameter (a_i).
2. Method according to claim 1, further comprising:

35 receiving second channel state information of a channel between the first wireless device and a second base station in the wireless communication system, wherein

the second channel state information is received by the first base station from the first wireless device;

calculating a second channel gain information (h_{12}) of the channel between the first wireless device and the second base station based on the second channel state information; and

transmitting the second channel gain information (h_{12}) to the second base station.

3. Method according to claim 2, wherein the first channel state information and the second channel state information are received through a wireless channel from the first wireless device, wherein the first channel gain information (h_{21}), the first signal strength parameter (b_i) and the first interference strength parameter (a_i) are received through a wireline channel from the second base station.

15

4. Method according to one of claims 1 to 3, further comprising:

calculating a second signal strength parameter (b_i) indicating a signal strength at the first wireless device caused by the first base station;

20

calculating a second interference strength parameter (a_i) indicating an interference strength at the second wireless device caused by the first base station; and

transmitting the second signal strength parameter (b_i) and the second interference strength parameter (a_i) to the second base station.

25

5. Method according to claim 4, further comprising:

receiving a third signal strength parameter (b_i) from the second base station, wherein the third signal strength parameter (b_i) is calculated by the second base station based on the transmitted second signal strength parameter (b_i) and the transmitted second interference strength parameter (a_i), wherein the third signal strength parameter (b_i) indicates a signal strength at the second wireless device caused by the second base station under consideration of the transmitted second signal strength parameter (b_i) and the transmitted second interference strength parameter (a_i);

30

35

receiving a third interference strength parameter (a_i) from the second base station, wherein the third interference strength parameter (a_i) is calculated by the second base station based on the transmitted second signal strength parameter (b_i) and the second interference strength parameter (a_i), wherein the third interference strength parameter (a_i) indicates an interference strength at the first wireless device caused by the second base station under consideration of the transmitted second signal strength parameter (b_i) and the transmitted second interference strength parameter (a_i); and

maximizing the common signal to interference noise ratio parameter (C , $\overline{\text{SINR}}$, $\overline{\text{SINR}}_{\text{low}}$, $\overline{\text{SINR}}'$) to obtain a new precoding vector ($\mathbf{p}_{i,\text{opt}}$), wherein the common signal to interference noise ratio parameter (C , $\overline{\text{SINR}}$, $\overline{\text{SINR}}_{\text{low}}$, $\overline{\text{SINR}}'$) is based on the first channel state information, the first channel gain information (h_{21}), the third signal strength parameter (b_i) and the third interference strength parameter (a_i), so that the precoding vector ($\mathbf{p}_{i,\text{opt}}$) is optimized iteratively.

6. Method according to one of claims 1 to 5, wherein the common signal to interference noise ratio parameter (C , $\overline{\text{SINR}}$, $\overline{\text{SINR}}_{\text{low}}$, $\overline{\text{SINR}}'$) represents a sum rate (C) of the first wireless device and the second wireless device, a common signal to interference noise ratio ($\overline{\text{SINR}}$) at the first wireless device and the second wireless device or a lower bound of a common signal to interference noise ratio ($\overline{\text{SINR}}_{\text{low}}$) at the first wireless device and the second wireless device.

7. Method according to claim 6, wherein the common signal to interference noise ratio ($\overline{\text{SINR}}$) is defined by

$$\overline{\text{SINR}} = \text{SINR}_1 + \text{SINR}_2 + \text{SINR}_1 \text{SINR}_2$$

wherein SINR_1 is a signal to interference noise ratio at the first wireless device and SINR_2 is a signal to interference noise ratio at the second wireless device.

8. Method according to claim 6, wherein the lower bound of the common signal to interference noise ratio ($\overline{\text{SINR}}_{\text{low}}$) is defined by

35

$$\begin{aligned}
\overline{\text{SINR}} &= \frac{\mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i \mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i + 1 + \mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
&\geq \frac{\mathbf{p}_i^H \left(\frac{\sigma_j^2}{b_i} \mathbf{A}_i + \frac{1}{E_{\text{tx}_i}} \mathbf{I}_M + \mathbf{A}_i \right) \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
&= \frac{\mathbf{p}_i^H \left(\left(1 + \frac{\sigma_j^2}{b_i}\right) \mathbf{A}_i + \frac{1}{E_{\text{tx}_i}} \mathbf{I}_M \right) \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
&= \frac{\mathbf{p}_i^H \mathbf{D}_{\text{low},i} \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
&= \overline{\text{SINR}}_{\text{low}},
\end{aligned}$$

with

$$\begin{aligned}
\mathbf{A}_i &= \frac{\mathbf{h}_{ii}^* \mathbf{h}_{ii}^T}{a_i} \\
\mathbf{B}_i &= \frac{\mathbf{h}_{ji}^* \mathbf{h}_{ji}^T + \frac{\sigma_j^2}{E_{\text{tx}_i}} \mathbf{I}_M}{b_i},
\end{aligned}$$

5

and

$$\begin{aligned}
a_i &= |\mathbf{h}_{ij}^T \mathbf{p}_j|^2 + \sigma_i^2 \\
b_i &= |\mathbf{h}_{jj}^T \mathbf{p}_j|^2.
\end{aligned}$$

10

wherein $\overline{\text{SINR}}$ is a common signal to interference noise ratio, index i and j are equal to 1 or 2 with i being unequal to j , \mathbf{p}_i , \mathbf{p}_j are precoding vectors of the first base station or the second base station, \mathbf{h}_{ii} , \mathbf{h}_{ij} , \mathbf{h}_{ji} and \mathbf{h}_{jj} are channel gain information of a channel between a base station and a wireless device, σ_i^2 is the noise power, \mathbf{I}_M is the identity matrix of size M , E_{tx_i} is the transmit power, a_i is an interference strength parameter and b_i is a signal strength parameter.

15

9. Method according to claim 6, wherein the lower bound of the common signal to interference ratio ($\overline{\text{SINR}}$) is defined by

20

$$\begin{aligned}
\overline{\text{SINR}}' &= \frac{1}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} + \frac{\mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
&= \frac{\mathbf{p}_i^H \left(\mathbf{A}_i + \frac{1}{E_{\text{tx}_i}} \mathbf{I}_M \right) \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\
&= \frac{\mathbf{p}_i^H \mathbf{D}_i' \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i},
\end{aligned}$$

with

$$\begin{aligned}
\mathbf{A}_i &= \frac{\mathbf{h}_{ii}^* \mathbf{h}_{ii}^T}{a_i} \\
\mathbf{B}_i &= \frac{\mathbf{h}_{ji}^* \mathbf{h}_{ji}^T + \frac{\sigma_j^2}{E_{\text{tx}_i}} \mathbf{I}_M}{b_i},
\end{aligned}$$

and

$$\begin{aligned}
a_i &= |\mathbf{h}_{ij}^T \mathbf{p}_j|^2 + \sigma_i^2 \\
b_i &= |\mathbf{h}_{jj}^T \mathbf{p}_j|^2.
\end{aligned}$$

wherein $\overline{\text{SINR}}'$ is a common signal to interference noise ratio, index i and j are equal to 1 or 2 with i being unequal to j , \mathbf{p}_i , \mathbf{p}_j are precoding vectors of the first base station or the second base station, \mathbf{h}_{ii} , \mathbf{h}_{ij} , \mathbf{h}_{ji} and \mathbf{h}_{jj} are channel gain information of a channel between a base station and a wireless device, σ_i^2 is the noise power, \mathbf{I}_M is the identity matrix of size M , E_{tx_i} is the transmit power, a_i is an interference strength parameter and b_i is a signal strength parameter.

10. Method according to one of claims 1 to 9, wherein the first signal strength parameter (b_i) is defined by

$$b_i = |\mathbf{h}_{jj}^T \mathbf{p}_j|^2.$$

wherein index i and j are equal to 1 or 2 with i being unequal to j , \mathbf{p}_j are precoding vectors of the first base station or the second base station and \mathbf{h}_{jj} are channel gain information of a channel between a base station and a wireless device.

11. Method according to one of claims 1 to 10, wherein the first interference strength parameter (a_i) is defined by

$$a_i = |\mathbf{h}_{ij}^T \mathbf{p}_j|^2 + \sigma_i^2$$

5

wherein index i and j are equal to 1 or 2 with i being unequal to j , \mathbf{p}_j are precoding vectors of the first base station or the second base station, \mathbf{h}_{ij} are channel gain information of a channel between a base station and a wireless device and σ_i^2 is the noise power.

10

12. Method according to one of claims 1 to 11, wherein the maximization is done by solving a generalized eigenvector vector problem, wherein the precoding vector ($\mathbf{p}_{i,\text{opt}}$) for precoding data is the eigenvector corresponding to the maximum generalized eigenvalue (λ_{\max}) of matrices ($\mathbf{D}_{\text{low},i}$, \mathbf{B}_i) depending on the first channel state information, the first channel gain information (\mathbf{h}_{21}), the first signal strength parameter (b_i) and the first interference strength parameter (a_i).

15

13. Method according to claim 12, wherein the generalized eigenvector problem to be solved is

20

$$\mathbf{D}_{\text{low},i} \mathbf{p}_{i,\text{opt}} = \lambda_{\max} \mathbf{B}_i \mathbf{p}_{i,\text{opt}}.$$

wherein $\mathbf{D}_{\text{low},i}$ is defined by

25

$$\begin{aligned} \overline{\text{SINR}} &= \frac{\mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i \mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i + 1 + \mathbf{p}_i^H \mathbf{A}_i \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\ &\geq \frac{\mathbf{p}_i^H \left(\frac{\sigma_i^2}{b_i} \mathbf{A}_i + \frac{1}{E_{\text{tx},i}} \mathbf{I}_M + \mathbf{A}_i \right) \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\ &= \frac{\mathbf{p}_i^H \left(\left(1 + \frac{\sigma_i^2}{b_i} \right) \mathbf{A}_i + \frac{1}{E_{\text{tx},i}} \mathbf{I}_M \right) \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\ &= \frac{\mathbf{p}_i^H \mathbf{D}_{\text{low},i} \mathbf{p}_i}{\mathbf{p}_i^H \mathbf{B}_i \mathbf{p}_i} \\ &= \overline{\text{SINR}}_{\text{low}}, \end{aligned}$$

with

$$A_i = \frac{\mathbf{h}_{ii}^* \mathbf{h}_{ii}^T}{a_i}$$

$$B_i = \frac{\mathbf{h}_{ji}^* \mathbf{h}_{ji}^T + \frac{\sigma_j^2}{E_{tx_i}} \mathbf{I}_M}{b_i},$$

5

$$a_i = |\mathbf{h}_{ij}^T \mathbf{p}_j|^2 + \sigma_i^2$$

$$b_i = |\mathbf{h}_{jj}^T \mathbf{p}_j|^2.$$

10 wherein $\overline{\text{SINR}}$ is a common signal to interference noise ratio, index i and j are equal to 1 or 2 with i being unequal to j , \mathbf{p}_i , \mathbf{p}_j are precoding vectors of the first base station or the second base station, \mathbf{h}_{ii} , \mathbf{h}_{ij} , \mathbf{h}_{ji} and \mathbf{h}_{jj} are channel gain information of a channel between a base station and a wireless device, σ_i^2 is the noise power, \mathbf{I}_M is the identity matrix of size M , E_{tx_i} is the transmit power, a_i is an interference strength parameter and b_i is a signal strength parameter.

15

14. Apparatus (1000) for determining a precoding vector ($\mathbf{p}_{i,\text{opt}}$) for precoding data to be transmitted to a wireless device in a wireless communication system, the apparatus comprising:

20

a wireless receiver (1010) configured to receive a first channel state information of a channel between a first wireless device and a first base station in the wireless communication system, wherein the first channel state information is received by the first base station from the first wireless device;

25

a wireline receiver (1020) configured to receive a first channel gain information (h_{21}) of a channel between the second wireless device and the first base station, wherein the first channel gain information (h_{21}) is received from a second base station, wherein the wireline receiver (1020) is configured to receive a first signal strength parameter (b_i) from the second base station indicating a signal strength at the second wireless device caused by the second base station, wherein the wireline receiver (1020) is further configured to receive a first interference strength

30

parameter (a_i) from the second base station indicating an interference strength at the first wireless device caused by the second base station; and

5 a processor (1030) configured to obtain a precoding vector ($\mathbf{p}_{i,\text{opt}}$) for precoding data to be transmitted to the first wireless device by maximizing a common signal to interference noise ratio parameter ($C, \overline{\text{SINR}}, \overline{\text{SINR}}_{\text{low}}, \overline{\text{SINR}}'$), wherein the common signal to interference noise ratio parameter ($C, \overline{\text{SINR}}, \overline{\text{SINR}}_{\text{low}}, \overline{\text{SINR}}'$) depends on a signal to interference noise ratio at the first wireless device and a signal to interference noise ratio at the second wireless device and is based on the
10 first channel state information, the first channel gain information (h_{21}), the first signal strength parameter (b_i) and the first interference strength parameter (a_i).

15. Computer program with a program code for performing the method according to one of the claims 1 to 13, when the computer program runs on a computer or a
15 microcontroller.

FIGURE FOR ABSTRACT

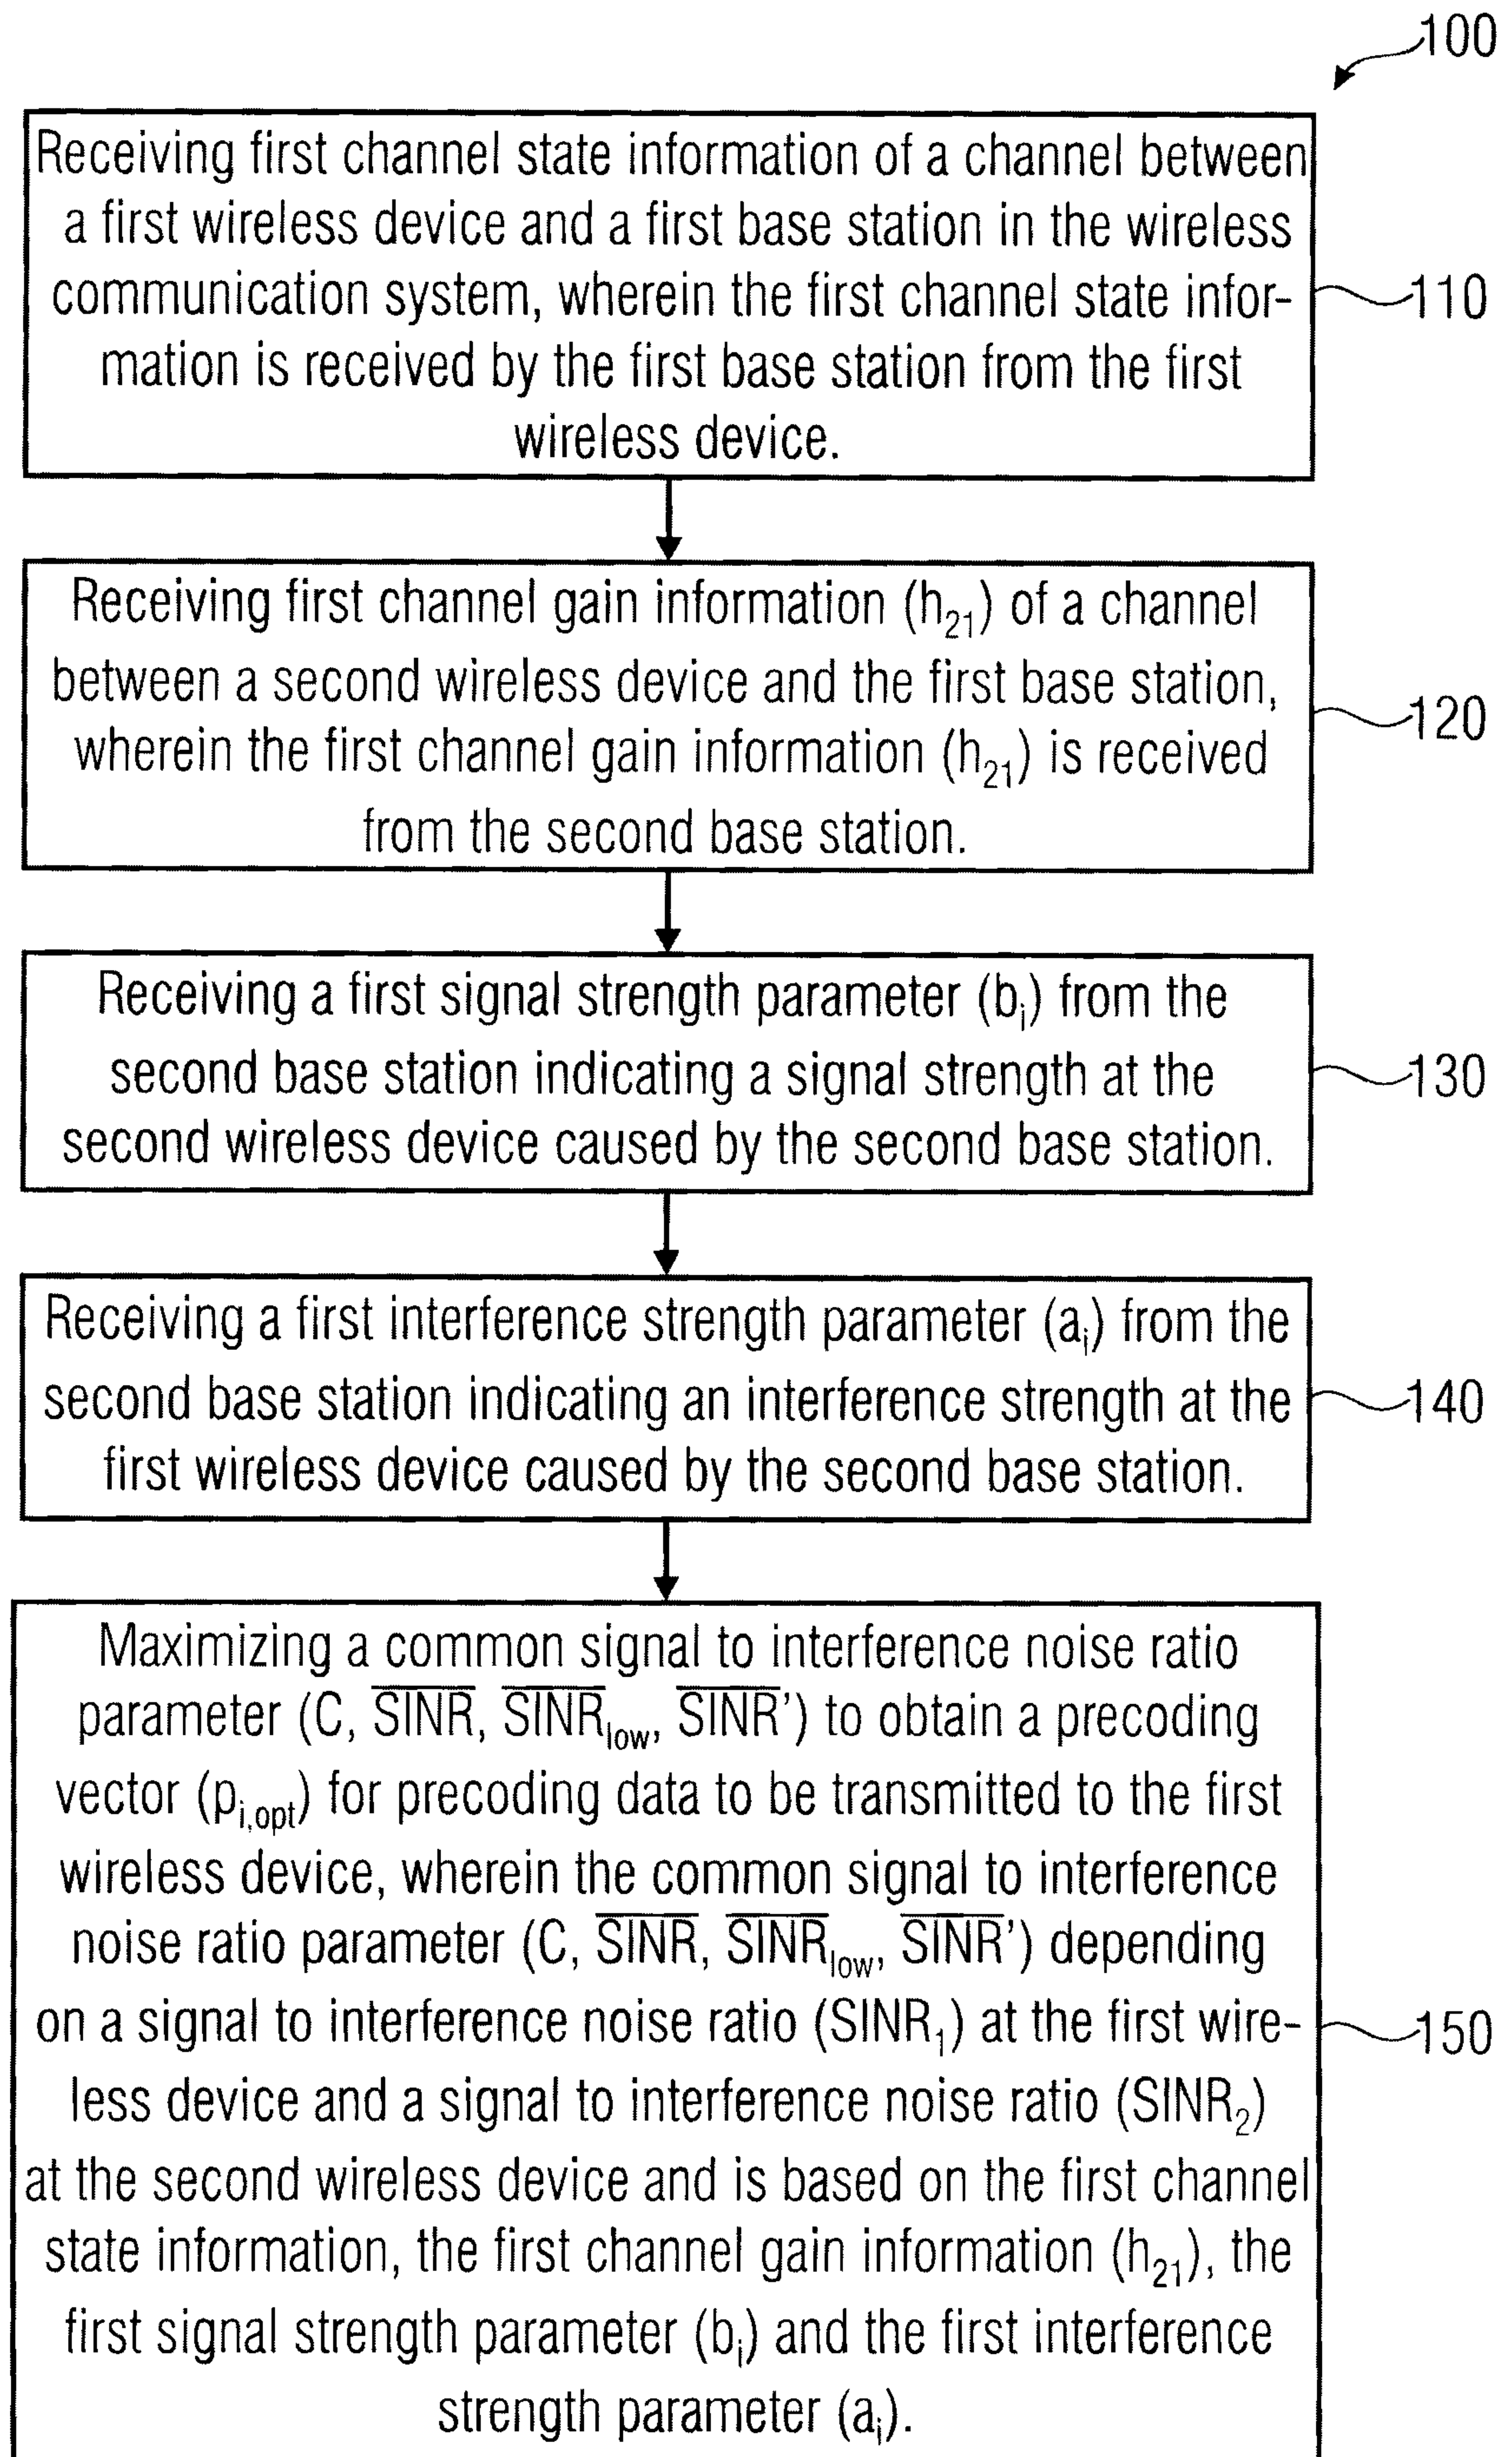

FIG 1

100

110

Receiving first channel state information of a channel between a first wireless device and a first base station in the wireless communication system, wherein the first channel state information is received by the first base station from the first wireless device.

120

Receiving first channel gain information (h_{21}) of a channel between a second wireless device and the first base station, wherein the first channel gain information (h_{21}) is received from the second base station.

130

Receiving a first signal strength parameter (b_i) from the second base station indicating a signal strength at the second wireless device caused by the second base station.

140

Receiving a first interference strength parameter (a_i) from the second base station indicating an interference strength at the first wireless device caused by the second base station.

150

Maximizing a common signal to interference noise ratio parameter ($C, \overline{\text{SINR}}, \overline{\text{SINR}}_{\text{low}}, \overline{\text{SINR}}'$) to obtain a precoding vector ($p_{i,\text{opt}}$) for precoding data to be transmitted to the first wireless device, wherein the common signal to interference noise ratio parameter ($C, \overline{\text{SINR}}, \overline{\text{SINR}}_{\text{low}}, \overline{\text{SINR}}'$) depending on a signal to interference noise ratio (SINR_1) at the first wireless device and a signal to interference noise ratio (SINR_2) at the second wireless device and is based on the first channel state information, the first channel gain information (h_{21}), the first signal strength parameter (b_i) and the first interference strength parameter (a_i).
